W. H. C., GENEVA, N. Y. When will our readers comprehend or understand the nature of kerosene and naphtha? If our correspondent has been an "attentive reader of the JOURNAL from the start," as he remarks, he must have read our statements, several times repeated, that all peddlers and advertisers who claim to have discovered *safe, inexplosive burning fluids and oils*, and who offer them for sale, or recipes to manufacture such, are charlatans and cheats. It is impossible to render the light, cheap naphthas distilled from petroleum safe to use for illuminating purposes, and the travelling and advertising rascals who deceive the public by statements to the contrary ought to be put in the penitentiary.

N. S. F., WINDSOR, N. Y. Coal ashes, from anthracite, contain about 5 per cent. of soluble fertilizing material. The remainder is principally silex, and incombustible substances which are of no special advantage to soils.

I. R. F., MANISTEE, MICH. Use the ashes from the mill freely, and it will prove of great service to your lands.

C. R. C., WINSTED, CONN. The removal of iron stains from cotton and linen is a matter of some difficulty if they have remained on the fabric for some time. Oxalic acid, which is usually employed for the purpose, is liable to injure the fibre of the cloth, if the solution is sufficiently concentrated, and applied long enough to accomplish the end. The following method (which we believe, has never been published in this country) will remove old stains promptly without injury to the fabric: Wet the mark with yellow sulphide of ammonium, by which it will be immediately blackened, and allow it a minute or so to penetrate; then wash out the excess of sulphide, and treat the black spot with cold dilute muriatic acid, by which it is immediately removed. Finally, wash well with water.

"INQUIRER," WHEELING, W. Va., wishes to know what is "the very best recipe for making a polish or gloss for shirt bosoms, etc." Can any of our readers furnish it?

R. C. KEDZIE, of LANSING, sends us $1.00, but forgets to mention his State. There are at least four post-offices of that name, and we have no means of knowing which is meant.

W. H. HARLOW, Postmaster at "Boston Junction," sends us an official notice, but does not give the State. There is no such post-office on our list, nor can we find it in the P. O. Directory.

A FRIEND in VINELAND, N. J., formerly of Waterville, Me., sends 50 cents, but neglects to sign his name.

Such omissions are not uncommon in the letters we receive. In many cases we can find some way of supplying them, but in others we have no clue to guide us. Our friends should be careful to give their address *in full;* and where a change is to be made in mailing the paper, *both the old and the new address* should be given.

Medicine.

THERAPEUTICAL IMPORTANCE OF MANGANESE.

THE medical and scientific journals have recently announced as a "new discovery," that Prof. Polucci, of Italy, has detected the presence of manganese in the human blood. We are surprised at this, since it has been known for at least a quarter of a century that manganese was a normal constituent of the blood, and also that it exists in a multitude of plants and in milk. Indeed, as long ago as 1774, Scheele and Gahn showed that manganese is associated with iron in organic nature. In 1830, Wurzer found it in burnt bones. Millon in 1847, Marchesan in 1848, and Hanon in 1849, stated after much research, that manganese is the constant and natural associate of iron in the blood. The discovery of Prof. Polucci is therefore not very *new.* It is probable, however, that he has made quite extensive researches in this direction, and that the results of other chemists are fully confirmed by them. In 20 analyses of the blood of persons of different sexes and conditions, and in 23 analyses of human milk, the manganese element was constantly observed.

We have long entertained the opinion that manganese is an important therapeutical agent, and that in some cases of chlorosis where iron fails to exert a curative influence, good effects result from the employment of manganese. Physicians are often puzzled to understand why some of their chlorotic patients are benefited by iron, and others not. Now there is good reason to believe that many instances of "impoverishment of the blood," do not so much depend upon a deficiency of iron as of its associate, manganese. It is certain that most cases of the kind commence to improve as soon as manganese is administered. With Dr. Hanon we are almost led to believe that there are two kinds of chlorosis, one arising from a deficiency of iron, the other from a deficiency of manganese.

We believe, also, that, like iron, manganese has a peculiar tonic effect which is independent of its action in supplying deficiencies in the blood, and in this respect it is a useful remedy. So impressed were we two years since with the great importance of a ferro-manganic preparation both pleasant and effective, that we set about making some laboratory experiments with the view of devising one. We succeeded in prepar-

ing a double salt of iron and manganese, which consists of 75 parts of citrate of sesquioxide of iron, and 25 parts of citrate of *protoxide* of manganese. This beautiful preparation is in the form of garnet-colored scales, perfectly soluble in cold water, and almost tasteless. We believe that this combination has never been successfully made before, either in this country or in Europe, although it has been often attempted. The manganese salt is maintained in the form of a *protoxide*, which is an advantage of the first importance. In this ferro-manganic preparation a remedy is provided which meets most effectively chlorotic cases, whether they arise from want of iron or manganese in the circulation. It is worthy the attention of physicians everywhere.

THE MICROSCOPE IN MEDICINE.

THE debt which modern medicine, both theoretical and practical, owes to the microscope can hardly be overestimated, and yet the value of the instrument for clinical purposes is not so generally appreciated by physicians as it ought to be. Many are too ready to sneer at it as a mere plaything, and to deny that it is of real service in the every-day work of a medical man. To such skeptics we commend the following extracts from a chapter on the microscope in a recent work by Prof. Bennett of the University of Edinburgh: —

"Some years ago I was summoned to see a Dispensary patient laboring under bronchitis, who was spitting florid blood. On examining the sputum with a microscope, I found that the colored blood corpuscles were those of a bird. On my telling her she had mixed a bird's blood with the expectoration, her astonishment was unbounded, and she confessed that she had done so for the purpose of imposition.

"A boy was brought to me with an eruption on the scalp, which was of so indefinite a character that its nature could not be determined. He had lately been elected to occupy a vacancy in one of our educational charitable establishments, and the question to decide was, whether the disease was or was not contagious. On examining the scalp with a microscope, I readily discovered the *Achorion Schoenlenci*, or fungus constituting true favus, and as this has been experimentally proved to be inoculable, I had no hesitation in preventing his admission into the school.

"A child was brought to me said to be affected with worms, because it passed yellow shreds in abundance, which, to the naked eye, closely resembled ascarides. All kinds of vermifuge remedies had been tried in vain. On examining the shreds with a microscope, I found them to consist of undigested spinal vessels of plants, and they ceased to appear when the vegetable broth used as food was abandoned.

"An individual was supposed to be laboring under dysentery, from the frequent passage of yellowish pulpy masses in the stools, accompanied with tormina and other symptoms. On examining these masses with the microscope, I found them to consist of undigested potato skins. On inquiry it was found that this person had eaten the skins with the potatoes. On causing these to be removed before dinner, the alarming appearance ceased, and the other symptoms also disappeared.

"An elderly lady conceived herself to be affected with insects continually forming on the skin, which produced incessant itching and tingling. All the hair was removed, and every kind of application was tried without effect. On rubbing the surface she always saw minute white rolls and black specks, which she regarded as insects in different stages of development. The torment and anxiety this caused her for many months it is scarcely possible to conceive. At length she labored under the idea that she was communicating the disease to her husband and daughter, when, at the request of her medical attendant in the west of Scotland, she came to Edinburgh in order that I might investigate and treat it. I had the pleasure of showing this lady, under the microscope, that the white bodies were minute rolls of epidermis or of the cotton cloth with which she rubbed the skin, and that the black specks were portions of dust or soot. Her hallucination being in this way dissipated, she returned home perfectly well."

HOW DOES CHLORAL INDUCE SLEEP?

BY Z. C. M'ELROY, M. D., ZANESVILLE, OHIO.

To the physicist, the human body is presented as a simple dynamic problem. The mechanical, sensory, thermal, emotional, and intellectual phenomena evolved by any living being are due to, or are co-incident with chemical changes of matter, and, most likely, always the decay or oxidation of its tissues. The food eaten must be transformed into organic forms, or tissues, and chemical change of matter must occur, and that always in the interest of decay, simultaneously with the evolution of any of these vital phenomena.

Throughout the domain of physical science, these premises, if drawn from anything else in the universe than the human body, would warrant the induction that the physical and physiological unities of organic life are *form* and *motion:* that is, that the materials of a human body must have definite forms; and motion, or chemical changes, must occur in the molecular structure of the forms, as fundamental conditions for the performance of a function. But until recently, the boldest scientists have hesitated to apply physical methods, and physical laws, towards the solution of the phenomena of organic life. But it is done now, and with results so much more satisfactory than by past methods, that its general adoption cannot be long delayed.

In the investigation of any complexity, when the ultimate units, or simples, have been reached by the physicist, further progress in experiment and induction is beset with fewer difficulties and rewarded with greater certainties or truths as results. From these unities and other known phenomena, probabilities, possibilities, improbabilities, and impossibilities can be predicted with nearly absolute scientific accuracy. Thus, it is scientifically possible, probable, and almost, if not quite, certain, that during the transformation of food into tissue forms, force is conserved, or locked up, as it were, in their chemical structure, to be evolved as the dynamics of organic life by their molecular decay or oxidation. A further induction, with nearly the same scientific accuracy and certainty, would be that the sole power of therapeutic agents would be in the influence they exercise over these physical units of form and motion — sometimes, as by so called caustics, in the destruction of the forms; but mainly over that of motion, or chemical changes, though each finally merges into motion. Neither the empirical experimenter, physicist, or chemist, either by accident or design, has ever been able to produce or construct an organic form, which evolved an organic function; for the records of pathology show conclusively that material form and function are inseparably connected in organized life, and that with loss of form, and precisely to the extent of loss of form, function ceases, and, in most cases, ceases forever. And with motion above or below normal velocity, function is proportionately deranged, and forms endangered.

From these facts and inductions, the only scientific probability or possibility in reference to the modus operandi of chloral in inducing sleep is, that it retards motion, or chemical changes in the forms of the human body, both in the interest of repair and decay, or waste. The chemical changes or motion of matter, upon which the phenomena of life are dependent, are reduced, or retarded to the minimum compatible with their continuance and resumption of normal activity; the machinery, so to speak, is simply held in check, to resume its working, as if no interruption had taken place, after a certain time, and under certain conditions, which is precisely the character of the chloral sleep, as pointed out by Dr. Nichols. It is further scientifically possible, and probable, if not absolutely certain, that the only results any mode of force directly, or indirectly, in chemical combinations of matter, can produce in a living human body are as follows: —

1. Promoting motion, in the interest of repair or decay;
2. Retarding motion, in the interest of repair or decay;
3. Changing the forms of the tissues.

At least, into one or the other, or some combination of these three results, can be merged every effect that can be made to occur in a living human body.

Does a chemical combination of matter promote motion in the interest of decay beyond a certain velocity, it is designated as an active or deadly poison, as strychnia. Does any retard motion below a certain velocity, it is likewise called an active poison, as prussic acid, etc. Does any organic compound, as the virus of serpents, small-pox, scarlatina, etc., or any product of chemical laboratories, as caustics, calomel, etc., change forms, it is called a poison too.

It seems, therefore, sufficient to satisfy scientific accuracy, to refer the modus operandi of chloral, in certain doses, simply to the retarding of motion to the minimum compatible with its resumption, in the shortest time, and with the greatest safety and comfort, — greater indeed than any other known agents.

IMPURITIES IN DISTILLED WATER.

ONE of the intensely interesting questions of the day is the germ theory of disease — that is, that many diseases have their origin from organic germs floating in the air. Another, and in some measure a connected question, is that of spontaneous generation of living organisms. Many accomplished scientific men, physicians, and microscopists have entered into these investigations. Prof. Wyman, of Cambridge, and Pasteur and Pouchet, of France, have studied the subject of spontaneous generation. In their experiments they depend on the purity of distilled water, that is, its freedom from organic germs. Dr. Angus Smith, of Manchester, England, has collected the organic matter of the air, for the purpose of searching for germs. The contents of the air were collected in a large bottle, and washed with a small quantity of distilled water. The microscopic investigation was done by Mr. Dancer of Manchester, a well-known expert at microscopy, who reported a vast number of organic forms as thus collected. Metcalf Johnson has published in the *Monthly Microscopical Journal* several papers on "what he has found in the air."

All these investigations depend finally on the absence from the water of organic matter or germs.

Having undertaken within a few months to ascertain the organic contents of the air in Boston, I commenced by drawing a large quantity of air through a small quantity of filtered water, which, when examined with the microscope, appeared microscopically pure. I found large quantities of organic matter, a very few organic *forms*, and a great many very minute bodies, which, may be, were fragments of organic or inorganic matter, or monads, or germs, according to the fancy or theory of the observer. Not feeling quite satisfied as to the pu-

rity of the water used, I evaporated a drop of it on glass. Placing that under the microscope, I beheld at once a collection of the same organic matter and minute bodies that I first supposed I had obtained from the air. This put an end to the use of filtered water. I then obtained from a friend a sample of carefully distilled water, which had been, however, distilled a month. Testing that in the same way, I found the same things more abundant even than in the filtered water. Another sample, also distilled some weeks, but kept with great care by Prof. J. Bacon of this city, gave precisely the same results. A third trial — on a sample freshly distilled, expressly for me, from a perfect apparatus, entirely copper and tin, the steam nowhere coming in contact with glass — also gave organic fragments, looking like degenerated or decaying epithelial cells, as before, and vast numbers of the minute bodies, $\frac{1}{50000}$ to $\frac{1}{10000}$ of an inch in diameter. Although nothing could be seen by the eye in the water in a bottle (a bottle has considerable magnifying power on its fluid contents), yet there was sufficient deposit from one drop on the glass slide to be distinctly visible.

These results indicate that no reliance is to be placed on any conclusions or inferences to be drawn from any experiments yet reported, as to the existence of organic "germs" in the atmosphere, where the medium of collection or examination was water; and when glycerine is used, we cannot follow any development of the supposed germs to ascertain their nature. The plan proposed by Dr. R. L. Maddox, in the June number of the monthly *Microscopical Journal*, seems to be the most reliable, but even that is not absolutely certain. The question now is, Is it possible to obtain in any manner absolutely (optically — not chemically) pure water?

C. STODDER.

BOSTON, *July*, 1870.

THE "BEAD" ON LIQUIDS.

A DRUGGIST in Sheffield, Mass., writes as follows: —

"It might interest many readers of the JOURNAL OF CHEMISTRY if you would give in it your views of the cause of the phenomenon called 'the bead' in alcoholic liquors. The popular idea, that it is an indication of the alcoholic strength of the fluid, is completely disproved by the fact that common alcohol (90%) shows very little of it, and pure Cologne spirit none at all. I have cursorily examined a number of tinctures, etc., in the hope of tracing some general principle that would account for it: The preparations which showed it most strikingly were tinctures of Capsicum, Cubeb, Lupulin, Senna and Jalap, and Tolu; and also Cologne, made after Parrish's recipe No. 1.

It was marked, though in somewhat less degree, in tinctures of Aloes, Calumba, Cardamom (simple and compound), Hyoscyamus, Kino, Squills, and Valerian.

It was distinct, though not striking, in tinctures of Catechu, Cinchona (*not compound*), Cinnamon, Benzoin Co., Belladonna, Aconite, etc., Krameria, Assafœtida, Aloes, and Myrrh, and Spts. Lavender Co."

Remarks. — We suppose that what is called "bead" or "froth" upon liquids, results from the intermixture of air with the liquid. The "bead" is a minute air-bubble, and is most easily formed by agitating liquids which are of a mucilaginous, soapy, or oily nature. Alcoholic liquors which hold large proportions of water afford the froth readily. Rum made from molasses gives more froth than diluted alcohol of equal strength. The "bead" is an uncertain guide in indicating the alcoholic strength of liquids.

THE MEDICAL MAGAZINES FOR JULY.

WE hoped, as we intimated in our last, to give in this number a summary of the leading articles in our medical exchanges for July, but we have received only a few of them before going to press, and those not in season for a thorough examination.

The New York Medical Journal has elaborate papers on Intra-uterine Medication, by Prof. Peaslee; on the Nature and Treatment of Croup, by Dr. J. H. Hobart Burge; on the Origin of Diabetes, with new experiments regarding the Glycogenic Function of the Liver, by Prof. Lusk; and on the Physiological Effects and Therapeutic Uses of the Bromides, by Dr. Z. C. McElroy.

The American Practitioner, which is one of the handsomest as well as one of the best of our exchanges, has important articles on the Use of Electricity in Medicine, by Prof. Holland; on the Treatment of Pneumonia, by Dr. J. Hale; on the Mineral Springs of Kentucky, by Prof. L. P. Yandell, Jr.; and on Immovable Apparatus in Fractures of the Lower Extremity, by Prof. D. W. Yandell.

The Chicago Medical Journal has papers on Clinical Experiences in Private Practice, by Dr. Z. C. McElroy; on Nasal Catarrh, by Dr. M. F. Potter; a continuation of the translation of Legros and Onimus upon the Influence of the Electric Current on the Nervous System; with much other fresh and valuable matter. It reprints in full Dr. Holmes's poem of "Rip Van Winkle, M. D.," the mingled fun and philosophy of which will be heartily appreciated by our Western friends.

The Northwestern Medical and Surgical Journal is a new monthly, published at St. Paul, Minnesota, by the Editor, Dr. Alexander J. Stone. The first number is very promising.

The Indiana Journal of Medicine has reached its third number, in which we find an excellent paper on the Use of Hydrate of Chloral in Cerebro-spinal Meningitis, by Dr. A. Patton. The Abstracts from Foreign Journals, by the Associate Editor, Dr. G. Bell, are a good feature of this young monthly.

CANCERS CARBONIZED. — Prof. Scott, of New York, has discovered a new method of treating cancer, which promises to supersede the empirical and unsatisfactory remedies hitherto employed. He applies to the surface of the sore the chloride of chromium incorporated with stramonium ointment. This preparation, in the course of a few hours, converts the tumor into perfect carbon, and it crumbles away. Specimens of cancers thus carbonized were shown at a meeting of physicians at the N. Y. Medical University, and were examined with much interest. They had the appearance of charcoal, and were easily pulverized between the fingers. The remedy causes little or no pain, and is not poisonous. It is not stated whether it is the protochloride or the sesquichloride of chromium which is used. It is the latter which is usually meant when the "chloride" is spoken of. As the report of Prof. Scott's paper in which he gives an account of his discovery speaks of this chloride as "a new salt" of chromium, it may be that it is neither of those just mentioned; for they are by no means "new" to chemists.

BOSTON MEDICAL AND SURGICAL JOURNAL. — We congratulate the publishers and the readers of the B. M. and S. Journal, that a change has been made in its editorial conduct. Dr. Parks has retired, and is succeeded by Dr. Francis H. Brown of this city, a gentleman of rare culture and scientific attainments, a physician who brings to the editorial chair much professional experience, and a candid, discriminating mind. He has the efficient aid of Dr. H. H. A. Beach, and in charge of these two accomplished gentlemen we predict for the Journal a decided increase in patronage and influence.

FOREIGN NOTES.

M. Viennet, the French author, has sent the following note to Dr. Gannal, the inventor of a new process of embalming: "Your prospectuses annoy me. During the last two days I have received no less than four of them, — one, as peer of France; a second, as member of the Academy; a third, as member of the Legion of Honor; a fourth, as a taxpayer. You doubtless reckoned on having four corpses to embalm. There will be only one, however; and that I will take good care to preserve from your tender mercies, having this day inserted a clause in my will to deprive you of the possibility of this little benefit. Thanks for so many kind attentions."

Alphonse Karr has happily defined dyspepsia as "the remorse of a guilty stomach."

A dentist now occupies the room where Balzac was born, and an English admirer of the great French author recently had two sound teeth drawn there as a souvenir of his visit.

M. Decaisne has made a report to the French Academy on the influence of the sewing-machine upon the health of women using it. He considers that its ill effects have been greatly exaggerated, and that the health of those who work with it averages as good as that of needle-women.

M. Sauer, of Berlin, after experimenting with all kinds of anæsthetics, comes to the conclusion that the very best is a mixture of protoxide of nitrogen, chloroform, and atmospheric air. He believes this mixture to be free from the dangers that attend the use of either chloroform or the protoxide alone. The proportions he uses are as follows: chloroform, six grammes; atmospheric air, three quarters of a litre; protoxide of nitrogen, sixteen litres.

In Europe, diphtheria and croup have been successfully treated with a wash of permanganate of potassa, one scruple of which is dissolved in six ounces of water.

The *Union Médicale* reports that a severe case of eclampsia was cured by bromide of potassium. One drachm of the salt was dissolved in four ounces of water, and a teaspoonful given every fifteen minutes.

Dr. Matthews Duncan is spoken of as the successor of Sir James Y. Simpson in the obstetrical chair of the University of Edinburgh. There is a movement on foot for placing a monument to the latter in Westminster Abbey.

HAIR DYES.

WITHIN the past year or two the public have been warned through your JOURNAL, and also many secular papers, against the use of preparations for the hair containing lead, and many physicians whose attention has been directed to the matter have warned their patients against it. Still the sale and use of these deleterious compounds continue as great as ever. Among all this class of nostrums I must rank "Hall's" preparation as one of the worst. I have had several, not only incipient, but fully developed cases of lead poisoning, which could only be accounted for by the use of this article. One of my patients is a lady who for many years has suffered from general nervous diseases, and her husband, who is an intelligent druggist, long ago suspected that the hair dressing she used (Hall's) was the cause of the peculiar benumbed feeling of the scalp, with derangement of the muscular power of the hands and arms, and caused her to cease from using it for some time, but for a few months past she has again used it. I found her in such a peculiar condition that I was led to suspect lead poison, and questioning brought out the fact. Is there no way by which the manufacture and sale of such well-known poisons can be prevented?

I recommend to those needing a preparation for the hair, the following, which is used by the ladies of my own family, and found to be all they require: Castor oil 4 drachms, Glycerine 2 drachms, Aqua Ammonia 1 drachm, good Cologne 6 oz. Mix the oil with the cologne first, shaking it well, and then add the rest.

Where there is evident weakness in the hair-bulbs, use the following: Castor oil 2 drachms, Glycerine 4 drachms, Tinct. Cantharis 1 drachm, Cologne 6 oz. Neither of these is found to injure the hair, and they keep it soft, and the scalp clean.

BENJAMIN WOODWARD, M. D.

WYANDOTTE, KANSAS.

SACHET POWDERS.

THE *Druggist's Circular* publishes the following in reply to inquiries for first-rate articles of the kind: —

Frangipanni Powder.

Powdered violet roots,	3 pounds,
" sandal-wood,	$\frac{1}{4}$ pound,
Orange oil,	1 drachm,
Rose oil,	1 "
Oil of sandal-wood,	1 "
Pulverized musk,	1 ounce.
" civet,	2 drachms.

Heliotrope Powder.

Pulverized violet roots,	2 pounds,
" rose leaves,	1 pound,
" Tonka beans,	$\frac{1}{2}$ "
" vanilla,	$\frac{1}{4}$ "
Granulated musk,	2 drachms,
Oil of bitter almonds,	5 drops.

Patchouli Powder.

Pulverized patchouli leaves,	1 pound,
Patchouli oil,	1 scruple.

Rose Powder.

Pulverized rose leaves,	1 pound,
" sandal-wood,	$\frac{1}{2}$ "
Rose oil,	2 drachms.

Verbena Powder.

Dried and pulverized lemon peels,	1 pound,
Caraway seeds,	$\frac{1}{4}$ "
Oil of lemon peels,	4 drachms,
Oil of bergamot,	1 ounce.

GENTIAN IN DYSPEPSIA.

DR. CHARLES CARTER, of Philadelphia, in an article contributed to the *Indiana Journal of Medicine*, states that he has found the following combinations of Gentian very serviceable in numerous cases of dyspepsia: —

℞

Gentian Root (broken), six drachms.

Wild Cherry Bark, one half ounce.

Quassia, two drachms.

Infuse in two pints of hot water.

Dose, a wineglassful before meals.

℞

Sub-Nit. Bismuth, one drachm.

Calc. Carb. Precip., three drachms.

Fl'd Ext. Gentian, one half ounce.

Aqua Cinnamon, three and one half ounces.

Dose, a teaspoonful before and after each meal.

"This latter," says Dr. Carter, "is not a very elegant mixture, for the powders, which must be given suspended in the liquid, precipitate. The mixture, therefore, requires to be well shaken before using. It is, however, very effective. I have recently administered it in a very severe and protracted case of dyspepsia, with complete relief of all the symptoms. The patient was under its use for about eight weeks. When he applied to me he was affected in the following manner: Loss of appetite, severe and frequent attacks of colic, diarrhœa, want of sleep, great emaciation, cough, want of ambition, and a confused and disturbed state of the mind. The emaciation was so marked that I was led to suspect phthisis, but a careful examination of the chest did not reveal any evidence. The patient informed me that for the two weeks preceding the last time I saw him, he had gained in weight seven pounds."

A CHILD BORN WITH A CHIGNON. — Dr. J. M. Marchant of Warren, R. I., writes as follows concerning a curious freak of nature that lately came under his observation: —

"A male child was recently born in this town, having upon his head what is rather a useless appendage to one of his sex. Covering that part of the head usually occupied by the *chignon*, is a thick curly mass of hair some three inches in length, and dark brown like the mother's, while that upon the rest of the head is short, thin, and very light. The father's hair is red."

A CAT INFIRMARY.

A RICH and eccentric business man, of Columbus, Ohio, has recently made a will, which disinherits all the natural heirs of the maker of it, and devises the entire property in trust for the establishment of an *infirmary for cats.* It provides areas for that sweet amatory converse so dear to the feline heart, and ratholes of the most ravishing nature to be kept well stocked. The most ingenious contrivances are provided for securing to the rat a chance for escape, so that the cats may not lose the pleasure of the chase by finding their prey come too easily. High walls are to be built, with gentle sloping roofs, for the moonlight promenade and other nocturnal amusements of the cats. The trustees are directed to select the grounds for this novel infirmary in the most populous part of some great American city, and the devisees are to be protected, by a competent force of nurses, from the ravages of men and dogs. No person of the male sex is ever to be admitted within the walls, and no female who has children or is under thirty years of age.

The last provision of the will is more ridiculous than the previous ones. Says the devisor: "I have always been taught to believe that everything in and about man was intended to be useful, and that it was man's duty, as lord of animals, to protect all the lesser species, even as God protects and watches over him. For these two combined reasons — first, that my body, even after death, may continue to be made useful; and secondly, that it may be made instrumental, as far as possible, in furnishing a substitute for the protection of the bodies of my dear friends, the cats — I do hereby devise and bequeath the intestines of my body to be made up into fiddle-strings, the proceeds to be devoted to the purchase of an accordeon, which shall be played in the auditorium of the cat infirmary by one of the regular nurses, to be selected for that purpose exclusively — the playing to be kept up for ever and ever, without cessation, day or night, in order that the cats may have the privilege of always hearing and enjoying that instrument which is the nearest approach to their natural voice." — *The Quart. Jour. of Psychol. Medicine.*

A NEW REMEDY FOR ASTHMA.

THE following extract from a letter lately received makes mention of an addition to the *materia medica:* "Dr. P., of Lawrenceburg, Indiana, some forty years ago related to me, among other incidents of early frontier life on the Ohio, his experience of a novel remedy involuntarily taken. The doctor had from childhood been a martyr to asthma; it was the rock ahead for which he was continually on the lookout. One day — it must now be near seventy years ago — in travelling the rounds of a country practice, and while yet at a distance from any shelter, a storm of rain burst suddenly upon him. He rode at full speed for the nearest cabin, distant some miles, and reaching there, drenched to the skin and gasping for breath, he dismounted and made the best of his way to the door. As he entered he met the inmates of the cabin rushing pell-mell out in the rain, holding their noses, and giving expression in every possible way to the most extreme disgust. He was not long in discovering the cause for their actions. The dogs had chased a polecat under the floor, and the whole atmosphere was loaded with its horrible effluvium. It was a choice between polecat and asthma, and Dr. P. chose the former and remained in the house. To his surprise the constriction of his chest began to disappear with the first inhalation, and in ten minutes he was free from every trace of the paroxysm. As soon as he could do so, he procured the musk-bag of one of the animals, and prepared an alcoholic tincture. The scent of this never failed to avert promptly a paroxysm of the disease, and ultimately the remedy, or time, or both combined, effected a permanent cure. He assured me also that he had successfully used it in cases similar to his own. Belonging, as it does, to the same class with musk and castor, but infinitely more active and efficient, if its odor be taken as a criterion of power, it may prove a valuable antispasmodic. I have seen cases of hysteria upon which, from a safe distance, I should have been delighted to witness a trial of its powers." — *Amer. Practitioner.*

A PHYSICIAN ON THE STAND.

THE standard legal dictionaries in use may be searched in vain for more accurate definitions of legal terms than those recently given by a physician in Pulaski, Tennessee, as reported to us by a leading member of the bar of that place. Mr. B. and a Mr. L., opposing counsel in a pending case, were engaged in taking depositions to be used on the trial of the cause. The question as to a certain woman's soundness of mind being in controversy, a physician was called as a medical expert, and during his examination the following dialogue took place: —

Question. — Do you think this lady is of sound mind?

Answer. — No, sir; I do not.

Ques. — Does she know the difference between a "power of attorney" and an "absolute conveyance?"

Ans. — No, sir; of course she don't, and there are very few women who do.

Ques. — Do you know the difference?

Ans. — Yes, sir; of course I do; do you suppose I am an ignoramus?

Ques. — Well, sir, will you be kind enough to tell us the difference?

Ans. — Well — well, a "power of attorney" is the strength of mind of any particular lawyer; and an "absolute conveyance" is a hack, or omnibus, or railroad car, or something of the sort. — *Bench and Bar.*

"CHOCK FULL OF LIGHTNING!"

A CORRESPONDENT on the wing, in one of our Western States, gives the following as an illustration of the ignorance of some practitioners in the West. He says: "I was invited home to dine one day by a regular M. D., a graduate of a Cincinnati college, who is doing a large business, and is worth perhaps $10,000. In the course of our conversation he mentioned the fact of his having lately been called to see a woman who had been struck by lightning. After stating his treatment in the case, he said that the results had not been satisfactory, and that if called to see a similar case again, he would pursue a different course. I asked him what that would be. Said he, 'I would wrap her in a wet sheet to draw the lightning out of her! Why,' said he, 'she's chock full of lightning yet; you can see it run down her legs and arms every now and then, and she can feel it shootin' through her body. Now if I had wrapped her up in a wet sheet, the lightning would all have been drawn out, and she would been got well sooner.' In answer to all my explanations of the laws of electricity, his reply was, that 'he didn't keer for equilibriums or anything else; *he* knew she was chock full of lightning anyhow.' This case is true in every particular, and the man has a diploma from a regular medical school, and *one* of the first in this country." — *Med. and Surg. Rep.*

Familiar Science.

LEATHER IN THE TEA-CUP.

[E]VERYBODY knows, we presume, that leather [is m]ade by steeping hides in an infusion of certain [veg]etable substances which contain a compound [cal]led *tannin.* The cheapest source of this tan[nin] principle is oak bark, but it is found in [gre]ater or less quantity in many other plants, as [th]e grape, the hop, coffee, tea, etc., and from [th]e it can be dissolved out with water. The [skins] of animals consist mainly of albumen [and] gelatine; indeed these substances are abun[dant] in all animal matter. In the blood and in [mil]k the albumen is merely suspended, as it [wer]e, in the water which constitutes by far the [large]r portion of these fluids. Tannin and al[bume]n have a remarkable affinity for each [ot]h[er], and unite as soon as they are brought in [conta]ct. The result of their union is the in[solub]le, tough material which gives leather its [distin]ctive character. When the hide is steeped [in th]e infusion of oak bark, the albumen of the [form]er thus combines with the tannin of the lat[ter, a]nd the loose, soft tissue of the skin is con[verte]d into hard, tough leather.

[N]ow when we pour milk into a cup of tea or [coff]ee, a similar chemical combination occurs. [The] albumen of the milk and the tannin of the [tea i]nstantly unite, and form leather — or minute [part]s of the very same compound which is pro[duce]d in the texture of the tanned hide, and [whic]h, as we have said, makes it *leather* as dis[tingu]ished from the original skin.

[T]annin has a peculiar taste which is tech[nical]ly called *astringent.* We can detect this [fla]v[or] in chewing the skin of a grape or the [see]ds of a raisin, and in coffee and tea before [the m]ilk is added. One of the main objects in [addi]ng the milk is to mitigate this astringent taste, [and t]hus enable us to enjoy more perfectly the [fine] flavor of the tea or coffee. Some people [pref]er the full astringency of the tannin, unmodi[fied b]y the milk, and so take the beverage with[out th]e leather; but with most of us the tea-cup [regul]arly becomes a miniature tannery. In the [cours]e of a year, a tea-drinker of average habits [will h]ave imbibed leather enough to make a pair [of sh]oes, if it could be put into the proper [shape] for the purpose.

[It] will be found, upon experiment, that a [small] quantity of milk produces a much greater [opaci]ty with tea than with water which has been [tinged] of the same color as the tea by the addi[tion] of burnt sugar. Of course, it is the minute [partic]les of leather floating in the liquid in the [form]er case, that causes the difference. If we [pour] the tea into a glass and hold it up to the [li]ght while the milk is dropped in slowly, the [chem]ical action will be very clearly seen. If [we u]se a very strong infusion of tea, and put in [a con]siderable quantity of milk, we can get a distinct precipitate of the *tannate of albumen,* or solid leather, by letting it stand for an hour or more.

We may add that the presence of tannin in tea is shown by the action of the liquid upon iron. Tannin, in most of its forms, unites instantaneously with this metal to form *ink;* and a drop of tea upon a knife-blade produces that familiar black compound at once. Singularly enough, the tannin in coffee does not unite with iron in this way, so that other tests are necessary to detect it.

A RAILROAD TO THE CLOUDS.

We have recently been on an expedition to the clouds, taking railroad direct to that misty region. But, as is usually the case when we attain to extraordinary results by any human art or invention, our ambition is only excited to reach further, or mount higher. We are now waiting for some one to construct a railroad to the moon, and when such a line of communication is opened we shall engage passage without investigating or questioning the *safety* of the device. Any one who has been above the clouds by rail, and reached that altitude by direct, almost perpendicular ascent, is prepared to go in any direction where audacious man may place his iron bars and blow his steam whistle.

The railway from the base to the summit of Mount Washington in New Hampshire is a marvel of modern engineering skill and daring. The road is constructed up the face of the huge rock, the grade being much of the way "very heavy," or equal to one foot ascent in three. This gives an upward inclination about equivalent to the roofs of our Gothic edifices, and when the engine is up the incline and stationary, it seems at a little distance to be clinging to the rock in a most fearful position. We may well imagine it to be some strange live animal, which has crawled up to a dangerous point on the cliff, and is there fixed, not daring to go forward or backward, for fear of a tumble. The track is laid to the very summit of the mountain, and the train enters and often passes above the clouds, which usually rest upon the lofty peak.

This railway is a great steam elevator of peculiar or novel construction, and it accomplishes an end which has never been reached before in the history of engineering. It requires about one and a half hours to "go up," including three stops to "take in water." It is estimated that the train would come down in *three minutes* if left to itself. We hope it will never be "left to itself," and that its trucks and cogs will never "play false" when they are pressed upon by a human freight. A train of passengers left to go down that fearful incline would be instantly torn or crushed to a jelly. But we are asked, Is it *safe?* We have perhaps given a satisfactory practical expression of our views upon this point, by placing ourself and family in charge of the engineer, and making the ascent. If we were asked if we would make a second excursion, some hesitation would be manifested before replying, yes; and yet abundant and efficient safeguards are provided against accident, and we do not well see how one *can* occur.

THE SEA AND THE LAND.

"The troubled sea that cannot rest" is an active and incessant worker. In calm and in storm it is alike busy, steadily carrying forward a thousand mighty labors. When the poet, in that famous apostrophe to the ocean which is familiar to every schoolboy, said, —

> "Thy shores are empires changed in all save thee,"

he merely put into verse the popular impression that the shores of the sea remain unchanged from age to age. But geology tells a different story. It teaches us that the boundary between the ocean and the land is ever changing. A map of the world at one geological epoch will not serve to represent its appearance at an earlier or a later period in its history. The continents are no more fixed and immovable than the waters that surround them. Their surface is rising and falling continually in undulations which, if slower in their motion than the waves of the sea, are on an immensely grander scale. We talk of "mountain billows," but the mountains themselves are nothing more than the billows of the great tide which in the lapse of geological ages sweeps across the continents. The "everlasting hills" are not eternal, but are the ripples of this ceaseless rise and fall to which the solid earth is subject.

Even within historic times, and in some cases within the limits of a single century, this undulation of the land has been detected and measured. There are localities where the changes thus effected in the geography of large districts are very striking. M. Quenault, in a little book recently published with the title "Les Mouvements de la Mer" (The Movements of the Sea), gives many interesting facts, gathered from old records as well as from his own observation, respecting the sinking of the land and the encroachments of the sea on the coasts of Brittany, Normandy, and other places on the northern and western borders of France. Thus, in the Gulf of Cordouan, at the mouth of the Gironde, the sea has advanced 730 metres (2,395 feet), within twenty-eight years; the buildings on the Pointe de Grave have often been destroyed and rebuilt, and the light-house is now removed, for the third time, more inland. The sea flows more than ten metres deep over what a short time since was a sandy beach.

The popular legends of Brittany lead one to think that many places near the coast, and now immersed, were formerly above the level of the sea. With their passion for the marvelous, the country people refer these facts to supernatural agency, where the devil plays a prominent part.

The Bay of Douarnenez, where at high water the depth is considerable, is the site of the once flourishing city of Ys. At the south side, when the tide is low, are distinguished clearly, five or six metres under water, Druidical remains, altars, portions of walls, and ruins of various monuments. On the opposite side, near Cape Chevre, they are also to be found, though not so easily seen and not so numerous. The fishermen there believe all the reefs and rocks in the bay to be portions of the ruins. In the sixteenth century, when the water in the bay was not so deep as now, Canon Moreau was able to follow the lines of a vast inclosure of masonry, and above the sand, in the shallower places, he discovered funeral urns, stone sarcophagi, etc. The traveller Comby also adds, that after a storm which excavated and scooped out portions of the sands, one could perceive traces of elm trees, disposed with a regularity which shows that a plantation existed at this spot.

Submerged forests have been found on the coasts of Brittany, and particularly in Finisterre, in the neighborhood of Morlaix. There are historical documents to prove that at the Bay of Mont Saint-Michel the coast has been submerged since the period of Roman rule. Rouault, Curé de Saint-Pari, says: "About the year 400 there was in Lower Normandy, towards the west, a large forest named Scicy, extending from the rocks of Chausey to the Mont de Tomba," now Mont Saint-Michel. In the twelfth century the troubadour Guillaume de Saint-Pari referred to this submerged forest in a quaint bit of old French, which may be freely translated thus:—

"Not far from Avranches, on Brittany's shore,
Quokelonde forest spread out of yore;
But that famous stretch of fertile land
Is hidden now by the sea and the sand;
No more will its venison grace the dish —
The ancient forest yields nought but fish."

This forest of Scicy was said to have been full of wild beasts, and peopled by half-savage natives, to whom succeeded, in Christian times, a number of anchorites who sought retirement there, far from the tumult of the world. The parishes of St. Louis, Mauny, and La Feuillette have disappeared beneath the waves since the thirteenth century. A story is told of a priest of the diocese of Dol, that having, in 1685, learned by tradition that there was formerly, in the place then (and now) occupied by the sea, a parish named St. Louis, he informed the Court of Rome that this living was vacant "*per obitum*." Upon this they consulted the registers and found actually that there had been presentations to this living by former Popes. A priest of Basse-Bretagne was therefore appointed, and he departed at once to take possession. But on arriving in sight of Mont Saint-Michel, what was his surprise when he was shown, on the sands and in the sea, the place where was formerly situated his pretended parish.

There is every reason to believe that the whole of the Channel Islands were, at one time, part of the mainland of France, and there is positive proof of the island of Jersey having been so. There are certain existing manuscripts belonging to the monastery of Mont Saint-Michel which tell us that, in the sixth century, the district of Jersey was separated from the mainland of Coutances by only a narrow rivulet, bridged by a single plank, which the inhabitants were bound to keep in repair for the Archdeacon of the mother church to pass over on his periodical visitations. In the register of the taxes of the island, there is an entry referring to rents received from various persons for the privilege of allowing pigs to feed on the acorns in the forest of St. Ouen — now the bay of that name. M. Quenault gives an exceedingly interesting map of this part of the French coast — a *fac-simile* of a chart copied in the year 1406 from one of a much older date. This map shows the coast line from Cape Finisterre down to St. Malo to have been, at that time, from six to twelve miles farther west than at present. The island of Jersey is part of a peninsula, ten or twelve miles wide, stretching out from the French coast to a point some three or four miles west of that island as it exists at present. Guernsey also is shown to have then been considerably larger than the Isle of Man now is. Throughout the whole area of this departed coast are depicted the positions of some score of places where evidences of the existence of submerged forests have been discovered.

The sinking of this region which has taken place within the period of history has occurred only between the parallels of 10° S. and 55° N. latitude. North of this, it is gradually becoming more and more elevated.

M. Quenault concludes, with regard to the depression of the land: "One gathers from all these evidences, that the movement, since the eighth century, has been about two metres a century. If it continues at the same rate for ten centuries more, the peninsula of Cotentin will be an island, and all the ports of La Manche will be destroyed. Some centuries later and Paris will be a sea-port, waiting only to be submerged in a score of centuries. Thus in a period less than half as long as that during which the pyramids of Egypt have braved the ravages of time, Paris itself, if it is not burned down during one of the revolutions of its inhabitants, — as amiable and *spirituel* as they are inconsistent, — Paris will probably be engulfed in the Atlantic, a master before whom the intractable Parisian must haul down his flag. Let him take warning!"

HAILSTONES.

How are they formed in such hot weather? This seems to be a mystery to most. The *Boston Journal* of June 24th, speaking of the late hailstorm says: "It is a curious fact that hailstones generally do not fall with the usual velocity of rain;" and then proceeds to give different theories to account for this fact. "One theory is, that the clouds from which they come have a considerably lower altitude than ordinary rain clouds. Another suggestion is that made by the late Prof. Olmsted, that the hailstone, when it starts downward, is but a nucleus of snow, and that it congeals and accumulates layers as it falls, which process retards its velocity."

The true reasons why hailstones do not fall so rapidly as rain drops of the same weight, are, 1st, that ice is specifically lighter than water; and 2dly, that rain usually falls in round, smooth globules, the most compact and solid form, while hailstones are often rough and irregular in their forms, causing greater resistance from the air. And besides, both rain and hail usually attain a uniform velocity respectively, long before reaching the earth, like shot falling from a great height. The resistance of the air soon counterbala their weight.

Most of the books on meteorology state tha really satisfactory theory of the formation of h stones has been devised; but it seems to writer, that this phenomenon is susceptible of v satisfactory explanation, if not absolute scien demonstration. He will endeavor to give his vi as briefly as possible, and at the same time to m the subject intelligible to the ordinary readers the JOURNAL.

It should be remembered that the atmospher an elastic fluid, eight hundred times lighter t water, yet of great weight, pressing everywh upon the surface of the earth about fifteen pou to the square inch, but, as we rise above the level, decreasing in density with great uniformity that at a height of about three miles it is only half this weight, or $7\frac{1}{2}$ lbs.; at *six* miles, one fou or $3\frac{3}{4}$ lbs.; at nine miles, one eighth, or $1\frac{7}{8}$ lbs. fifteen miles, $\frac{1}{32}$ or $7\frac{1}{2}$ ounces, etc. The ai principally composed of oxygen and nitrogen ga in the proportions of 21 to 79 parts by weight, about one thousandth part carbonic acid gas. H we have the material for the winds, as also medium for watery vapor, from which falls the d and out of which the clouds are formed.

Heat causes this vapor to arise from sea land, — from whatever contains moisture. This visible process is going on continually, as soon one storm is over, preparing for another, till atmosphere is sometimes completely saturated w it, while yet it may remain perfectly clear — n cloud to be seen.

Now for the process by which this invis vapor, diffused through the lower strata of atmosphere, becomes *cloud*, yielding rain, snow, hail. *Four* well established laws will prepare u elucidate the phenomena. *First*. In ascen from the earth every one hundred yards (n exactly, 352 feet) the thermometer falls *one* deg 200 yards 2°; 500 yards 5°; 1,000 yards 10°; 6, yards 60°. Above this, the law slightly varies.

The *second* law relates to what is called the *point*, as discovered by the illustrious Dalton. is the point of temperature where dew or cl first *begins* to form. As heat changes water vapor, so the abstraction of that heat restore to the form of *cloud*, or visible watery partic *Vapor* is invisible; as it becomes visible, it called *cloud*. By ascertaining the *dew point* at time, we may discover the entire amount of va in the atmosphere at that time. It has been fou that if the dew point be at 32°, just $\frac{1}{240}$ of the is vapor, so that if it should then all fall in rai would amount to 1.72 inches. When the dew p is at 52° (20° above 32°) just $\frac{1}{120}$ is vapor, or in.; when at 73° (21° above last) just $\frac{1}{60}$ is va or 6.91 in.; when at 80° (highest ascertained) $\frac{1}{48}$ is vapor, or 8.64 in.; that is, the vapor dou for about every 20° above the freezing point.

The dew point may be easily ascertained any time, by the aid of a thermometer and tumblers or pitchers. Fill one tumbler or pit partly full of hot water, the other with cold. N the thermometer as it stands in the air to be tes (say 72°). Now put the thermometer into the water, and pour in slowly from the cold, noti carefully when *dew* first begins to appear on outer surface of the glass; then take the readin the thermometer inside the glass (say 62°) and have the dew point, 62°. Take the differe (72° — 62° = 10°), and make careful note of for future use.

We are now prepared for the *third* law. W dense air is rarefied, or made thin, it is ther *cooled*. Exhaust one half the air from a recei and a thermometer inside it *falls*. The receive still full as before, though the air is only one

dense. The heat is consequently more widely fused. This principle explains why it is colder, you ascend into the upper regions of the atsphere, the air becoming more thin.

Now, as shown by our second law, if we could e that dense air at 72°, with the dew point at °, and carry it up 1,000 yards, it must expand, l so be cooled down those 10° to the dew point, l *cloud* would there begin to appear. All this evident; but how shall this dense air be thus vated?

If we build a fire in an open fire-place, the air heated above and rises, as indicated by the ascent the smoke. There is a tendency to a vacuum at fire, but the exterior air rushes toward it to tore the equilibrium, while the current continues ward over the fire. The same is true when re is kindled in an open field on a calm day. e heated air rises over the fire, as in the mney, while the air flows toward it from every and then *up*; it cannot accumulate. If the becomes powerful, the calm is destroyed; the d seems to start from all sides toward the fire, l there goes up, often carrying up large cinders, l if sufficiently powerful, this upward current y reach the dew point, and then *cloud* must in to form. If the fire be on a hill or mountain, Vesuvius, this greatly aids the process. Thus an ption of Vesuvius often causes torrents of rain.

And it is on these principles, doubtless, that we e the ordinary summer shower, with lightning thunder. It comes in the warmest weather; sun acts as a mighty fire, warming the surface he earth. As this becomes heated, the atmosre coming in contact with it also becomes heated rises, producing that glimmer we often notice a warm day, as also over a hot stove; but the qualities of the land probably aid this ascent, sing the heated air to glide up the sides of a more in a mass, and then reaching the summit n all sides, it pierces the cooler atmosphere, and s up an invisible current (like smoke) till it hes the dew point, and then what we often call hunder-head or summer-cloud, more properly a *ulus*, begins to form. If a brisk horizontal wind lowing, it may soon break away without rain, another and another start, and so over the le region. These clouds are thus formed, much we see a *steam-cloud* rising from a locomotive, ecially in cold weather; only this is soon dissipated he atmosphere. So the cumulus clouds, broken y from their base, begin to descend into warmer ons, and soon disappear slowly, as may be seen careful observation. But in order to complete demonstration, we must introduce a

Fourth law, or principle, that of *latent heat*. This hat form of heat which becomes *concealed* in ies, in their change from a solid to a liquid, or id to an aeriform state. In melting ice, the mometer stands at 32° in the mass till all is ted, when it rapidly rises to the boiling point, 2°, where again it stands till all is converted into m, when if confined its temperature again rises. heat applied during the *change* of state bes *latent*, as indicated by the thermometer's rening stationary.

A cubic foot of water (about 30 qts.) converted steam or vapor, under the ordinary pressure of atmosphere, measures about seventeen hundred c feet, and it requires a large amount of heat produce this change. But changing seventeen dred cubic feet of vapor back into *one* of water, ores that heat; it is no longer *latent*, but bees manifest, affecting the thermometer and the es. The heat thus developed in a single ver has been estimated equal to that produced burning 30,000 tons of coal, — an almost inconable amount of heat, like that of an intense ace, or Vesuvius itself in eruption. The consequence of this remarkable development of heat, at the dew point, is to increase suddenly and powerfully the upward current, forming cloud with great rapidity in the higher and cooler regions, the current driving the cloud into drops of rain and throwing these upward with more or less force, till turning *outward* they descend on all sides, — and some through the centre, if the upward current be not too violent, — and thus we have the beautiful shower of rain. The drops in their ascent and descent move somewhat in the form of a sheaf of wheat, standing upright, each straw indicating the line of a rain drop.

Now for the *hailstones*. If the shower become very violent, as is most likely in the hottest weather, the upward current may send up the drops of rain *ten miles high*, into regions of intense cold (over 100° below zero), accumulating as they ascend into large irregular drops, freezing in their upward as well as downward course through such intense cold, into irregular solid ice, it may be of large size; the water driven by the violence of the current, going up in sheets, or irregular masses, rather than round smooth rain drops.

And here another fact should be stated. At an elevation of about three and a half miles, a current of air is always blowing from S. W. to N. E. — that is, from the equator toward the pole, to restore the equilibrium caused by an opposite current — so that, when a cloud, in a severe shower, rises into this current, the top of the cloud is blown over toward the N. E. side of the shower, and in case there is hail, it falls in a single glade on that side. If, however, it is more intense, the hail overcomes this more gentle upper current, so as to fall in two glades on the opposite sides of the shower, with a space between, in which there may be little or no hail.

Such is believed to be the true theory of the ordinary summer shower, and also of the hailstorm. Does it not rest on long established principles? The view is confirmed by many observations as well as by science. Every one has observed how the wind always blows *toward* the shower, while it is coming up, apparently in exact opposition, and then as the shower passes over, the wind turns and follows it, adding material, as it were from every side; also, how calm it often is, in the very midst of it, caused by the wind blowing toward its centre, and then upward. If more violent, it may not rain at all in the very centre, while it is pouring in torrents on every side. This, too, accounts for the *fall* of the *barometer*, the upward current taking off a part of the atmospheric pressure. Lightning and thunder arise from the sudden condensation of so much vapor to rain, which develops immense quantities of electricity. The appearance of the clouds, also, especially the cumuli, clearly indicates their formation, as before intimated.

The above *four laws* have been long since established, but the honor of combining them, to illustrate the formation of rain, snow, and hail, as above briefly described, belongs to the late Prof. Espy of Washington. It is passing strange, after his demonstrations of this theory, so simple and yet so beautiful and satisfactory, that there should still be so much "mist" enveloping the subject in the minds of even scientific men.

The theory may be extended with modifications, to storms, tornadoes and nearly all the phenomena of atmospheric changes, especially as connected with the deposition of vapor, in whatever form.

D. W.

An alloy of 50 parts of lead, 36 of tin, and 225 of cadulum, is recommended for stereotyping purposes as more feasible and at the same time harder than that usually made with bismuth.

NOTES ON FAMILIAR SCIENCE.

Speed of Electric Signals. — Professor Gould has found that the velocity of the electric waves through the Atlantic cables is from 7,000 to 8,000 miles per second, and depends somewhat upon whether the circuit is formed by the two cables or by one cable and the earth. Telegraph wires upon poles in the air conduct the electric waves with a velocity a little more than double this; and it is remarked, as a curious fact, that the rapidity of the transmission increases with the distance between the wire and the earth, or the height of the support. Wires buried in the earth likewise transmit slowly, like submarine cables. Wires placed upon poles but slightly elevated transmit signals with a velocity of 12,000 miles per second, while those at a considerable height give a velocity of 16,000 or 20,000 miles.

Cabbage-Tree of New Zealand. — It may not be generally known that the cabbage-tree (*Cordyline Australis*), which grows so abundantly in New Zealand, contains a very considerable proportion of saccharine matter. In former years, says *Applied Science*, the Maoris used, when on their fishing excursions up country, to hack down a few of these trees near their encampments, and after a day's exposure to sun and air, cut off quids, which they chewed with great gusto. Fifteen years ago a gentleman resident in Otago obtained a fair sample of sugar manufactured by the Maoris from the cabbage-tree, which he sent to London for inspection. The process for extracting the sugar, so far as we are aware, has not been divulged by the natives, and probably no individual European is conversant with the matter. It might, then, form an interesting subject for inquiry and dissertation how the process was accomplished, and how far could the tree be utilized for such a purpose. The cabbage-tree may be readily propagated from seed, and its growth is comparatively rapid. The whole tree is fibrous, and can be made into paper. It grows to a diameter of from 1 ft. to 3 ft., and height from 10 ft. to 20 ft., and is found chiefly in swampy situations, although it grows on hill-sides. The stem is thickly fibrous, and the leaves, which are long (ribbon-like) and about 2½ in. broad, contain a good deal of fibre.

The Cork Tree. — This tree is a species of oak growing abundantly in Spain, Portugal, and Italy. In Georgia the experiment of raising the tree from the acorn has been successfully tried, and we have no doubt there are many parts of our country where it could be acclimated. The barking is commenced when the tree is fifteen years old, and may be repeated every eight or ten years afterwards with no injury to the oak, which, in spite of this periodical flaying, lives to the age of a hundred and fifty years. In July and August, incisions are made around the tree, and down to the root; the pieces which detach easily are soaked in water, placed under heavy weights, dried before a fire, and stacked in bales for exportation.

The cork-cutters cut the sheets into narrow strips, and round them into shape with a sharp knife.

The Sulphur Beds of California. — Sulphur has been chiefly supplied from the sides of Mount Etna, in Sicily, but the works on the shore of Clear Lake, California, produce now 4 tons a day. This lake occupies the crater of an extinct volcano, and the evidences of volcanic action abound in the vicinity. The sulphur bed consists of a bank resembling ashes, containing numerous alkaline and sulphur springs with vent-holes, from which sulphurous fumes escape. Pure sulphur crystals deposited from the fumes surround these holes. The earth, containing about 50 per cent. of sulphur, is placed in an iron retort heated to a high temperature, so that the sulphur is driven off in fumes into a receiver, where it settles in a liquid form, and runs out into pine boxes 2 ft. long and 1 ft. square. The

lump sulphur is used chiefly for making powder and sulphuric acid, which last is employed in making blue-stone, giant-powder, nitric acid, and muriatic acid, and in refining gold and silver. The consumption of sulphuric, nitric, and muriatic acids on the Pacific coast amounts to 2,000,000 lbs., and the entire demand is supplied by home manufacture. Flowers of sulphur have also been produced at Clear Lake. The fumes passing off from the retort are in this case led into a large cool chamber, where they condense into a flaky snow-like condition.

HOUSEHOLD RECIPES.

Tomato Vinegar. — Take one bushel of ripe tomatoes, mash them in an open tub, add one quart of molasses, and thoroughly mix the whole together. Let the tub stand several days, frequently stirring the mixture. When a decided vinegar odor is given off, the juice should be strained from the pomace and put into casks. Vinegar thus made is equal to the best.

Cement for Pickle and Preserve Jars. — To two ounces of the best gum tragacanth, add six gills of cold water, and three grains of corrosive sublimate. Set in a warm place for two or three days, frequently stirring it to assist the solution. This will be found a very useful paste for labels, or for pasting paper over jars, holding pickles, preserves, fruits, etc., providing it does not come in contact with the condiment, to avoid which the jars should be first covered with paper or bladder, and then with the pasted paper.

To get rid of Flies. — The smoke of the dried leaves of a pumpkin burnt on a bright fire will cause flies to quit an apartment instantly, or it will kill them. Birds must be withdrawn before the operation, and persons should abstain from going into apartments immediately after, as the smoke causes headaches. The employment of laurel oil is also a preservative against flies, as they cannot bear the smell of it. In Belgium, butchers have long applied it, and with great success, to the doors and windows of their shops.

Cleaning Silver-Plated Articles. — White-metal articles, electro-plated with silver, should be cleaned with the greatest caution. The use of soap gives to the articles a leaden appearance. If tarnished, rub them with a little fine whiting, wet with water; then wash with clean, soft, warm water. Dry carefully, and polish with fine whiting on a piece of soft leather.

To wash Flannels without shrinking. — No woolen fabric should have soap rubbed on it, unless you wish to shrink it. Soak it in warm water half an hour; rub lightly when you rinse it out; then rub thoroughly in good hot suds; rinse it out, put in a tub and pour clean boiling water on it — the more the better; let it stand till cool enough to be rinsed out by hand.

To make old Kid Gloves new. — Make a thick mucilage by boiling a handful of flaxseed; add a little dissolved soap; then when the mixture cools, with a piece of white flannel wipe the gloves, previously fitted to the hand; use only enough of the cleaner to take off the dirt, without wetting through the glove.

To whiten Yellow Flannel. — Dr. Artus tells us that flannel which has become yellow with use may be whitened by putting it for some time in a solution of hard soap, to which strong ammonia has been added. The proportions he gives are $1\frac{1}{2}$ lbs. of hard curd soap, 50 lbs. of soft water, and two-thirds of a pound of strong ammonia. The same object may be attained in a shorter time by placing the garments for a quarter of an hour in a weak solution of bisulphite of soda to which a little hydrochloric acid has been added.

The Arts.

THE "CARBURETTING" OF COAL-GAS.

Every year new patents are taken out for improving the illuminating power of coal-gas by some process of "carburetting," or "carburizing" or "carbonizing" the same. The forms of apparatus are varied, but the *modus operandi* is similar in them all, consisting essentially in mixing with the gas the vapor of a liquid hydrocarbon. Some of the processes are better in their way than others, but the main difficulties still exist — namely, the irregular evaporation of the liquid, and consequently the uncertainty of the light obtained from gas passing through the vapors of the carburizing liquids.

Experiments have been made by an able chemist in order to ascertain the rate of evaporation of liquid hydrocarbon. The material chosen was the spirit of petroleum, as light as it could be procured, being about .700 specific gravity. Three pounds of the liquid were placed in a suitable vessel in such a manner as to expose a large surface for evaporation, and on passing atmospheric air through by means of a motive-power meter, a very large and rich flame, giving off abundance of smoke, was the result. This at first, when adjusted to 5 ft. per hour, gave a light equal to sixteen candles, but speedily the flame became perceptibly less; in a short time it was diminished to a remarkable extent. After twenty-six hours merely a blue light was obtained, and at the end of forty-eight hours no flame whatever existed, as all the constituents volatile at the temperature had evaporated. On re-weighing the residue, barely one half of the total quantity had been available. This clearly demonstrated how easily people may be deceived by a carefully prepared experiment, for at the commencement the air was so highly charged with carbon as to occasion the greatest surprise; but as this was of such short duration on account of the very small quantity of the highly volatile material, the process of carbonizing the air was utterly useless. Many people, however, have been "taken in" by experiments of this very sort. Of course, when coal-gas is used instead of air, the result is essentially the same, so far as any *continued* increase in the amount of light is concerned.

It ought to be understood, moreover, that this process of improving the ordinary gas has been thoroughly tested by the ablest scientific men, and that they have pronounced it a failure. For nearly two years it was tried in the street lamps of London, under the direction and inspection of Dr. Letheby, and yet was abandoned, and has not again been adopted. Great economy, with increase of light, was at that time promised, according to the theory and estimate of the projectors. To ensure economy in the consumption of gas, the ordinary burners, consuming five feet per hour, were changed to those which would consume only three feet per hour. Of course the gas company's bill was materially diminished. But what about the increase of light? Very often the streets of London were in comparative darkness, and so loud became the complaints of the public that the authorities were compelled to order the removal of the carburizing apparatus, and to restore the ordinary five-feet-per-hour burners.

Even where there is a gain by the use o carburetting apparatus, it is rarely, if ever, great as is promised. Twenty per cent. is pr ably about the maximum that can be counted u *as an average* by the very best contrivance of kind. This, considering the uncertainty of light on account of the irregular evaporation which we have referred above, will scarc balance the cost of apparatus and naphtha, extra attention required, and the risk in us so inflammable a liquid.

INDIA INK.

The basis of all the different kinds and quali of India ink is lamp-black, the best of which obtained from pig's-foot and other oils, and so times from resins, while an inferior sort is m from pine wood. The materials are burned i furnace about a hundred feet long, along the si and top of which the smoke condenses. That n remote from the fire and nearest the top is finest, and is carefully kept separate from the r

Glue made from the skin of the buffalo of country is soaked in water for a time until it much swollen, and afterwards completely dissol The lamp-black is then introduced and worked until it forms a soft paste. When the materials thoroughly mixed a quantity of the oil of peas added, and the temperature maintained for a ti at from 110 to 140 degrees, until the paste homogeneous in character. It is then removed separated into little cakes, which are allowed remain for some time drying and becoming mell after which they are strongly compressed in woo moulds, on the interior of which are engraved characters which are seen upon the cakes. surface of the cakes is finally coated with a kin animal wax, which gives a polish, and prevents ink from staining the hands.

The peculiar odor of India ink is produced adding to it, during the process of preparation mixture of Borneo camphor and musk. Only finer qualities, however, receive this addition. Chinese do not use liquid inks, but when they w to write they rub up one of these sticks in wat and use a very fine pointed hair pencil. Those have not tried ink prepared in this way will surprised to find how readily it flows, even fro pen. The durability of such ink is much grea than that of the European, as it does not bec obliterated by moisture or ordinary atmosph agencies.

MEMORANDA IN THE ARTS.

Steam Boilers become Brittle by Use. — Mr. Peter Carmichael recently read a paper u steam boilers before the Scotch Institution of En neers, in the course of which he mentioned tha had been found that "all qualities of iron get h and brittle after the boilers have been at work m than a dozen years, more especially where expo to the action of the fire; and that in the furnac even Lowmoor iron becomes as brittle as comm iron in that time, and great care has to be taken making repairs to prevent the plates from cracki For this reason sixteen to seventeen years is lo enough for a boiler to be in use, at a pressure of pounds to 45 pounds. If used longer, the press ought to be lowered." Two boilers which had be in use nineteen years, and which required repai were found by Mr. C. so brittle that the rivet he on the outside flew off when the inside heads w struck; showing that the rivets had deteriorated much as the plates.

Manufacture of Grape Sugar from Co — Large factories for this purpose have recen been established in New Orleans, Buffalo, a

Brooklyn. The corn is steeped in weak soda lye, or the purpose of softening the husk and gluten, nd is then ground wet, and run through revolving ieves to separate impurities; afterwards it is made o flow through ways or troughs, in which the starch radually settles as a white powder. The wash rater is run into a large cistern, and allowed to erment and produce a weak vinegar. The starch rom the troughs is put wet into the mash tub, and reated with water containing one per cent. of sulphuric acid, for eight hours. The acid is neutralzed with chalk or carbonate of lime, and the liquid vaporated to get rid of the gypsum, and afterwards urther evaporated in vacuum pans, and run into arrels ready for crystallization.

Cement for Leather. — A good water-proof ement or glue, for holding wood or leather, may be nade by dissolving fine shreds of India-rubber in arm copal varnish. The material to be united hould be made clean, and be perfectly dry at the me of applying the cement.

Elastic and Sweet Glue. — Good common lue is dissolved in water, on the water bath, and e water evaporated down to a mass of thick constence, to which a quantity of glycerine, equal in eight to the glue, is added, after which the heatg is continued until all the water has been driven f, when the mass is poured out into moulds, or on marble slab. This mixture answers for stamps, rinters' rolls, galvano-plastic copies, etc. The weet Glue, for ready use by moistening with the ongue, is made in the same way, substituting, howver, the same quantity of powdered sugar for the ycerine.

New Method of purifying Sugar. — M. Iarix has taken, in France, a patent for the appliation of fluosilicic acid for the purifying of beetoot and other saccharine juices. The saccharine uids are first diluted with a sufficient quantity of ater to take away the viscosity of these fluids, sufcient fluosilicic acid is then added to precipitate all e potassium salts present, and next chalk is added saturate any excess of the acid. The fluid is then tered, in order to obtain a clear liquid, and this terwards treated in the usual manner.

The Separation of Animal and Vegetable Fibres. — M. Shervord has invented an ingenus method for the separation of animal fibre from egetable. The process does not alter the structure color of the animal fibre, and permits the use of tton and linen fibre separated from it for numerus purposes. It is sufficient to suspend the goods an atmosphere of nitrogen or carbonic acid, and cause the vapors of perfectly dry sulphuric, osphoric, or hydrochloric acid to enter the room. hese fumes disintegrate the vegetable fibre, and ave intact the animal; the two fibres can thus separated and appropriated to their respective es.

Cold Tinning Process. — M. Daubié, ironaster, Blanc Murger Works, at Bellefontaine, in e Vosges, has obtained a patent for tinning by a ld process, in order to prevent oxidation of iron in eneral, and especially of iron wire, employed in e fabrication of cards and wire cloth, without alring its polish or rigidity. The inventor's chief bject is to prevent the softening of the metal, and e mode adopted is successive immersions in baths ntaining cold solutions of salts of tin, with the ldition of a certain amount of organic matter, ch as fecula or starch, which has always been und valuable both in tinning and galvanization. he solution patented is composed as follows: To ery twenty gallons of water add 6 lbs. of rye flour, nd let it boil for about half an hour; filter it, and terwards add 212 lbs. of pyrophosphate of soda, 34 s. of crystallized salt of tin, 134 lbs. of neutral prochloride of tin, and from 3 oz. to 4 oz. of sulphuric cid. When the salts are dissolved the solution is distributed in eight or ten wooden vats, a little additional water being added to the first two or three of the vats. The wire is passed successively through the whole of the vats, and if great brilliancy of surface is required, also through draw plates at intervals, and the wire, while retaining all its rigidity, becomes covered with a brilliantly polished coat of tin. Beautiful and inoxidizable cards and wire cloth have been produced by this process, which is applicable to wire for a hundred different purposes. M. Daubié has also succeeded in silvering iron wire, by using, in place of the salts of tin in the solution, cyanide of silver and cyanide of potassium.

Agriculture.

SHORE PENCILINGS AT LAKESIDE, No. 2.

SOME THOUGHTS UPON SOILS AND CROPS.

Reclining under the trees on the shore of the Lake in company with a neighbor, the conversation turned upon the different nature of soils and their adaptability to various grains and grasses. Having presented in the conversation some thoughts upon the topics, which resulted from practical experience, we pencilled them down when alone.

It was remarked that long since we had learned in the laboratory that in order to reach certain results, in chemical manipulation, there must be a strict observance of certain laws of combination and association, and also, that no substitutions or omissions could be permitted. To form gunpowder, nitre, sulphur, and charcoal were needed, and one substance was no more important than the other. Sulphur and charcoal had no explosive energy by themselves, nor had nitre and charcoal; but the three combined, when ignited, could overturn forts, or lift mountains. So in agriculture, we have learned that plants can only grow in a normal way, when certain elements are supplied to them. They require carbon, phosphorus, silica, ammonia, potash, lime, magnesia, etc., in order to grow healthfully; and all these must work together in building up the plant fabric. These are all of equal value as sources of nutrition, and it is only by their combined action that a perfect plant is secured. It is absurd to talk about the superlative importance of ammonia, when not a plant exists, or can exist, without phosphorus; it is absurd to talk about potash or lime, as being the one or two things needed to clothe barren fields with verdure, when soluble silica and magnesia are quite as indispensable. The truth is, none of these substances can replace or discharge the functions of another. We may fill our soils with potash, but if the phosphatic salts are absent our crops fail. We may saturate with ammonia, or nitrogenous compounds, and the cereals will not mature without a supply of the other essentials. The results of our experiments have established this point clearly in our mind, that in order to grow crops successfully, *all* the substances needed by plants, must be present in the soil in which they flourish. Some soils furnish all of these in ample abundance, others do not. The former we call rich soils, the latter, barren or impoverished. The soils of cultivatable lands hold in a greater or less proportion all that is essential to the growth of plants. Sometimes one or more of these essentials is largely in excess, or there is more than is needed by any crop for a succession of years; and often one or more is held in small amount, barely sufficient for some crops and wholly insufficient for others. A soil resulting exclusively from the disintegration or crumbling of limestone rocks will be rich in the calcareous element, but deficient in several of the other essentials. Soils resulting largely from feldspathic masses, and granite, will hold quite all that supply the elements of nutrition to plants, and such are therefore good. No two fields or farms are alike as respects the nature of the soil, and therefore when the question occurs, how can this or that farm be restored to fertility, it is necessary to know the general composition of the soil as preliminary to any intelligent attempt to bring it into good tilth. Much of the confusion and doubt which prevail among farmers springs from this difference which exists in soils. Farmers seek for some specific manure which will insure large returns of all kinds of crops, but no such specific exists, nor ever will. There is certainly no specific for our bodily diseases, and therefore doctors, in prescribing, are said to feel their way in the dark. The farmer who is searching for specifics is groping in thick darkness. The intelligent doctor who is acquainted with the constitution and idiosyncrasies of his patient possesses, in the cure of disease, a great advantage over one who knows nothing of such peculiarities. The most proper business of the physician is to study the peculiarities of his patients, and the most proper business of the farmer is to study the physical and chemical peculiarities of his soils. Of course a knowledge of the chemical and geological sciences is of great advantage to a farmer in successfully conducting his labors, but an intelligent observer can secure a good knowledge of the nature of his soils in ten years, and know but little of any of the exact sciences. Without any knowledge of anatomy or physiology, the farmer obtains by observation a knowledge of the peculiarities of his animals. He learns how to feed his pigs so as to fatten them most rapidly and profitably, how to supply nutriment to his cows so as to cause a copious supply of milk, and he learns the temper and habits of his horses and oxen, and accordingly controls them to his advantage. Why should he not learn by observation the nature and capabilities of his fields, and be able to a great extent so to feed them as to obtain the highest and best crop results from year to year? Any farmer, from ten or even five years' observation, can ascertain the extent to which his different fields are retentive of moisture. He must learn how well they withstand the drought or the protracted wet of summer, how different crops behave when the rain fall is small, or copious, in the growing months. Physically considered, some farms are not adapted to the raising of corn, and perhaps some other grains. Corn withstands drought better than almost any other cereal, but that fact affords no reason why it can be raised to advantage on loose, dry soils. Weak, puny corn can be raised in a sand bank, but foolish indeed would a farmer be to plant his corn in such a locality. Corn requires a good retentive soil, a good fair loam, in which to grow in perfection, and if the owner of lands has none such, let him not attempt to grow it. His fields are better adapted to melons, beans, rye, or perhaps wheat. It is useless to attempt to force corn or any of the noble grains

to grow upon naturally wet, or low, clay bottom lands, without thorough drainage and deep tillage. Such are better adapted to grass, and grass farms, if kept in good tilth, are the most profitable of any. Every cultivator of the soil must first become acquainted with the physical character of each parcel he has under his charge, and then he will know what crops are adapted to the several localities.

During the seven years Lakeside farm has been under our care, we have turned over and carefully examined about every rod of those portions suited to tillage. We know its "temper," constitutional and chemical peculiarities, as well as we do the peculiar traits in our horses. We have learned where to plant corn, and where to sow wheat, and not be disappointed in results. We do not fret about wet and dry seasons, as we have proved the important point, that lands can be so selected and cultivated as to place crops beyond their influence in a very great degree. The season last year was particularly unpropitious for corn, and our readers have knowledge of the remarkable yield we secured. The present is fearfully dry and hot, so much so, that farmers in Eastern Massachusetts and New Hampshire, are forced to concede the loss of their late crops. As we look out upon our fields, everything appears green and succulent. Two judiciously selected plats for corn are covered with luxuriant foliage, and from the promise afforded, we predict a yield nearly or quite equal to that of last year. Fifty tons of hay have been mowed from fields which, seven years ago, gave but about a dozen. It is certain that farmers must study the nature of their soils, and their adaptability to the different crops which it is thought desirable to raise. By drainage and deep tillage the physical condition of most lands can be completely changed, and with the supplying of such chemical agents as are needed, crops of every description can be raised, satisfactory and remunerative to the husbandman.

FODDER CORN.

THE *Rural New Yorker*, in a recent issue, presents some analyses of fodder corn, which are designed to show that Dr. Loring's views regarding its value as feed for milch cows are erroneous. What Dr. Loring's exact notions are, we do not know, and we do not care to inquire. Facts and principles in agriculture do not rest upon the mere opinions of any man. Opinions should only receive consideration when they are supported or based upon accurate observation and careful experiment. We have in the JOURNAL and elsewhere given the results of experiments, which lead us to place a low estimate upon the value of fodder corn as grown under the usual or ordinary conditions among farmers. Upon this subject, which is regarded as of importance by many, we do not wish to be misunderstood. We have distinctly stated, that it is the corn fodder produced from broadcast sowing, or in drills when in close contact, which is comparatively worthless; not that grown in hills, or drills wide apart, properly cultivated, and cut just before the ears commence forming, or when they are in the milk. No one can place a higher estimate upon the maize plant as fodder for milch cows, than we do, if it is *properly cultivated with full access of light and air.* Can farmers afford to cultivate a *hoed crop*, to feed to cows in a green state? We think not, as a general thing. There are crops which we have pointed out, which serve a good purpose as green feed, which can be raised from broadcast sowing and left to grow under the conditions of ordinary grasses. The matter of cost and convenience in raising crops of any kind must be left to farmers themselves; they ought to be the best judges. It is, however, important that they should clearly understand the modifying influences of culture, air, and sunlight upon different kinds of vegetable productions.

KANSAS AS A FIELD FOR EMIGRATION.

THE *Kansas Farmer*, in an article of considerable length and apparently written with impartial accuracy, answers a series of questions put by an Eastern inquirer respecting the advantages of that region for agricultural emigrants. We give a brief summary of the main points in the article, thinking that they may be of interest to some of our readers.

Kansas is as healthy a State as any in the whole Western country. Notwithstanding the immense return of unharvested vegetable matter to the earth by decomposition, the turning up of hitherto undisturbed earth by the multitude of new comers, and the privations and hardships of pioneer life, the region is still free from serious epidemics and malarial diseases. Residents upon the bottom lands, who live in temporary houses, set upon the ground and in the timber, and who use surface water, suffer more or less from chills and fever. The climate is no more to blame for this, however, than is the fire for burning a finger thrust into it, in defiance of well understood natural laws.

The average temperature is mild, and the atmosphere dry. Snow is unusual, except for a few days at a time. The unpleasant feature of the winters is sudden and severe changes, the mercury sometimes going below zero in many localities. At these times a change of thirty to fifty degrees in twenty-four hours is not surprising. These "cold snaps," however, are of short duration, ordinarily culminating inside of three days, followed by a resumption of mild, agreeable weather.

Water is good in Kansas, as a rule. Enduring water is reached at a depth of twenty to seventy feet, the average being but little above the first named depth. Springs are abundant and pure as those gushing from the sides of the Green Mountains. Prof. G. C. Swallow, who made a geological survey of Kansas, says in his official report: —

> "Kansas is well supplied with streams of living water. . . . Almost every farm has a good supply of never-failing springs. . . . But few countries are better supplied with running streams and perennial springs; and few have such easy methods of obtaining artificial supplies of pure water."

There are good farming lands, that can be taken by homestead and preëmption, and some timbered land so open; but timbered claims are not so easily obtained. They lie in the northwest and south portions of the State. For specific information touching the west and north, address George W. Martin, U. S. Register, Land Office, Junction City. For south and west, address Watson Stewart, U. S. Register, Land Office, Humboldt.

These lands are adapted to the most diversified, and therefore most desirable and safe, sy tem of culture. Cereals, fruits, and grasses ar produced, in quantity and quality equal to thos of any part of the country. Stock-raising an after question, a simple question of econom depending upon location with reference to ma kets. As a rule, the products of the soil shoul be converted into meat, to attain the highe profit, unless grown in close proximity to a gre market of consumption.

Stock farming is *sure* in Kansas, if it is cor ducted with ordinary intelligence; but no or should go there with the expectation of keepin stock, particularly sheep, without protection winter feeding. As mild as are the winter stock should be protected by good and sufficie cover, and should have *plenty* of hay, with *son* grain.

In closing, the *Farmer* says that "the imm grant will find a hearty welcome by a peop second to none in intelligence and energy, i this or any country. He will find a people p lite and generous, yet self-reliant, and bitter hostile to *drones*. The man of indolence an indecision has no place in Kansas. Such ma *stay* here, and think they live; but to the bus bustling, whirling masses they are dead an buried, out of thought and memory."

PRUNING DWARF PEARS.

AN experienced pear culturist says that he h examined thousands of dwarf pear-trees in th grounds of others; and has never seen goo healthy, vigorous trees where annual pruning h been omitted. Near his orchard, which contai two thousand healthy, thrifty dwarf pear-trees, neighbor planted trees at the same time, obtain from the same source, and of the same age as hi This neighbor pruned a little the first and seco years; but last year, his trees being full of blosson buds, he allowed them to bear and left them u pruned. The season was a dry one, the fruit di not fully mature, and now from one half to tw thirds of the trees are dead; while trees on whic the previous year's growth of wood was cut bac from one half to two thirds are healthy and vigo ous, and had an abundance of fruit-spurs and bud

FOWLS VERSUS WORMS. — M. Giot, a Frenc entomologist, has lately found new employment f fowls. He says that French farmers have, durir the past year, complained bitterly of the prevalen of worms, which infest corn and other crops, th highest cultivated fields being the most infeste Fowls are known to be the most indefatigable wor destroyers, pursuing their prey with extraordina instinct and tenacity. But fowls cannot conven iently be kept upon every field, nor are they want there at all seasons. Therefore M. Giot has invent a perambulating fowl-house, which is described follows: "He has large omnibuses, fitted up wi perches above, the nest beneath. The fowls a shut in at night, and the vehicle is drawn to the r quired spot, and, the doors being opened eve morning, the fowls are let out to feed during th day in the fields. Knowing their habitation, the enter it at nightfall without hesitation, roost, and la their eggs there."

SEWAGE MANURING. — Experiments with sev age as manure have thus far proved entirely succes ful in England. At Barking, the fourth consecuti crop of wheat is now growing upon land treated i this way. The stalks are about five feet high, wi ears of great length.

SOME OLD INVENTIONS.

There are several inventions and art processes egarded as very new and wonderful by the nultitude, which seem quite old to us. We ave watched the progress and adventures of hese art processes and devices for many years vith the same interest that parents watch the areer of their children, for the reason that they re indeed the children of our brain. Many of ur readers have doubtless noticed the huge piles of vhat is called "leather board," heaped upon the idewalks and in the leather stores of our cities. Sixteen years ago we made the first sheet of the rticle ever produced in the United States, or n the world. Noticing the immense heaps of "leather scraps" (the worthless refuse of shoe actories), which are seen in New England owns, we conceived the idea, in 1854, of attempting to utilize them by disintegrating, or earing them into fine shreds, and forming from he particles a cheap leather board which might erve many useful purposes in the mechanic arts. An old paper mill, belonging to the late Mr. Flagg of Exeter, New Hampshire, was hired for the purpose of experiment, and after surmounting many difficulties, we succeeded, during the year, in manufacturing several tons of the new article. As soon as the problem was fairly worked out, it was allowed to pass into the hands of other parties who have since carried on the manufacture upon an immense scale. No patent protection was sought, and no remuneration for our labors has ever been received. An exclusive right to make this article, on a patent protection, would have been worth a great many thousand dollars. Although the production of the "patent leather," as it is often called, has been of advantage to producers, its invention has not been particularly advantageous to the consumers of shoes. The interior "soles" of most cheap shoes are now constructed of this material, and when water penetrates into them, the result shows that it is a poor substitute for good leather. We fear that "*pater familias*" will never thank us for devising "leather board."

Twenty-three years ago, we engaged in a series of extended experimental investigations upon the hydrocarbon liquids, and one of the results of these labors was the production of an apparatus for lighting buildings by employing air for the conveyance of the light vapors to gas burners. From this invention have come all the "portable gas machines," "gasoline apparatuses," "air lights," "automatic gas" devices, which are so numerous in our cities. Every one of these is claimed as "very *new*," and all are covered by "patents." The perusal of an article published in the *Traveller* newspaper of this city in 1849, describing the results of our labors, will show that but few important improvements have been made in our original devices, during more than twenty years. Sixteen years ago we constructed an apparatus for extinguishing fires by the employment of carbonic acid, or aerated water under pressure. The instrument was almost precisely similar to the one now claimed as *new* and owned by a company who control the *right* to make "Fire Annihilators." We did not at the time we invented the apparatus, nor do we now, regard it as of much practical importance. Nearly seventeen years ago we put in position the first apparatus for cooling mineral waters and syrups at the place of outlet, or upon the counter of the dealer. All the new "soda water" devices seen in the shops are based on our original device, and are but modifications of our invention. Upon this no patent protection was secured, but we have been informed by an extensive manufacturer that its value at present would be not less than *fifty thousand dollars.* The numerous devices which have been lately introduced for protecting lamps and fluid cans from explosions are simply the reappearance of contrivances which we made public twenty or more years ago. At that time we covered metallic lamps with glass, and prevented flame from entering the reservoir by a chamber of wire gauze; and also some wick arrangements, now claimed as new, are found in our old lamps. Time is worse than wasted in endeavors to make lamps *safe* which are designed to hold and burn dangerous, inflammable liquids. More severe accidents are caused by spilling and igniting the liquids than by explosions. The inflammable light napthas sold so often as kerosene, cannot be harbored in any dwelling with safety. No matter what lamps or cans are used, the danger is not in any important degree removed by their agency. There is safety only in expelling everything of the kind from household use.

We might increase the list of so called "new inventions," which originated with us many years since, but our object is not to "tell what we have done," but to present some reliable examples, illustrating the nature of many of the "new patents" which are constantly thrust upon public attention. Our readers may have reason to thank us for affording them some insight into the merits of the claims of those who seek from them pecuniary assistance.

A NEW ARTIFICIAL LIGHT.

The *Berggeist* describes a new artificial light which has recently been successfully experimented with. It is the Philipp carbo-oxygen lamp, and its trial during the month of March, at Cologne, was such as to win approval on every hand. The system of lighting is distinguished from those already in existence by its simplicity, its brilliancy, and, moreover, by its less noxious character. The light is generated by the simultaneous combustion of a liquid chemical compound and a current of oxygen, in a suitable lamp. The gas is derived from the atmosphere either by chemical or mechanical means; the chemical methods being to act upon the oxygen of the air with chloride of copper (Mallett's method), or with manganate of potash (Tessié du Motay's method), while the mechanical mode is that of utilizing the different degrees of solubility of nitrogen and oxygen in water or other liquids. By compressing atmospheric air into receivers filled with water, a portion of the nitrogen is taken up by the water, while the oxygen remains insoluble in the water; the air, thus containing a goodly proportion of oxygen, is forced into a second reservoir of water, where a further amount of nitrogen is absorbed, and after the operation has been repeated seven or eight times, an atmosphere is obtained containing 97 per cent. of oxygen. The nitrogen which has been separated is made use of in a well-constructed apparatus, as an auxiliary to the motive force. Experiments have established the fact that a flame fed with air containing 53 per cent. of oxygen yields a light equal in brilliancy to that obtained with pure oxygen, and with diluted oxygen of this kind the Philipp flame has a brilliancy of 90 to 100 candles, or ten times that of an ordinary gas jet. The light is of a bluish white, resembling very much that of electricity and magnesium. The liquid employed consists of liquid hydrocarbon, very rich in carbon; it costs but little, burns economically, and can be employed only in this particular direction. The combustion is maintained in a lamp — Philipp's carbo-oxygen lamp — fitted with a wick, into the flame of which the oxygen penetrates in a horizontal direction. The flame is thus made to assume the form of a star, and any heating of the wick-holder thereby prevented; if of the size and power above mentioned, the quantity of gas consumed is $5\frac{1}{2}$ cubic feet per hour. As to the lamp, no special attention is necessary beyond that of filling it with liquid, as the wick is of a very durable nature, and needs no trimming. The hydrocarbon employed is patented both in Europe and in America. This method of lighting is, we believe, likely to be adopted very widely. Independently of its simplicity and reasonable cost, which are, indeed, extreme, it possesses the very eminent and valuable qualifications of perfect security; no explosion is in any way possible.

Chemistry of the Farm and the Sea. — This little book, which we permitted Messrs. A. Williams & Co. to publish two years since, has passed through several editions, and meets with a ready sale. We are constantly receiving letters from near and distant parties, thanking us for the book, and assuring us that great pleasure and much information has been derived

from its perusal. Mr. Wm. F. Cox of St. Genevieve, Missouri, writes under date of July 17th, that he is so well pleased with it that he has ordered four more copies to present to his friends. It is certainly gratifying to be able to contribute to the happiness and stock of knowledge of others through the medium of books, or in any other way.

EDITORIAL NOTES.

New Developments in Adulteration. — In our last we referred to cream of tartar, without any cream of tartar in it, as one of the latest "dodges" of adulteration — if adulteration it could be called. We have since read of another sample of the same article which contained more than 90 per cent. of sulphate of lime, and not one particle of bitartrate of potash. It would have been dear at five cents a pound, and was sold as "extra fine" at fifty-five cents.

There has also been a new development in the adulteration of coffee. People have flattered themselves that if they bought the coffee beans raw, and roasted and ground them at home, they were sure of having the genuine Mocha or Java; but artificial coffee-beans are now made, like bricks, from a greenish clay, and the eye cannot distinguish them from the natural article. They are made in moulds, a hundred at a time, and cost about a cent a pound. When roasted they absorb the brown color from the genuine berries with which they are mixed, and the true and the false are still undistinguishable. This admixture of clay is not injurious, as it settles to the bottom of the coffee-pot, giving a literal significance to the term *grounds* as applied to that familiar sediment. The beverage is weaker, of course, but otherwise no worse; indeed, we suppose that some dietetists would say that it is all the better for the inert addition to what they consider an unwholesome decoction. The fraud may be detected by breaking open some of the raw berries and examining them closely, or by chewing them; or, as some one has suggested, you can make a microscopic examination of the interior of each berry!

Potato "Reconstruction" in Paris. — These Yankee achievements in the fine art of cheating are not to be easily surpassed, but we are not sure that our Gallic friends may not cheat us of our laurels. In Paris they manufacture "new potatoes" out of old ones by the following process: the potatoes are put into tubs half-filled with water, and are vigorously stirred about by the feet of workmen until the dark skin has been rubbed off, and they acquire a smooth and satin-like appearance; they are then dried, neatly wrapped in paper, and arranged in small baskets, which are sold in the markets for five francs each. The *rafistoleurs* make no secret of their trade, and may daily be seen at work on the banks of the Seine, within sight of the Hôtel de Ville.

Not afraid to say he didn't know. — Dr. Allnatt, the other day, sent the following inquiry to Prof. Tyndall: "Schönbein believed that ozone could not exist without the production of its antagonistic congener, antozone. When ozone-tests, fully colored to their maximum hue, become blanched by exposure to the air, is the bleaching to be ascribed to the action of elemental antozone?"

Professor Tyndall replied as follows: —

"Dear Sir, — The answer to your question regarding the action of ozone and antozone is brief, but full. It is thus: I do not know; nor do I believe that anybody knows.

"Yours very faithfully, John Tyndall."

The Purifying of Rivers. — The general result of the investigations of Dr. Frankland and the Government Water Commission, amounts to a denial of the current notion that sewer-water, mixed with the stream of a river, is purified by the combustive action of the oxygen dissolved in the water. He maintains, on the contrary, that there is no river in England long enough to effect this combustion completely and satisfactorily. It is true that, after a short distance, the river-water becomes limpid, and less loaded with organic matter; but that is because the greater part of the organic matter in suspension has fallen to the bottom, and is deposited with the mud. The source of infection has merely changed its time and place. The spores which are capable of transmitting disease resist both modes of separation. To purify sewer-water, the Commission sees no other practicable means than filtration through the earth, which it serves to manure and enrich.

The Nature of Yeast. — At a late meeting of the London Chemical Society, the President, Dr. Williamson, gave a brief review of the present state of knowledge of the yeast plant. Though called a "plant," the yeast organism appears in all its functions rather animal than vegetable; the products of its secretion are less complicated than those it takes in; it does not, like plants, require light for its vital process; neither does it absorb heat, but on the contrary gives it off.

Physical Science at Oxford. — Some mischievous Oxford students, not long ago, destroyed several valuable pieces of statuary by building a fire under them. They afterwards gave themselves up to the college authorities, and pleaded, in extenuation of their offense, that they only meant to blacken the sculptures with smoke, and didn't know that fire would convert marble into lime. Very likely they didn't, and the fact is a suggestive commentary upon the neglect of science teaching in the great English University. There begins, however, to be a reform in that respect, both at Oxford and at Cambridge.

Commendable Caution. — One of the best of our city exchanges was lately the victim of a "sell" in regard to a pneumatic tube 400 miles long, and now naturally looks with a suspicious eye upon the account of the device for supplying locomotives with water while they are in motion, which has been in use for some time in England (we saw it there two years ago), but has only recently been tried in this country. This is what it says about it: —

"An improvement, or possibly a hoax upon the credulous, is described in the *Poughkeepsie Eagle*. The invention is said to be a trough in the centre of the track, kept full of water, from which a locomotive can, by an ingenious apparatus, take up a supply for the tender, when running at the rate of thirty miles an hour! The account does not state how the novelty is to work in zero weather. If the story is a true one, and the experiment as successful as reported, there can be through trains without any stoppages."

Of course, the thing is *not* feasible in freezing weather, but it works well at other times, and we do not see why it should not be generally adopted for express trains on our railways.

Boston Milk. — We have received the "Eleventh Annual Report of the Inspector of Milk" for this city. Of 1,680 samples of milk inspected, 520 were more or less "extended." The average watering of the stock was 28 83 per cent., the minimum being 19.25 and the maximum 41.87, or *nearly one half*. The daily supply of milk for the city is put at 20,948 gallons, for which the consumers pay $7,122.32. The milk-bill for the year figures up to something more than *two and a half millions* of dollars.

The adulterating material used is almost invariably water. Mr. J. F. Babcock, the Analyst, says that he has never detected the chalk, sheep's brains, starch, flour, etc., which books on this subject mention as sometimes added to milk. Salt is occasionally added to bring up the specific gravity reduced by the addition of water, and burnt sugar is used to neutralize the blue tint of the diluted liquid. To prevent souring carbonate of soda is sometimes put in. With these exceptions, water is the sole adulterant employed in the manufacture of "milkman's milk" from the genuine article.

Hydrogen Manufacture. — Du Motay and Maréchal have suggested a new process for the preparation of hydrogen on a large scale. It consists in heating to redness a mixture of damp coals and alkaline hydrates. The mixture of hydrogen and carbonic acid thus disengaged is conducted over certain carbonates, which retain the carbonic acid and become bicarbonates. The pure hydrogen is collected in a gasometer for use. The bicarbonates are employed as such, or as sources of carbonic acid. The oxides produced by the carbonization of the alkaline coals may be utilized for the purposes of agriculture or other industries, or, better, to form the hydrates for subsequent operations. The same chemists also propose to obtain pure hydrogen by passing ordinary illuminating gas over lime heated to cherry redness; the dry residue will be carbonate of lime.

Milk as a Preventive of Lead Poisoning. — M. Didierjean, a red lead manufacturer in France, states that he tried every possible way to keep his workmen in good health, but did not wholly succeed in preventing lead colics until by mere accident he found out that two of his men were never affected in that way. Inquiry brought out the fact that these men regularly took milk as a drink with their meals. He was thus led to try the experiment of making the use of milk (a litre a day) compulsory with the workmen, and he has succeeded by this means in keeping all of them free from any symptom of lead disease for the past eighteen months. The absolute correctness of this statement is confirmed by good authority. The remedy is a simple one, surely, and it ought to be thoroughly tested by every person exposed to the danger of lead poisoning.

ATOMS.

The steam power employed in this country is equal to 130 millions of men, but that of Great Britain is vastly greater, being equal to 400 millions of men. — A "soap mine" has been discovered in Pennsylvania — in other words, a great deposit of a peculiar kind of clay, which resembles soap, and can be used for washing purposes like that substance. — A nugget of pure copper, weighing 117 pounds, was discovered the other day in an Iowa field, where it had been kicked about for years, being taken for a common stone. — A diamond from the Cape of Good Hope, lately brought to England, weighed 186 grains after cutting. — A Vermont marble company has sent a block of statuary marble to Italy. — Arrangements have been made to run trains from New York to Chicago in twenty-four hours. — Fifteen thousand miles of railroad are now under contract in the United States, which, finished and furnished, will cost about 750 millions of dollars. — A steam omnibus is now running regularly between Edinburgh and Portobello, a distance of three miles. — Experiments have been made in Cornwall in lighting mines with gas, and the report is that the new method is one third cheaper than lamps or candles, to say nothing of its greater safety. — A single manufactory in Edinburgh makes an amount of chloroform which would furnish eight thousand doses a day. — Sour milk is recommended for keeping the leather of kid boots soft. — Charcoal biscuits, which are largely used in England, can be made by subjecting ordinary biscuits

to a current of superheated steam between 500° and 600° F. — The velocity of nerve force in the motor nerves of a frog is estimated by M. Helmholtz at one hundred and ninety feet per second, — which is at the rate of 11,400 feet, or a trifle over two miles a minute. — Artificial india-rubber is made in Paris by a mixture of gelatine, glycerine, etc. It has all the properties of the genuine gum, and costs only 25 cents a pound. — Filters filled with black oxide of iron are very effectual in removing organic matter from impure water. — The heaviest liquid known, except mercury, is a compound of thallium and alcohol, which is about three and a half times as heavy as water. — Carbonic acid has been converted into oxalic acid by passing the dry gas over sodium at a high temperature. — Dry litharge and glycerine, made into a stiff paste by stirring, and used immediately, form an excellent lute or cement for chemical apparatus. — There are in America and Europe more than 250 manufactories of india-rubber articles, employing some 500 operatives each, and consuming more than 20,000,000 lbs. of gum per year. — Out of the total area of Great Britain 30,339,000 acres, or 53 per cent., are under cultivation. — The raising of the tea plant promises to succeed in California. 300,000 plants are now growing there, and doing well. They are mostly under the care of Chinese and Japanese laborers. — Small quantities of glycerine are added to paper stock to give the paper greater flexibility, and especially to give copying paper the quality of taking up color readily. — Valuable gold mines and vast salt fields have been discovered on the table lands of Thibet. — Vienna is to be supplied with water by an aqueduct from the Styrian Alps. — Chromate of lead, a dangerous poison, is extensively used in the adulteration of sugar. — Dr. Poselger has proved by experiments that trees are not injured, as has been supposed, by the leakage of street gas pipes. — The farm products of the United States for 1869, are estimated by Secretary Wells, at $3,282,950,000, which is nearly half the grand total of all the productions of the country or $6,825,000,000. The three heaviest items are corn, 450 millions; wheat, 375 millions; and cotton, about 300 millions. — California has 800,000 peach trees, or about five to each voter. — The average price of meat in Russia is about five cents a pound. 200,000 tons of tallow are yearly made there. — A few leaves of green wormwood scattered in places infested with black ants, will dislodge those insects. — Chloral is still the predominant topic in the medical periodicals. — It is asserted that the bite of the cobra, or any other poisonous snake or reptile, can be cured by administering a preparation of the gall of the venomous creature.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home, science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

E. J. S., Hyde Park, Mass. The substance known as *bird lime* is a green, viscid, and tenacious mass, and is made from the bark of various shrubs, but principally from the common holly. The middle bark of the holly contains a large amount of viscid matter which is extracted by boiling; this is allowed to ferment, evaporated to a paste, beaten in a mortar, and afterwards packed in jars for use.

H. W. J., Cleremont, N. Y. Permanganate of potassa cannot well be prepared and retained in pill form. It should be used in its dry crystalline condition, or in solution.

A. M., Waterloo, N. Y. To answer properly the questions you propound, would require the space of at least one entire page of the Journal. A good pipe for sewage purposes, is the common glazed clay pipe. This you can obtain of the dealers, of any size required.

T. H. W., Thompsonville, Ct. Thank you for pointing out the error. The subject matter of physicians' prescriptions, as you suggest, should be discussed, and a reform brought about in the method of writing them.

S. B., Barnardstown, Mass. Your experience with steel pens does not afford satisfactory evidence that palsy is produced by their use. The difficulty you describe arose probably from nervous weakness, and want of air and exercise. We do not think that what are called "steel" pens ever produced a case of palsy by any direct or indirect agency.

J. F. J., Northborough, Mass. The horn shavings and saw dust, the products of comb factories, are very valuable fertilizing substances when properly prepared and applied. The shavings may be "rotted" or made to undergo putrefactive change, by layering them with moist soil or peat. Make a heap: first a layer of soil three inches deep, then a layer of thin shavings or dust, then another layer of soil, and in this way make the heap four or six feet high. Keep it moist, and in a month or two it will ferment, and the horny structure of the shavings will be destroyed. They may also be fitted for soil use by dissolving them in a bed of fresh ashes, or in potash water. The manure formed from them is highly nitrogenous, and must be used sparingly. A handful put in a hill on moist ground, and a cabbage plant set in the hill, will give extraordinary results.

J. O. T., Kittery, Me. Use an iron pipe in your artesian well. It is the only pipe you can use under the circumstances.

M. S., Groton, Mass. A strong solution of cyanide of potassium will remove silver indelible ink from linen. It is, however, poisonous, and must be used with care. Dilute hydrochloric acid, made by adding five parts of water to one of acid, will remove the stains. It should be washed out with pure water soon after using it.

M. V. S., Ogdensburg, N. Y. Our correspondent informs us that she is a "victim to dyspepsia," and wishes to know how much food she can take at meals without doing harm. If she is troubled with indigestion, we think this important question ought to have been settled to her satisfaction long ago. A dyspeptic generally knows when he or she has eaten too much, as the pangs of an overloaded stomach are of such a nature as not to be easily misunderstood. The question is too difficult for us to answer.

R. S., Montpelier, Vt. Horse-hairs never turn into small snakes. This is one of the vulgar notions that has obtained wide credence, and although contradicted a thousand times is still believed in by multitudes. The long, tiny worm which resembles a horse-hair, and which is found in ditches and puddles of water, is of a regular order and family, and well understood by naturalists.

T. O. N., Providence, R. I. Both the Urbaniste and Glout Morceau varieties of pear-trees are very slow in coming into bearing, and you must patiently wait for the fruit to appear. We have vigorous trees, eight years old, which have never produced a single specimen. It is provoking, but it is the nature of the tree.

M. N. O., Washington, D. C. Mildew is a fungoid plant which has life or vitality like other parasitic growths. Examine it under a microscope of 300 diameters, and its wonderful and beautiful structure will become apparent.

E. M. P., Granby, Mass. You are quite right in your suspicions. The parties are wretched quacks, and will be fully exposed in due time. The matter is explained elsewhere.

A. H. H., West Sand Lake, N. Y. — The following is a recipe recently sent us for an ink which is very black and which keeps well: —

Ext. logwood	4 oz.
Sulphate of copper	1 "
Nutgalls	15 "
Sulphate of iron	6 "
Gum Arabic	6 "
Cloves	2 "
Rain water	3½ qts.
Vinegar	4 oz.
Pyroligneous acid	8 "

A little carbolic acid may be added. This, with the pyroligneous acid, will prevent the ink from mildewing. The cloves alone do not answer this purpose, but they give the liquid an agreeable odor.

J. B., San Jacinto, Texas. Ivory may be bleached by keeping it in a thin milk of lime (made from freshly slaked lime, and heated) until it is white. It should then be dried and polished.

John H. Williams, M. D., who sent us $1.00 some time ago, forgot to name his P. O. address.

Wm. A. Fry, of Worcester, sends us $1.00, but neglects to mention his *State*. There are *four* post-offices of that name.

Water Supply Pipes. — The remarks presented in our last number respecting the dangerous nature of galvanized iron water pipes, have created a wide-spread interest, and considerable anxious inquiry has arisen regarding the best and safest pipe to use for water conduit. The whole subject of water supply pipes will be discussed in the October number of the Journal, and we trust the paper will not only be interesting but useful.

Medicine.

THE VALUE OF VACCINATION.

The prevalence of small-pox in Paris has led to a thorough re-discussion of the value of vaccination, the various methods of performing it, and all the related questions; and renewed attention has thus been called to the subject among medical men in this country also. The almost unanimous verdict, both here and in Europe, is in favor of vaccination. A Medical Commission appointed by the hospitals of Paris, speak as follows in their report: "We all know that in some cases the benefit of vaccination disappears to such a degree, that certain persons having beautiful vaccinal cicatrices succumb from confluent variola, or, more often, from the malignant, and especially the hemorrhagic forms; we know that a larger number of vaccinated persons are attacked with variola discreta, which sometimes present great gravity, and may terminate by death; but we also know that these facts are only the exception, and that the majority of vaccinated persons are only lightly attacked; and on the contrary, we are not ignorant that, if it happens that persons not vaccinated are slightly attacked, this is by far the greater exception; and that, for persons not vaccinated, when attacked with small-pox, the danger, the confluence, and the malignity constitute the rule and not the exception." The Commissioners give statistics taken not only from the present epidemic, but from former ones, in proof of these assertions.

Dr. Baroffio, in his report on vaccination in the Italian army, states that the number vaccinated in 1868 was above 57,000. The good effects of vaccination and revaccination are constantly becoming more apparent. The mortality from small-pox, which formerly was nearly 7 per cent., had fallen in 1863 to 4 per cent., and in 1868, was little more than 3½. Dr. Baroffio expresses a favorable opinion of the plan of taking the lymph from healthy and strong infants, and then transmitting it from arm to arm among the soldiers.

In Russia, vaccination is not compulsory, and, according to official returns, no less than 10,350,000 persons have died of small-pox in that country during the last seventy years.

In England, of every 1,000 deaths from 1750 to 1800 there were 96 deaths from small-pox; but since the introduction of vaccination the number has averaged only 35 out of every thousand, or a diminution of nearly two thirds. The regular decrease for the first sixty years of the present century is well shown by a table prepared by Dr. E. C. Seaton, Medical Inspector to the Privy Council. He gives the number of deaths from small-pox out of each 1,000, in London, for the successive decades from 1800 to 1860 as 64, 42, 32, 23, 16, 11. From this it appears that the mortality from this disease for the years 1851–1860 was only about *one sixth* of that for the years 1801–1810.

In Germany, before vaccination was known, the deaths from small-pox were 6.65 to the 1,000, but since its introduction they have averaged only 7.26 to the 1,000, — a reduction of *nearly 90 per cent.*

Dr. William Pepper, one of the physicians to the Philadelphia hospitals, in a valuable article on vaccination in the *American Journal of the*

Medical Sciences, arrives at several distinct and decided conclusions, which are in substance as follows: —

1. Vaccination appears to furnish almost complete protection against either varioloid or variola, during the first six years of life.

2. In subjects not vaccinated, the greatest susceptibility to the variolous poison seems to be during the first two years of life, at which time the form of the disease is very apt to be confluent, and in a large proportion of cases fatal.* The same tendency to assume the grave form of true confluent variola in unprotected subjects may be seen, though to a less degree, at all ages.

3. When, owing to any cause, whether from possible inertness of virus, imperfect insertion, or idiosyncrasy on the part of the subject, the vaccination fails, the operation should be repeated at short intervals, varying the virus and perhaps the mode of insertion until success is obtained or all danger of exposure to contagion ceases.

4. In very many cases, however successfully vaccination may have been performed, its protective power becomes exhausted after a number of years, although there is very little risk when vaccination has preceded the exposure by so short a period as two years.

5. When the protective power of vaccination has been exhausted, the subject may contract any form of variolous disease.

6. Notwithstanding this possibility, the chances are very much more in favor of an attack of varioloid or a mild form of variola, when the subject has been vaccinated successfully, no matter how long before, than if this operation had not been performed.

7. Although the tables furnish meagre evidence of a positive kind as to the absolute power of vaccination to protect against death from variola, they furnish strong negative evidence in its favor.

8. If vaccination is performed during the incubation of variola, at such a time that the vaccine eruption appears before the variolous eruption, the latter will be modified, and, in the vast majority of cases, favorably.

* We may remark that this view is confirmed by the French report from which we have quoted above. The mortality in Paris was very great among children less than one year old — ten times greater than between the ages of 20 and 30. To children under three months of age it was especially fatal.

THE HEALTH AND LONGEVITY OF BRAIN-WORKERS.

Dr. G. M. Beard, in an article in the *College Courant*, gives many facts and statistics to show that brain-work is *per se* favorable to health and longevity.

The earliest records of average longevity are those of Upianus, 225 years B. C., and relate chiefly to the *intelligent and wealthy* classes. His table makes the average length of life for persons under 20 to be 30 years; for those between 20 and 25, 28 years. In England, at the present day, the average length of life for *all classes* is 46 years for those under 20, and 38 years for those between 20 and 25. In the United States the average expectation of life for all persons under 20 is 47 years; for those between 20 and 25, 39 years. In other words, all classes live 50 per cent. longer under the modern civilization of England and the United States than the most favored brain-working classes lived under the Roman civilization.

In all nations the higher classes live longer than the humble.

Increase of longevity is shown by comparison, not only of ancient and modern times, but also of the earlier with the later stages of our modern civilization.

Thus in Geneva, where vital statistics have been carefully kept for nearly four centuries, the expectation of life —

In the 16th century was 21.21 years.
" 17th " " 26.67 "
" 18th " " 33.62 "
From 1814 to 1833 " 40.68 "

This comparison shows an increase of almost one hundred *per cent.* in three centuries. As the civilization of Europe and America has been mainly developed during the past three centuries, the comparison is a fair one.

In Sweden the expectation of life at birth —

From 1755 to 1775 was $35\frac{1}{4}$ years
" 1841 " 1855 " $43\frac{3}{4}$ 5-12 "

In England and Wales mortality has diminished *two fifths* in a single century — from 1720 to 1820.

The rate of mortality in Dublin at the beginning of the eighteenth century was 1 in 22 of the population; in the middle of the nineteenth century 1 in 38 of the population.

The rate of mortality in Boston —

From 1728 to 1752 was 1 in 21.65 of the population.
" 1846 " 1865 " 1 " 42.08 " "

Here we have a decrease of about fifty per cent. in one century; and similar decrease has been observed in Paris and London.

It is just to conclude that this very remarkable increase in the average duration of human life under civilization is materially due to the influence of labor of the brain. This is, however, by no means the only cause of this increase of longevity. There are various other causes that are associated with and flow from increased mental activity of nations. Among these may be mentioned —

1. Increased comforts. Civilization gives us better food and drink, better homes and clothing, better surroundings every way, than barbarism.

2. Diminished hours of labor, with better reward. Excessive muscular labor is more injurious than excessive mental labor, especially when it is ill-paid, and pursued under depressing circumstances.

3. Improved morals. Intemperance and licentiousness, the two great foes of the human race, have both diminished with the advance of civilization.

4. Advance in sanitary and medical science. The types of disease have changed, and some forms have passed away. The plague, which in the seventeenth century destroyed thousands every year, and the "black death," which destroyed 25,000 in 1348 and 1349, are now unknown. Small-pox is but 1-10, measles 1-5, fevers 1-4, and consumption a little more than 1-2 as fatal now as in the seventeenth century. Nervous diseases have lately increased in severity and variety, but they are much less fatal than fevers and epidemics. Meanwhile hygiene and medical science in all its branches have rapidly advanced.

PROFESSOR HUXLEY ON MEDICAL EDUCATION.

Professor Huxley distributed the prizes the other day, at the University College, to the medical students, and made an address to the audience. Speaking of medical education, he said he had, for twelve or thirteen years, been an examiner in the University of London. Although the men who came up there were the pick of the London schools, he had found them all laboring under certain disadvantages, owing to the defective system of education now pursued. What struck him, during his long experience of the best instructed of the medical schools, was the singular unreality of their knowledge of physiology. He did not complain of the quantity, for there was, if anything, too much of it; but he did quarrel with the quality. He had invariably found that the men who came up for examination did not know their physiology as they did their anatomy. The number of schools in London rendered it almost impossible that competent men could confine themselves to the teaching of the theoretical branches of the profession. Anatomy, which lay in the direction of practice, might be thoroughly taught, but this was not so with physiology. From the very nature of the case, the occupant of the physiological chair remained there until he had achieved professional success, and then he left it; he was clothed, but physiology was bare. The remedy he suggested was the centralization of the teaching of the theoretical branches of the profession in not more than three central institutions, where able professors could be maintained. He would cut down these theoretical branches to a considerable extent, and would have the elements of physical science taught in the primary schools — physics, chemistry, botany, and the like. Comparative anatomy ought to be absolutely abolished, although it would involve the putting back of such branches as zoölogy and botany to the students' early education in ordinary schools. He would also abolish Materia Medica. He could not understand why gentlemen who had to practice medicine should be obliged to learn all about drugs, and where they came from; they might just as well be required to learn all about cutlery because they used knives. If his views were adopted, there would be left for the four years' study the following nine subjects: physics applied to physiology, chemistry applied to physiology, physiology, anatomy, surgery, medicine, obstetrics, hygiene, and medical jurisprudence, which would be quite enough for the man's pursuit — and this course would not oblige a medical student to occupy his time with what would not be absolutely useful in his future life.

We condense the above account of Professor Huxley's remarks from a report in the *London Daily News*. As might have been expected, his strictures did not escape criticism. In a letter addressed to *The Lancet*, Dr. Parry attributed the deficiencies of the students in the examination on physiology to the method of examining adopted by Professor Huxley and his colleagues, complaining that the questions asked were too hard. This charge Professor Huxley at once rebutted by facts drawn from the official reports of the examinations. He challenges Dr. Parry to point out a single question in the papers given to the candidates which any one acquainted with the "fundamental principles" of physiology ought not to be able to answer. *Scientific Opinion*, in summing up the results of the discussion, decides that Professor Huxley's position has not been successfully assailed, and adds the following remarks, which will serve to show how the instruction in this department compares with that in our own medical schools: —

"But, leaving aside altogether the respective opinions of the two disputants, we would ask the question, Is physiology properly taught in medical schools generally? We doubt not that in some of the larger hospitals and colleges much attention is

directed to those facts and phenomena in practical physiology on which medicine itself is so firmly based. But is it not the case that in others, a few antique diagrams, preposterously unnatural models, utter absence of anything like real demonstration, and unnecessary dwelling on speculations and effete hypotheses, constitute the whole teaching of the subject of physiology? How many lecturers are there in London even, who demonstrate the circulation of the blood, or show the passage of the chyle along the lacteals, or make their students familiar with the normal heart and lung sounds, or with the difference between the anterior and posterior roots of the spinal nerves, or show the action of constant galvanic currents as compared with inductive ones, or familiarize their pupils with the result of section of the spinal cord at different points? We should like, indeed, to know. No doubt, numerous lectures on the cell theory are given; 'reflex action,' as an hypothesis, is adequately dwelt on; the relative claims of Servetus and Cæsalpinus to the discovery of the circulation are disposed of, and no end of text-book quotations are indulged in.

"This is unquestionable; but it is not teaching physiology as it ought to be taught; and as it is the system usually followed in nine cases out of ten in this country, Professor Huxley was perfectly justified in pointing it out, and passing the severest censure upon it. That Professor Huxley's view is right we do not for a moment doubt, and we thank him heartily for the courage and candor with which he has exposed a system, not only detrimental to the advance of abstract science, but most pernicious in its influence on the present generation of medical men, since it cultivates a tendency to accept the assertions of books rather than to observe the phenomena of disease."

STATISTICS OF HYDROPHOBIA.

The French Secretary of the Interior has communicated to the Academy of Sciences in Paris an interesting report concerning all the cases of hydrophobia which were brought to the knowledge of his employés from 1863 to 1869. Of the one hundred departments into which France is divided, eight failed to send in their reports; in thirty departments no case of hydrophobia occurred; in the remaining forty-nine departments three hundred and twenty persons were bitten by mad dogs. In one hundred and twenty-nine cases the biting was followed by hydrophobia; in one hundred and twenty-three cases the bitten persons suffered no evil consequence; and nothing was known of the remaining sixty-eight. In every case, without any exception, where hydrophobia broke out, the patients died. Of the whole number bitten, only twenty-six were females. Two thirds of all persons who had been bitten were males between five and fifteen years of age. The numbers of mad dogs were very nearly equally divided through the four seasons. The number diminished somewhat during the hottest months. The officers succeeded in establishing the time when the hydrophobia broke out in one hundred and six cases. In seventy-three cases it broke out during the first two months after the bite, and the other cases were divided among the following six months, only two falling in the eighth month. The disease never lasted longer than four days, and almost all the patients died on the second day. Of all the remedies employed after a person was bitten by a mad dog, the burning of the wound proved the only one which was followed by good results; of one hundred and thirty-four persons whose wounds were burned, ninety-two remained without evil consequences, whilst the same was the case with only ten of sixty-six whose wounds were not burned. The sucking of the wounds, or their treatment with ammonia immediately after the persons were bitten, proved salutary also in many cases, but cauterization was by far the safest means of all.

A SPECIFIC IN ERYSIPELAS.

In presenting a case of facial erysipelas before the University Hospital clinical service last week, Dr. J. E. Garretson remarked, that in his practice of the past five years he had met with no case of erysipelas which had not readily and instantly yielded to the local application of the muriated tincture of iron, tincture of cinchona, and sulphate of quinine. The case before him, he remarked, while threatening and angry looking, would, he felt convinced, so surely succumb, that he should give the patient the prescription and send her to her home, not to return for three days. Without attempting to enter into any special discussion of the variety of causes thought to influence this condition, Dr. Garretson said he felt sure that this peculiar inflammation had a basial irritant as specific in its character as that of small-pox, typhoid fever, or the ague, and that as, in this latter disease, we had found an antagonist in quinine, and that of typhoid fever not unlikely in hydrochloric acid, so in this morbid inflammation he trusted it was found in the combination alluded to. As, said the lecturer, every effect is from a cause so rational as to abort effects by removal of causes. He was not, he said, prepared to deny the existence of specifics; it was common sense, rather, to believe in them. Everything in physics exhibited and demonstrated the existence of antagonisms. He thought some of the members of the class would, most likely, live to see the day when the intelligence of this or the coming century might make even cancer a disease no longer to be dreaded. Without doubt this cachexia had a cause. Why should not continued investigations discover this cause? and if discovered, there was nothing at all improbable, certainly, in the supposition that it was capable of being antagonized. "Belladonna," he said, "would antagonize opium; yet it has been only a short time since we knew so important a fact; and hundreds, perhaps thousands, have died, simply because they had the misfortune to be born before the medical mind knew of such an antagonism."

The following cases which, within two weeks back, had been presented in his practice, were noted by Dr. G.:—

Case I. — Very old man; erysipelas of hand and arm attendant on an operation performed on one of the fingers three weeks before; parts heavily engorged and indurated, the finger sinking easily into the cushion-like mass. From fear, the patient had denied himself applying for assistance until the inflammation had been four days in progress. The whole arm presented the peculiar glisten, particularly that part just below the elbow, where an abscess was evidently forming. The combination, as usually prescribed, was directed.

℞. Tinct. ferri chlor.
Tinct. cinchonæ . . . f℥ij.
Quiniæ sulph. . . . gr. xxx.
Aquæ . . . . . . f℥iss. M.

This was to be applied by means of a brush four times a day.

Second day, blush all gone; opened the abscess; case well in a few days.

Case II. — Young professional gentleman; lacerated wound of ring finger; whole hand and lower portion of the fore-arm erysipelatous; fingers thrust widely apart by the swelling; back of hand a soft cushioning mass; few cases appear more threatening. No constitutional treatment; mixture applied as in the first instance, and hand enveloped in a poultice of flaxseed; next day the specific character of the inflammation had entirely disappeared. The treatment of this case was continued on general principles for five days, when the patient was in condition to be dismissed.

Case III. — Mill-boy from the country; erysipelas of leg; three days in progress. The father of this lad presented him in great anxiety, having during the summer of last year lost a son with an erysipelas which commenced in a similar location. In the boy presented for treatment there was no wound or traumatic injury of the part affected. At 5 o'clock on one evening the mixture was applied; by the next, the case seemed and remained entirely cured.

Dr. Garretson said, if necessary, he could readily occupy the entire hour in an enumeration of cases, both of cutaneous and phlegmonous varieties, which had proved to him the good service capable of being performed by this application. He said he desired, however, not to be understood as advocating the combination as specific in an ordinary acceptation of that term; the intelligence of the class would well enough recognize that only one of many indications which might be present was proposed to be met; namely, the destruction of the specificity of the inflammation; this is the lecturer likened to an injury which might be done by a musk-rat to a river bank, saying, that while the destruction of the rat would be specific treatment, there was yet a hole left to fill up. — *Medical and Surgical Reporter.*

Dr. Letheby, in an article on the water supply of London, states that water of moderate hardness, like that used in London, Paris, Vienna, and some other European cities, is always to be preferred to that which is entirely soft, as being best suited for domestic purposes, on account of being brighter to the eye and more agreeable to the taste. He also makes the singular announcement that the French authorities are so well satisfied of the superiority of hard water, that they pass by that of the sandy plains, near Paris, and go far away to the chalk hills of Champagne, where they find water even harder than that of London; giving as a reason for the preference that more of the conscripts from the soft-water districts are rejected, on account of the want of strength of muscle, than from the hard-water districts, from which they conclude that the calcareous matter is favorable to the formation of the tissues.

Dr. Letheby further states that the mortality in England is greater, on an average, in places where soft water is used, other circumstances being equal, than where the water is hard; and it is suggested that the sparkling hard waters of the limestone districts are relished, not only because they are pleasant to the eye, but on account of some hygienic properties in the excess of carbonic acid they contain, and possibly because the percentage of lime acts medicinally on the system. The Doctor concludes by expressing his preference for the very slightly hard water of London over a softer quality, although reprehending the use of water containing an excess of mineral matters.

Quacks and Cancers.— The item relating to "carbonizing cancers" by a "new salt" of chromium, which appeared in the last Journal, was accidentally put among the "accepted" instead of the "rejected" matter for the paper, and thus got into type; and the mistake was overlooked in reading the proofs.

As the address labels for each number of the Journal are printed before the 18th of the preceding month, money for renewals received after that date cannot be credited on the labels until the next month. We will send a receipted bill to any one inclosing with his subscription a three-cent stamp for return postage.

ANOINTING IN DISEASE.

During the past eleven months Dr. Knaggs has been testing, with uniformly successful results, the value of a very simple method of treating such infantile complaints as atrophy, bronchitis, convulsions, diarrhœa, febrile disturbances generally, and indeed all disturbances of childhood which are accompanied by an unnatural state of the skin.

The treatment simply consists in smearing with salad oil the whole surface of the body, from the crown of the head to the tips of the fingers and toes, the process being repeated every twelve, six, or even four hours, according to the urgency of the case. Of course, the use of a long flannel gown or small blanket is obvious, and the fluid should be slightly warmed.

The application of oil, the author writes, possesses the following immense advantages over the ordinary warm bath: —

1. Skin-action is more completely and permanently restored.

2. The danger of reaction is avoided, for there is no sudden change of temperature; and moreover the sheet of oil protects the surface from atmospheric influences.

3. It acts as a fuel-food, not only preventing waste of tissue, but actually increasing the bulk of the little patient.

4. It does not depress, but, on the contrary, appears to exhilarate.

It will scarcely be credited by many that the formidable affections above mentioned will frequently yield to this treatment, or at any rate show signs of abatement, in from twenty minutes to twenty-four hours, but such is the case, though sometimes forty-eight or even seventy two hours will elapse before any decided signs of improvement occur. — *Lancet.*

FOREIGN NOTES.

A New Remedy for Intermittent Fever. — Dr. Lorinser, of Vienna, gives, in the *Wiener Medizinische Wochenschrift*, the results of a number of observations with regard to a new remedy for intermittent fever. The remedy is the tincture of the leaves of the *Eucalyptus globulus*, a plant of the natural order *Myrtaceæ*. In 1869 Dr. Lorinser made some experiments, the results of which he published; but he was brought to a stand-still by the want of a supply of the medicine. The plant has since been cultivated by Herr Lamatsch, an apothecary; and a sufficient quantity of tincture has been made from the leaves to supply a number of medical men in the districts of the Theiss and the Danube, and in the Banat.

The records of fifty-three cases of intermittent fever in which the eucalyptus was administered have been communicated to Dr. Lorinser. Of these, forty-three were completely cured; in five, there was relapse, in consequence of a failure of the supply of the eucalyptus, and quinine had to be employed; two of the cases were not true ague; in one case, neither the eucalyptus nor quinine cured; in one, the medicine (as well as other remedies) was vomited; and in one the patient would not allow the treatment to be continued. In eleven of the cases quinine had been used without effect; and nine of these were cured by the eucalyptus.

A Civic Sanitary Staff. — The authorities of Glasgow have organized the most complete "sanitary department" probably ever established as a permanent branch of municipal administration. The object aimed at is no less than to prevent disease — not only to wipe away the reproach which Glasgow has of late years been incurring from the mortality returns, but to render the town more clean and sweet to live in, to improve the habits and condition of the poor, and to secure more vigorous health and greater length of days to all. The "Sanitary Inspection Service" consists of a chief officer, five district inspectors, and thirty ordinary nuisance inspectors, each of whom has a section of one of the five districts into which the city has been divided under his charge.

Ice in Chloroform Accidents. — Dr. Baillie, Surgeon to the Calcutta Native Hospital, states in the *Indian Medical Gazette*, that in cases of syncope from inhalation of too large a quantity of chloroform, there is no means upon which he should more rely to restore the movements of respiration, than the introduction of a *good sized lump* of ice into the rectum. This is much more easily effected than one would suppose; a little pressure with the ice being made over the sphincter causes it to relax, and the ice slips in, followed almost instantaneously by a prolonged inspiration, the precursor of natural breathing, and restoration of the heart's action. This measure, but with a *small* bit of ice, would doubtless, answer equally well with still-born children.

Concerning Opium. — M. Garnier, a member of the French Cambodian expedition, states that in China the taste for opium is by no means confined to the human race. Pigs and horses thrive upon poppy flowers, and when deprived of their favorite food languish and die. At a town in Zunnan rats used to resort in large numbers to an opium factory, in order to inhale the fumes from the coppers; and after the town had been sacked by the Panthays, the ruins of the building were still haunted by the animals.

The *Pall Mall Gazette* thinks that a good deal of nonsense is talked about the fearful consequences of opium-eating. In moderation opium is an excellent stimulant, and this is well known to the hundreds of literary and professional men who could hardly get through their labors without its help. The stereotyped emaciated opium-eater is one of the *bogies* used by well-intentioned but ignorant people, and is, like the hopeless drunkard, the exceptional instance in a large class.

An English journal recently asserted that opium is put into Manila cigars. In reply to this, an old resident of Manila remarks that "those who entertain this absurd opinion can have but little idea of the cheapness of tobacco here and the high value of opium: it would never pay to mix the drug, even in small quantities, with our excellent tobacco, which certainly needs no such addition."

The History of Hygiene in England. — In an address to the students of St. Mary's Hospital, a few weeks ago, Dr. Lyon Playfair gave some curious historical illustrations of the origin of hygiene in England. If his view of the matter is correct, the study of sanitary science arose from a singular accident. The Court and Parliament were at Oxford, which had been recently drained, and the citizens had removed all accumulation of filth and garbage from the streets, lest they should offend the nostrils of their distinguished guests. The plague was raging at the time, and Oxford was the only place which enjoyed an immunity from it. Cause and effect were for the first time connected in the public mind, which was thus enlightened for the first time as to the nature of what we now call pythogenic, or filth-born maladies. Prior to that, the measures recommended by the council of the physicians of Paris for the arrest of the plague were: That if a shower of rain fell during the day a spoonful of treacle should be taken, and that fat people should not sit in the sun. Michelet declares that for several centuries during which filth reigned supreme, not a man, woman, or child in Europe took a bath voluntarily and out of a desire for cleanliness. Out of this chronic and wide-spread filth arose the black death, the plague, the sweating sickness, and other pestilences, the consequences of bad hygienic conditions.

A Singular Experiment. — One of Dr. Richardson's last course of lectures on experimental medicine was remarkable for an experiment, which appears to show that there is a direct and almost immediate passage of substances in the gaseous form through all the tissues of the body, and especially through the coats of veins. He introduced a fine tube through the nostril of a rabbit into the cranial cavity. Air, or carbonic acid gas, pumped through this tube, instantly made its appearance in the right cavities of the heart. The carbonic acid darkened the blood and stopped the systolic action. Atmospheric air rendered the blood of the right side arterial, and restored the systole.

VALUABLE FORMULÆ.

Croup. — The *Chicago Medical Times* says that the following has the most marked effect in relieving this distressing complaint in its common form: —

R.	Oil Stillingia	gtt. x.
	Oil Lobelia	gtt. x.
	Diluted Spirits	oz. j. M.

One to ten drops in a little mucilage or syrup — or on sugar — to be given every fifteen or twenty minutes, until the paroxysm passes off, which it usually does very soon.

We have known many severe cases also to be relieved by simple warm water, given in teaspoonful doses every five minutes or so, until nausea was produced, and accompanied with hot packs around the throat.

The simple syrup of Lobelia, for domestic use, proves much more efficacious than the old fashioned Hive Syrup of the dispensatories. A very good way for making it quickly, is: —

R.	Tinct. Lobelia	oz. j.
	Simple Syrup	oz. iij. M.

Dose, half a teaspoonful to a teaspoonful every twenty minutes until relief is obtained. For office use, fluid extract of Lobelia, half an ounce, can be substituted for the tincture.

TOOTHACHE TINCTURES.

1. *Tincture of Pellitory.*

Take of Pellitory root (bruised). . .	1 ounce,
Alcohol	½ pint;

digest a week, with frequent agitation, then express the tincture, and, after repose, decant and filter it. Excellent as "toothache drops;" also, diluted, as a mouth-wash in toothache and face-ache.

2. Take of Tincture of opium .	2 fl. drachms,
Ether	4 "
Oil of cloves . . .	½ "

mix, with agitation, and shake it each time before use. The product is a favorite form of toothache drops with many persons, and represents the composition of several odontalgic nostrums.

3. Take of Creosote. . . .	1 drachm,
Chloroform . . .	2 "
Alcohol. . . .	3 fluid drachms;

mix, etc., as the last. Very serviceable in toothache arising from caries.

4. *Dr. Collier's.*

Take of Pellitory (bruised small) .	2 drachms,
Camphor	1½ "
Opium (powdered) . . .	½ "
Oil of cloves.	1 fluid drm.
Alcohol	½ pint;

digest a week, as the last. It must not be swallowed.

5. *Vicat's "Anodyne Odontalgique."*

Take of Powdered opium . .	1 drm. (Troy).
Powdered camphor. .	½ "
Ammoniated alcohol (caustic)	¾ fluid ounce,
Alcohol	1½ "

digest in a stoppered bottle, with agitation, for some days, and, after repose, decant the clear portion. Used as "drops" in toothache, in which it is often very serviceable, particularly when it arises from caries; also as a lotion in face-ache, and to the temples and forehead in headache. — *Druggists' Circular.*

Boston Journal of Chemistry.

OLUME V. BOSTON, OCTOBER, 1870. NUMBER 4.

Familiar Science.

THE CONSUMPTION OF GUNPOWDER.

It is generally supposed that in time of war ere is a vast increase in the consumption of npowder; but this is not the case. It is a rious fact that the arts of peace require a ich larger use of the explosive than the arts war, and that consequently France and ermany will burn *less* gunpowder from month month during the contest than they otherse would if peace had continued. Even in severest and most protracted battles comratively *little* is burned. One of the owners a large powder-mill in this State informed us ently, that he could make at his establishnt before breakfast any morning all the pow- that was consumed at Gettysburg. Ben tler stored more powder in his foolish "bomb p," which he exploded against Fort Fisher North Carolina, than was used in some of our st important battles. War takes from mines, nufactories, farms, etc., tens of thousands of n who are constantly engaged in consuming npowder for various purposes. In the army y pass months, perhaps years, in idleness, and occasion is afforded for its use except in utes, etc., so that they actually consume less service than out. There was during our ntest, especially during the first part of it, reased activity among powder makers, and materials of gunpowder rose in price, but a y small part of that manufactured was ever sumed. The Government has now on hand, its magazines and arsenals, prodigious quanti; enough probably to carry us through two h wars as the last. It may be further obved that probably not one ounce of gunpow in twenty used in battle does any execu. Its explosion serves to increase the oise and confusion," but comparatively very are hurt through its agency.

HAT SHALL WE USE FOR WATER-PIPES?

We are certain that the discussion of no subt can be of more general interest to our ders than that relating to the nature and ety of the different kinds of pipes which are d for conducting water to the culinary departnts of dwellings. Great anxiety has always n manifested, by housekeepers and others, arding the safety of the conduit pipes in genl use, whether composed of lead or of other tals. It is important that this subject should fairly and intelligently discussed, in order t the extent of the danger may be clearly lerstood, and also that the utility and economy different kinds of pipes may be known. ile it is important that all real sources of iger should be pointed out, it is also desira that groundless or unnecessary fears should allayed. We are happy to present to our readers, in plain language, the results of several years' observation and experiment upon the different kinds of water-pipes.

LEAD PIPES.

Lead is the metal by far the most largely employed for service water-pipes, and it certainly is the cheapest and most convenient material of which to construct them. It is soft, ductile, easily and readily put in position, and seldom gives trouble by leakage. It is a pity that a metal so well adapted to our wants should be liable to be dissolved by the water brought in contact with it, and that the metal and its salts should so disturb the vital functions as to engender disease and destroy life. And yet, we cannot help remarking, how slight is the danger from the use of lead water-pipes. Millions of pounds of it lie buried in the earth, and through it water is flowing to thousands of families, and yet comparatively a small number suffer from its influence. A large proportion of the waters of this country, that are suited to culinary purposes, will pass through lead pipes under *ordinary conditions*, and remain uncontaminated. During the past quarter of a century, we have studied diligently this matter of the action of different waters upon lead, we have made hundreds of analyses, and have found but few from ponds, lakes, and open reservoirs that do not contain elements which exert a *protective* influence upon the surface of the metal. The first chemical action of water upon lead is usually that of oxidation. The oxygen, which enters into combination with the metal, comes from the air always present in water, or possibly it may come from the water itself through chemical decomposition, the result of galvanic action. The oxide of lead is a soluble compound, and quite poisonous. If the results of the contact of water with lead were to stop here, not a family could use leaden pipes with impunity. The oxide would continue to form as fast as it was washed away and dissolved by the current, and shortly the whole structure would be destroyed. But most waters contain, or hold in solution, another element, carbonic acid, which readily combines with the oxide, and forms a new salt. This is the carbonate of lead, and fortunately is *insoluble*. The first action, then, of most waters upon lead is to form upon the surface a coating of the white oxide of lead; the second action is to change this dangerous soluble oxide into a hard insoluble carbonate, and this, adhering to the whole interior surface of leaden pipes, prevents further contact of the water with the metal, and all decomposition ceases. This is a plain statement of the way in which lead is usually acted upon by water; and if there were no disturbing agencies to come in and interfere with these results, we should hardly require safer or better water-pipes than those constructed of lead.

It sometimes happens that well and spring waters contain other agents which interfere with the chemical changes we have described. Many wells in the Northern States are fed by springs which percolate through or over beds of rocks charged with iron pyrites, or sulphuret of iron. This mineral is usually found in the form of little cubes, very hard and dense, and having a golden yellow color. These cubes are often supposed to be true *gold* by well-diggers. We receive a carefully done-up package of this mineral as often as once a week during the year, sent to us for chemical analysis, the finder believing he has discovered a gold mine. We are always sorry to be compelled to furnish results which demolish the foundation upon which rest "great expectations." Waters brought in contact with such minerals are often impregnated with an offensive gas (sulphuretted hydrogen, or sulphydric acid) and the taste is unpleasant. Their action upon leaden pipes is of an unfavorable nature, producing sometimes rapid decomposition. We have not sufficiently investigated the nature of this action to be able accurately to define it; but it is certain it occurs, and leaden pipes should not be employed to conduct such waters. Organic matter from vaults and cesspools frequently finds its way into wells, and changes the character of waters, so that they become dangerous in their influence upon lead. Some waters are decidedly alkaline, and thus the action of carbonic acid upon lead oxide is neutralized, and it remains in solution.

The nature of the action of water upon lead is changed from local causes, operating within the pipes themselves. Lime, leaves, and other substances, which may be deposited in the angles or bends of pipes, will modify the chemical changes, so as to render an otherwise safe pipe very unsafe. The twisting and bending of pipes, when placed in position, disturb the crystalline structure of the metal, and give rise to electrical currents, which promote its solution in water. Well-waters and spring-waters are usually more unsuited to lead conduction than those of ponds and rivers.

As service-pipes for aqueducts, lead pipes will, under ordinary conditions, deliver water free from lead contamination. In a city or town supply, where the general influence of the waters is protective, as described above, there will be *local causes* operating, through the agency of which *some* families will suffer from lead poison. No city or large town can introduce lead service-pipes into its aqueduct system, with entire exemption from danger. It is not enough to learn the *general* influence of aqueduct waters, as thereby people are misled; we must know the character of the water which flows into each *separate* dwelling, if we would have knowledge of its *exact* influence. If each water-taker in a city could have the water received carefully tested twice during the first year after it is introduced, he would learn

whether he is free from danger or not. If, after this period, the water flows pure, no anxiety need be felt. It is perhaps impracticable to have chemical analysis of waters made upon so extensive a scale, but it is the only way in which there can be perfect exemption from cases of lead poisoning in cities. In a majority of wells, lead conducting pipes can be used with safety; but since without analysis it is impossible for housekeepers to know *when* the conditions are unfavorable, it will be better to employ some other kind of pipe. It may be said here that we have used water in our own dwelling for twenty years, which passes through leaden service-pipes from the iron mains of the city of Haverhill aqueduct. Not a trace of lead has been found in the water since the first month after its introduction. If we did not *know* that we are free from agencies causing local decomposition, we should remove the pipes at once.

TIN-LINED LEAD PIPES.

To obviate the danger incident to lead pipes, an inventor in New York conceived the idea of lining the interior of such with tin. These pipes are called "*tin-lined lead pipes.*" They are constructed of a thick outside pipe of lead, while another thin one, of tin, is drawn through the interior and rests in contact with it, forming a lining. This idea is such as would quite naturally suggest itself to any one; and ingenious mechanics or inventors, unacquainted with the electro-chemical relationship of metals, would seize hold of it as a most important discovery. They would not know that tin by itself is often more readily attacked and dissolved by water than lead, and that, when placed in association with lead, if any water contact is made between the tin and lead, both metals are dissolved with increased rapidity. We have heretofore unreservedly expressed our dissatisfaction with this pipe; and our views are supported by some *practical* scientific men, whose opinions are certainly worth more than those of a whole army of gentlemen who devote their lives simply to performing illustrative chemical experiments before classes in colleges. Besides this, we have had opportunity of examining specimens of the pipe which have been used for different periods of time, and we have found results which fully confirmed our opinions. In regard to this pipe, we do not assert that in every case, or in a majority of cases, where it is used it is positively dangerous. If the pipe is perfectly covered with tin throughout its entire surface, and if it is placed in contact with the waters of such wells or aqueducts as do not readily act upon tin, it will serve a good purpose for many years. What housekeepers require in a water-pipe is *not* one which *may become dangerous under conditions liable to occur*, but one which *is safe under all possible conditions. The tin-lined lead pipe is not of this character.*

TIN PIPE.

Pure "block-tin," so called, supplies a good metal from which to construct water-pipes. As noticed above, it has the disadvantage of being readily acted upon by some waters; but this is purely an economical matter, as the salts of tin are not specially poisonous, and no harm can result from its solution in water. Block-tin pipes are quite expensive; but this is a small matter to many, and we recommend the use of tin pipes in cases where cost is not regarded. Of course, there are many who cannot afford them, and a cheaper and equally safe water-pipe is needed. Those who seek a cheaper pipe must not be deceived by the clean, attractive appearance of the

GALVANIZED IRON PIPE.

Since we called special attention to the objectional nature of this pipe, in the August number of the JOURNAL, a flood of correspondence has poured in upon us; and we are no less surprised at the sad want of correct information manifested by the writers, than at the extent to which this pipe has been introduced. Incredible as it may appear to those who understand its chemical nature, it is evident that it has come into quite common use, and that thousands of yards of it are put down every day, for the conveyance of water for household use. Several of our correspondents ask if we are not mistaken in our views regarding the dangerous character of galvanized pipe, and one *doctor* remarks that the salts of zinc are *not* poisonous, as he uses them freely in medicine. Indeed! So we suppose he employs also the salts of *lead* in medicine. Zinc salts and lead salts may be very good remedial agents, but we had rather be excused from using them freely as condiments in our daily food. Another says that he has taken up his pipe laid down two years ago, and he finds it "all right." By the same mail came half a dozen letters describing the galvanized pipes put in position a few months ago, which were *not* found to be "all right."

Iron pipes are "galvanized," by immersing the common gas-pipes in hydrochloric acid, and then immediately placing them in a bath of melted zinc. The zinc amalgamates with the surface of the iron, forming a superficial covering of the metal. This is a *very cheap* process, and was originally adopted with the view of preventing gas-pipes from rusting in damp places. Such pipes were never designed to be used for the conveyance of water, even by the manufacturers; and how any one ever ventured to use them for that purpose is a matter not easily understood by us. Zinc is a coarse, cheap metal, easily oxidized or corroded by weak acids, and when thus acted upon, forms salts, which are harmful to the economy. Who ever heard of zinc being recommended by a reputable chemist as a suitable metal from which to construct water-pipes? And yet pipes composed entirely of zinc would be less readily acted upon by water than the coating of the metal when deposited upon iron. The thicker this coating, the more dangerous it becomes, as the longer time is consumed in removing it, and the larger the quantity of salts produced. It may be further observed, that if the salts of zinc were not injurious, galvanized iron pipe should not be used for water from economical considerations. It costs more than plain iron pipe, oxidizes more readily so long as a trace of the zinc remains, and therefore has a less money value. Used for dry gas, above ground, iron pipes coated with zinc may have some advantage over the uncoated, but they are, after all, insignificant. We now pass to the consideration of plain iron pipes.

NOTE.— Our article has become unexpectedly long, and as we wish to speak of iron, brass, gutta-percha, clay, and other kinds of pipes, we will defer the remainder until the next number of the JOURNAL.

THE STARRY UNIVERSE.

MR. R. A. PROCTOR, the well-known English astronomer, has lately delivered an interesting lecture before the Royal Institution "on star grouping, star-drift, and star-mist." The closing paragraphs, which may serve as a summary of the lecture, are as follows:—

"It remains that I should exhibit the general results to which I have been led. It has seemed to many that my views tend largely to diminish our estimate of the extent of the sidereal system. The exact reverse is the case. According to accepted views, there lie within the range of our most powerful telescopes millions of millions of suns. According to mine, the primary suns within the range of our telescopes must be counted by tens of thousands, or by hundreds of thousands at the outside. What does this diminution of numbers imply, but that the space separating sun from sun is enormously greater than accepted theories would permit? And this increase implies an enormous increase in the estimate we are to form of the vital energies of individual suns. For the vitality of a sun, if one may be permitted the expression, is measured not merely by the amount of matter over which it exercises control, but by the extent of space within which that matter is distributed. Take an orb a thousand times vaster than our sun, and spread over its surface an amount of matter exceeding a thousandfold the combined mass of all the planets of the solar system:— so far as living force is concerned, the result is — *nil.* But distribute that matter throughout a vast space all round the orb:— that orb becomes at once fit to be the centre of a host of dependent worlds. Again, according to accepted theories, when the astronomer has succeeded in resolving the milky light of a portion of the galaxy into stars, he has, in that direction at any rate, reached the limits of the sidereal system. According to my views, what he has really done has been but to analyze a definite aggregation of stars, a mere corner of that great system. Yet once more, according to accepted views, thousands and thousands of galaxies, external to the sidereal system, can be seen with powerful telescopes. If I am right, the external star-systems lie far beyond the reach of the most powerful telescope man has yet been able to construct, insomuch that perchance the nearest of the outlying galaxies may lie a million times beyond the range even of the mighty mirror of the great Rosse telescope.

But this is little. Wonderful as is the extent of the sidereal system as thus viewed, even more wonderful is its infinite variety. We know how largely modern discoveries have increased our estimate of the complexity of the planetary system. Where the ancients recognized but a few planets, we now see, besides the planets, the families of satellites; we see the rings of Saturn, in which minute satellites must be as the sands on the sea-shore for multitude; the wonderful zone of asteroids; myriads on myriads of comets; millions on millions of meteor-systems, gathering more and more richly around the sun, until in his neighborhood they form the crown of glory which bursts into view when he is totally eclipsed. But wonderful as is the variety seen within the planetary system, the variety within the sidereal system is infinitely more amazing. Besides the single suns, there are groups and systems and streams of primary suns; there are whole galaxies of minor orbs; there are clustering stellar aggregations, showing every variety of richness, of figure, and of distribution; there are all the various forms of nebulæ, resolvable and irresolvable, circular, elliptical, and spiral; and lastly, there are irregular masses of luminous gas, clinging in fantastic convolutions around stars and star-systems. Nor is it unsafe to assert that other forms

nd varieties of structure will yet be discovered, or hat hundreds more exist which we may never hope to recognize.

But lastly, even more wonderful than the infinite ariety of the sidereal system is its amazing vitality. nstead of millions of inert masses, we see the whole eavens instinct with energy, — astir with busy life. The great masses of luminous vapor, though occupying countless millions of cubic miles of space, are moved by unknown forces like clouds before the ummer breeze; star-mist is condensing into clusters; star-clusters are forming into suns; streams nd clusters of minor orbs are swayed by unknown ctive energies; and primary suns, singly or in systems, are pursuing their stately path through space, ejoicing as giants to run their course, extending on l sides the mighty arm of their attraction, gathering from ever new regions of space supplies of motive energy, to be transformed into the various forms f force, — light, and heat, and electricity, — and istributed in lavish abundance to the worlds which rcle round them.

Truly may I say, in conclusion, that whether we gard its vast extent, or its infinite variety, or the mazing vitality which pervades its every portion, the dereal system is, of all the subjects man can study, e most imposing and the most stupendous. It is a book full of mighty problems, — of problems hich are as yet almost untouched by man, of problems which it might seem hopeless for him to attempt to solve. But those problems are given to m for solution, and he *will* solve them, whenever dares attempt to decipher aright the records of at wondrous volume.

CHEMICAL INTENSITY OF SUNLIGHT.

FOR many years past Professor Roscoe, of Manchester, Eng., has devoted much attention to the easurement of the chemical intensity of light at fferent parts of the earth's surface and under varying conditions. At the outset these laborious and portant researches were made in conjunction with ofessor Bunsen, of Heidelberg; subsequently the tter was taken up in England, and instruments structed according to the plan of Professors nsen and Roscoe were set to work at Kew Obvatory, where the registration of the chemical ensity of daylight has been chiefly carried on hin the last few years.

Very recently Professor Roscoe and Mr. Thorpe e made a new series of determinations in the tude of Lisbon, and have arrived at the following y interesting general results, which confirm those viously obtained by one of the authors: —

It is found that the intensity of diffused light of sky — not that reflected from clouds — is proptional within certain limits to that of the sun lf. When the altitude of the sun is less than degrees above the horizon the chemical insity of its light is practically nothing, while that ected from the sky reaches a very appreciable ntity.

Again: the chemical intensity of the solar light ound steadily and regularly to increase with the 's altitude, until the maximum is reached when meridian is crossed. The reason for this obvisly is that, as our great luminary pursues his arent upward course in the heavens, his rays e to penetrate a less extent of the earth's abent atmosphere, until, at the zenith, the light to pierce a layer of minimum thickness of this orbent envelope. As the sun declines after n, the same gradual loss of actinic power in its t is observed. It is found that, though the litions of the atmosphere may vary, this increase diminution of the intensity of the solar light is tly proportional to the altitude of the sun.

One of the consequences of this law is of the pest interest to photographers, more especially to those living under a cloudless sky, as it would only be necessary to determine the time of exposure of a print at one period of the day, and Professor Roscoe's table would then supply the necessary information as to exposure at any other hour while the sun was more than ten degrees above the horizon.

DIFFUSION.

SOME very elegant and simple methods of exhibiting the phenomena of diffusion are given by Herr Merz, in a recent number of the *Journal für Praktische Chemie.* A portion of the shell of an egg having been removed by the action of hydrochloric acid, leaving the membrane exposed, the egg is to be suspended in water from the arm of a balance, a counterpoise being placed in the opposite scale. In about half an hour the weight of the egg has sensibly increased, as the position of the balance-beam will show, in consequence of the passage of water through the membrane. If, now, alcohol be substituted for the water, and the weights readjusted so as to bring the beam horizontal, it will soon commence to move in the opposite direction, showing that the egg has become lighter by the diffusion of water into the alcohol. The diffusion of vapor may be exhibited by tying a diaphragm of india-rubber — a portion of a small toy balloon will answer the purpose — over the mouth of a funnel, the other end being in communication, by means of an elastic tube, with a vessel of water. The funnel being inverted over a dish containing ether, which, however, the diaphragm is not to touch, the vapor of this fluid will pass rapidly into the funnel, the air being observed to escape in bubbles in the water at the small end. Remove now the vessel of ether, and the operation will be reversed, the vapor passing through the diaphragm into the atmosphere. In order to fill the vacuum thus created, the water will rise in the tube, the lower part of which should be of glass to render this apparent, and the diaphragm will be curved inward. These experiments are particularly instructive, and are within reach of every one. The balance may be extemporized by means of a light bar of wood.

SINGULAR OPTICAL PHENOMENON.

NOT long ago, on a day when the sea was calm and the sky was clear, the water flowing from the "A. B. C." Works for the purification of sewage, at Hastings, England, appeared like a dark current amid the general azure of the salt water. Most people thought that there was some trouble with the machinery at the works, and that the sewage was flowing into the sea in its original state of impurity. Even the parties who were conducting the works became perplexed. A boat put off, in order to investigate the state of affairs, and samples were taken from the black stream as well as from "the bright, blue sea." On examination it was found that the black water was the clearer. The fact was that the same phenomenon had been repeatedly witnessed before, but never carefully investigated. The eye of an intelligent observer would often perceive — particularly on such a day as that to which we now refer — that the sea on the verge of the horizon was of a deep indigo blue, tending to blackness, whereas near the shore the tint was much paler. The gradation of tints between the distant water and that which lay close to the shore diminished the effect of contrast. But the effluent water from the sewage works brought the deep blue into the midst of the light blue, so that the former looked most suspiciously dark. The sea near the shore held particles of sand in suspension. These particles reflected the light, and gave the water a paler tint, in consequence of their own sandy hue. Far out, the sea was tolerably clear from this suspended matter, and therefore the pale reflection was absent. The more free from mechanical impurity, the less able was the water to reflect light. Hence an apparent darkness. Every one knows how a dark room is often lit up by a passing cloud, simply because the cloud reflects more light than the sky. So in like manner cloudy water may at a distance look brighter than clear water. Thus, the clear water resulting from the "A. B. C." process was unable to reflect so much light as the sandy fluid into which it was ejected, and consequently the clear stream appeared comparatively black. To the fishes gazing upwards the effect must have been reversed, the clear stream transmitting a greater proportion of light than the sandy sea.

MECHANICAL EFFECTS OF MAGNETIZATION.

THE following is from a recent lecture by Professor Tyndall: —

"At the moment when the current passes through the coil surrounding the electro-magnet, a clink is heard emanating from the body of the iron, and at the moment the current ceases a clink is also heard. In fact, the acts of magnetization and demagnetization so stir the particles of the magnetized body that they, in their turn, can stir the air and send sonorous impulses to our auditory nerves. These sounds occur at the moment of magnetization, and at the moment when magnetization ceases; hence, if a means be devised of making and breaking, in quick succession, the circuit through which the current flows, we shall obtain an equally quick succession of sounds. I do this by means of a contact-breaker which belongs to a Ruhmkorff's induction coil. A thin bar of iron stretches from one of the bridges of this monochord to the other. This bar is placed in a glass tube, which is surrounded by copper wire. The contact-breaker is placed in a distant room, so that you cannot hear its noise. The current is now active, and every individual in this large assembly hears something between a dry crackle and a musical sound issuing from the bar in consequence of its successive magnetization and demagnetization."

The Arts.

HYDROGEN GAS: AN IMPORTANT DISCOVERY.

FOR a score of years we have industriously experimented with the view of discovering a practicable and cheap method of preparing *hydrogen gas.* This problem is undoubtedly one of the most important that can engage the attention of chemists, and therefore immense sums have been expended in attempts to solve it. We have sought to eliminate hydrogen from all conceivable sources, and by all conceivable devices; but while we could obtain it in satisfactory *quantity,* the important element of *cost* would come in to disturb our practical results. As regards obtaining hydrogen by the decomposition of water or steam by heat or any direct methods, we became satisfied long ago that the idea was fallacious. The intense heat or force demanded to effect the separation of the hydrogen from the associated oxygen is equivalent in cost to the value of the product obtained, to say nothing of the wear and tear or destruction of the apparatus employed. No class of charlatans are more presumptuous and dangerous than those who infest cities, or travel over the country, selling

"patent-rights" to use or make "water-gas stoves," or patents for burning water or steam. Their schemes are often so ingenious and delusive, that men who have some reputation as chemists are deceived. A few years ago, an inventor in New York brought to this city a water-burning stove, and placed it on exhibition under the auspices and upon the recommendation of a gentleman who now serves as a *State Assayer*. The great Cunard steamships, according to his view, were to be sent across the ocean, the boilers heated by this water-gas, and all the world was to pay tribute to the new calorific device. Like the stick to all water-gas rockets, it came down tamely and ignobly to earth, but we have no doubt that other adventurers will pick it up, and start it skyward again.

We desire to call attention, however, to a new process for making hydrogen which, so far as we can see, is one of great promise. It is the invention of Messrs. Tessié du Motay and Maréchal, the French chemists who have been so successful in cheapening the production of oxygen by a process which has been fully described in the JOURNAL. They, indeed, obtain their hydrogen from water, but indirectly by the use of alkaline hydrates, decomposing them by means of carbon. When quicklime is "slacked," or acted upon by water, as in the process for making mortar, it becomes intensely hot, swells up, absorbs much water, and finally, on cooling, crumbles into a dry powder, which is the hydrate of lime. This hydrate Du Motay places in retorts along with charcoal, coke, pit coal, peat, or other substances rich in carbon, and heats them to a red heat. The hydrate of lime is decomposed, and by loss of water is converted into oxide of calcium; the water also is decomposed, its oxygen uniting with the carbon to form carbonic acid. The mixture of carbonic acid and hydrogen thus obtained is passed through water, which takes up the carbonic acid, and the pure hydrogen is then collected for use. The oxide of calcium produced by the decomposition of the hydrate of lime can be reconverted into hydrate, and thus used again and again. The whole process is as simple and easy as that for making carburetted hydrogen or illuminating gas. The hydrogen gas is generated without any special production of steam, and hence may be prepared without any other apparatus than the retorts themselves, and also the retorts remain uninjured.

If hydrogen can be thus obtained in copious quantity at small cost, it promises to bring about a complete revolution in the industrial and domestic concerns of the world. All the present modes of smelting, heating, cooking, etc., may be done away with at once. The era of no smoke, no dust, no ashes, no tugging at the coal-bin or wood-pile, comes in with the invention, and in the kitchen an important part of Bridget's duties is gone forever. If the process for obtaining hydrogen which we have described fulfils the expectations of its distinguished inventors, the gas before long will be manufactured in every city and town, and distributed to consumers in the same way as illuminating gas now is. It will be used for heating houses, cooking, generating steam, etc., instead of coal and wood. We hardly dare to expect so great and desirable an event as this; nevertheless there is ground for hope in Du Motay's process, and let us wait with becoming patience the full developments of so important a discovery.

A NEW TELESCOPE.

HAVING been engaged in telescopic observations, for the past eight or ten years, with instruments of various apertures, between $\frac{1}{2}$ and $3\frac{1}{4}$ inches, I thought that I would communicate to you the results of a few observations, which I lately made, with one of the new, improved, short-focus telescopes of $2\frac{1}{2}$ inches aperture, 23 inches focus, with a celestial eye-piece magnifying 45 diameters, constructed by Mr. R. B. Tolles. This telescope readily shows Polaris double; it appears as steady as Titan does in my 48-inch achromatic, with a power of 81. It shows very finely the four principal stars in the trapezium of Orion, also Mizar, Beta Cygni, and other superb double stars. The view it gives of the great nebula of Orion is magnificent. The elliptical nebula in Andromeda was well seen. Various clusters of stars in the milky way were exhibited in great splendor. Rigel I saw double, which I consider a pretty severe test. The planet Jupiter was a beautiful object, its oblate figure being so very apparent that one unaccustomed to telescopic observation would readily perceive it; the equatorial belts were shown very distinct and sharp; the satellites appeared round and very distinct, the difference in their size very apparent. Saturn is also a splendid object; the principal division in the ring is shown all round. I saw the inner dark ring, where it crosses the ball; also the equatorial belts and the shadow of the ball, on the ring; two satellites, with a glimpse of a third, that I am confident of.

The short focal length of this telescope I consider to be a great advantage, making it more portable, and much more easily directed to a celestial object. The instrument is mounted on a firm cast-iron tripod, with appliances for keeping it in position. It shows all the objects enumerated here far better than a similar power in my 48-inch glass, which has a clear aperture of $3\frac{1}{4}$ inches, and which I consider a good glass. Since making these observations I have had the loan of another telescope, made on the same principle, but with an object-glass only 1 inch in diameter, and 4 inches focal length, furnished with a pancratic erecting eye-piece, magnifying 24 times. Its performance is wonderful. It shows Saturn well, but with terrestial objects, its definition is superb. It is mounted on a universal joint, with a gimlet screw to fasten it to a tree, fence, etc.

I should have made a comparison between these two large instruments with the same eye-piece, but had no appliances convenient to fit the Tolles eyepiece on my instrument; but from my experience I consider the Tolles glass the superior instrument, the field being very dark, instead of gray, as in other instruments. I have never seen any small telescope perform equal to the $2\frac{1}{2}$ or 1 inch.

WILLIAM H. PHELPS.

MEMORANDA IN THE ARTS.

THE LAVATOJO. — Although the olive is the most important product of Italy, the means generally employed for extracting the oil are very imperfect, and until within the last five or six years, after the olives had been crushed by the peasants the husks were abandoned as worthless; but in a few places steam machinery has been introduced to turn to account the husks thrown away by the peasants as worthless, and which it is now known represent a considerable portion of the value of the oil crop. The process of extracting the oil from the husks by a *lavatojo* is very simple. The husks are placed in tubs, and worked with water by machinery until the water has carried off all the remaining oily matters which rise to the surface after the water has been allowed to remain still. The husks are then put in a stea press, which squeezes out all the moisture; and a ter they have gone through these different process the husks are used for fuel. The oil thus extract is used for the manufacture of soap.

ARTIFICIAL PRODUCTION OF ICE IN INDIA.— In many parts of India the natives dig shallow pi in such localities as are quite freely open to t sky and distant from trees. The pits are lined wi straw, and upon the straw are placed dishes (ma of a very porous earthenware) filled with wate During the calm and clear nights prevailing du ing the period from November to the end of Fe ruary, the water placed in the dishes freezes, yiel ing a solid cake of ice, while the temperature of t air is + 10°. Dr. Janssen has investigated th curious subject experimentally, and has found th the freezing is principally due to the radiation du ing the night; but the evaporation of the wate aided by the porosity of the earthenware employe is not to be overlooked at the same time.

AN IMPROVED PAVEMENT. — The Commissio ers of Sewers for the City of London are showi a worthy desire to solve the pavement problem, e pecially as to the value of asphalt. More than tw years since an admirable piece of granite paveme fixed by asphalt, instead of by lime and sand, w laid in Duke Street, Smithfield, and the experien gained there seems to prove it to be the be adapted to sustain the heavy and severe traffic the London streets. After two years of the roug est use, not a single stone has shown the slighte appearance of wear or displacement. A furth portion is now being laid down inside Temple Ba The merits of this asphalt pavement are, that gives clean streets in winter by preventing t pumping up of mud from between the stones, whi the old system favors, and also prevents dust summer by stopping up the source whence the du comes. The sewers will also be relieved of an im mense amount of solid *detritus* coming from thi source. Asphalt being impervious to water, the be will always keep dry and intact.

A NEW PROJECTILE FOR NAVAL USE. — Ca tain Ericsson announces that he has perfect a system of submarine attack by which he can d stroy the largest ironclads ever built. The resis ance of the water is so great that explosive proje tiles have always proved failures hitherto when d signed to strike below the water line. Capta Ericsson is confident that he has devised a proje tile which will overcome the difficulty caused by th resistance. It is an elongated shell, charged wi 300 lbs. of dynamite, and shot from a 15 inch gu at such an elevation as to enter the water near t hostile vessel, and strike the hull anywhere belo the water-line. It is fitted with a percussion ca which explodes upon very slight inpact against t hull, so that the velocity of the shell when it reach its destination need not be high. The gun is ca ried on a swift armored boat, protected by a turre Captain Ericsson is ready to fit out at his own co and risk a fast screw vessel with two 15 inch guns the kind described, if somebody else will furnish th ironclad to be experimented upon. He singles o the new British ironclad *Devastation* as one of th most splendid specimens of an armored war vess which can be produced, and challenges her to com out and encounter his torpedo.

POLISHING POWDER FOR GLASS, ETC. — Pro ably the best polishing powder for metals of mediu hardness and for glass would be that used by Lo Rosse for polishing the speculum of his large tel scope. He thus describes his method of prepari it: "I prepare the peroxide of iron by precipitatio with water of ammonia, from a pure dilute solutio of sulphate of iron. The precipitate is washe pressed in a screw-press till nearly dry, and expose to a heat, which, in the dark, appears a dull, lo

red. The only points of importance are that the sulphate of iron should be pure and the water of ammonia should be decidedly in excess, and that the heat should not exceed what I have described. The color will be a bright crimson, inclining to yellow. I have tried both potash and soda, pure, instead of water of ammonia, but after washing with some degree of care, the trace of the alkali still remained, and the peroxide was of an ochrey color, and did not polish properly."

Bleaching Wool. — A French patent, by M. Fregon, furnishes a novel process for bleaching wool and silk, for which until now we have had only the sulphurous acid method. A bath is made by dissolving 4 lbs. of oxalic acid and 4 lbs. of common salt in 200 quarts of water, and the goods to be bleached are left in this bath for an hour, after which they are drained and rinsed in soft water.

Agriculture.

THE ADULTERATION OF MILK.

It is so generally understood by consumers of milk in cities that they do not and cannot obtain the pure article, that they cease to manifest much anxiety regarding the matter, and receive what is brought to them by venders, without inquiry or examination. The venders understand this, and knowing how difficult it is to detect the fraud, they carry the attenuation to a point where the article ceases to exhibit even the physical characteristics of the lacteal fluid. Water is the great adulterating material, and this is mixed with milk in such large quantities by the New York dealers that the citizens are defrauded to the enormous amount of twelve thousand dollars a day, or *four millions of dollars* annually. In this city adulteration is not so flagrant, or extensive, yet the amount of water paid for by our citizens, at ten cents per quart, amounts to a very large sum yearly. We have frequently made analyses of specimens of milk sold in this city, and never, except in a single instance, have we found the adulterating material to be other than water. Nearly two years since an employee in our laboratory noticed in a milk vessel in use at his boarding-house an insoluble substance resting upon the bottom as a precipitate. A specimen of this was secured for chemical examination, and it was found to be the substance known as "whiting," an impure carbonate of lime. This was indeed a wholly factitious milk, a vile mixture, and such as we trust is seldom manufactured. Nearly all our large cities and towns appoint milk inspectors, whose duty it is to seize and cause to be analyzed all suspected specimens, and, if any are proved to be fraudulent, to prosecute the dealers. This has seemed in some degree to prevent adulteration, but it is very far from being a satisfactory protection. It is not a difficult matter to analyze milk, but it is a difficult point to decide positively that specimens have been tampered with by the addition of water. We have in our pastures a score of cows, and, upon examination of the milk furnished by each, we have not found that any two furnish it of precisely the same quality. We have cows supplying milk which would probably be condemned by Dr. Chandler, or other competent chemical examiners, as factitious. It is certain that the specific gravity cannot be relied on; neither can the general fact that true milk contains no more than 88 per cent. of water. Some cows furnish milk of such inferior quality that the amount of water exceeds 90 per cent. We need in our milk examinations a good and reliable test that will tell us when water has been purposely added, and also afford us positive knowledge regarding the quantity. If this test can be supplied, convictions for frauds will be easy, and the evil of adulteration can be speedily abated. Dr. A. E. Davies, Chemical Inspector of Milk in Manchester, England, states that he has found the specific gravity of the serum, or liquid portion of the milk, from which the caseine and fat have been removed by coagulating and straining, to be remarkably constant, and he proposes a test based upon this fact. The serum of genuine milk has a specific gravity of 1.026; now, by diluting this with various quantities of water, we may obtain a standard of comparison, which will show what quantity of water has been purposely added to any specimen of milk brought under examination. This is apparently an important suggestion, and we shall take early opportunity to submit it to practical experiment.

PEARS AND GRAPES.

We have fruited this year over thirty varieties of pears, and about as many varieties of grapes, and have carefully watched the growth and time of ripening of the fruit from both trees and vines. In common with all other kinds of fruit, they have suffered greatly this season in New England from drought. This has been very severe, and we have reason to fear that permanent injury has come to our trees. Pears and grapes have ripened prematurely, and in many cases imperfectly, and the quality of the fruit is affected. We can, however, judge in a measure of the comparative merits of the different varieties, and, in the light of past experience, are able to name those best adapted to our climate. In New England we must make our list of really good pears, which can be successfully and profitably grown, much shorter. In three orchards of one hundred trees each, on different soils, and with different exposures, and subjected to similar treatment, we find great differences in the thrift and productiveness of the trees. There are not more than ten varieties which will flourish upon our soils. The Glout Morceau is a failure with us, and so are most of the so called "winter varieties." There are but few of these that do not ripen before Christmas under the best conditions for keeping that we can devise. The Bartlett, Duchess, Seckle, Buffum, Louise Bonne de Jersey, and Swan's Orange are the varieties that do best in our orchards. The only early pear really worth cultivating is the Doyenne d'Eté. This is indeed a delicious little pear, and we get a taste of its rich qualities by the middle of August in ordinary seasons. It is rather a vigorous stock, but it needs a moist, retentive soil in which to grow. Osburn's Summer Seedling is only fair, and it is later than the Doyenne.

Among the new varieties of grapes, the Adirondack is worthy of praise. We have fruited it three consecutive seasons, and it is the earliest and the sweetest of all our varieties. It has also proved to be a good bearer, hardy, and the fruit holds well on to the stem. It is a magnificent grape for wine, affording a variety resembling true Malaga. It is so exceedingly saccharine that it needs to be watched closely and handled intelligently, in manipulating for wine. The Israella, of Grant paternity, is also a good and early grape. It closely resembles the Adirondack, but it is inferior in several respects. The Israella is upon the whole a failure. The clusters are beautiful, and the grape a good one; but it ripens late, too late for this locality, and then the ripening is singularly uneven and imperfect. We have bunches which contain berries fully ripe, others partly ripe, and still others as hard and green as the Concords in July. This grape will not do for this section, and we doubt if it proves entirely satisfactory in any locality. The grape and pear crop is abundant this year.

THE ABSORPTIVE POWER OF SOIL.

It is an important discovery of recent date, that soils have the power of separating not only ammonia but other bases also from their solutions, and of holding them with great tenacity after their absorption. Thus 100 grains of clay soil, taken from the plastic clay formation of England, absorbed 1,050 grains of potash from a solution of caustic potash containing one per cent. of the alkali. It is interesting to observe that the liquid was not in this case filtered through the soil, but the cold solution was merely left in contact with it for twelve hours.

It has been further shown that soils have the ability to separate the alkaline bases from the acids with which they are combined. When saline solutions were slowly filtered through soils five or six inches deep, the liquids which passed through were deprived of their alkaline bases, as potash, soda, ammonia, and magnesia, and only the acids were to be found in combination with some other base. Thus when muriate of ammonia was filtered through the soil, the ammonia was removed, and a corresponding quantity of lime, in combination with muriatic acid, was found in the filtered liquid. In the same way sulphate of potash was deprived of its base, and the liquid collected gave sulphate of lime on analysis.

Those soils which have the greatest amount of capillary porosity will condense the greatest amount of manurial substances on their internal surfaces, will retain them longest against the adverse solvent action of water, and will give them out most readily to the rootlets of the growing plant. A mass of adhesive clay will absorb but a very slight amount of available manure; but if this same mass is rendered friable by mechanical processes, its power of absorption is amazingly increased. In view of what has been stated, it is very clear that one way in which ploughing increases the fertility of land is by increasing its porosity by pulverization.

Again, many manurial substances exist in the soil, which, being insoluble, exercise no action on the growth of plants, and contribute nothing to their nutrition; but by the slow, though regular action of the frosts and the rain, the air, and the sunshine, insoluble and refractory compounds are reduced to a soluble state, and are appropriated and held on deposit by the soil to the credit of the next cultivated crop. This explains the well-known fact that soils, which have been cropped to the very verge of barrenness, will recover their fertility if allowed to

remain long enough under the action of climatic influences to saturate the soil with the necessary plant-food which they have unlocked from their chemical combinations, and given to the soil in a proper physical condition. These changes are brought about more rapidly when certain mechanical changes of condition are wrought upon the soil.

Carbonic acid is one of the most active of the agents employed in bringing the insoluble organic matter in the soil into that physical condition in which it becomes available as plant-food; in order that this acid may be formed, it is essential that the carbonaceous matters in the soil should be brought into direct contact with the atmosphere, from which they procure the oxygen necessary to convert them into carbonic acid. So long as stagnant water remains in the soil, or so long as the soil is in a dense or a very compact condition, it is impossible for the carbon to be converted into acid.

FARM-LIFE IN BRAZIL.

A CORRESPONDENT of the *Rural Carolinian* — a most excellent journal, by the way — writes as follows of Farm-life in Brazil: —

" We have lived here in the valley of the Amazon two years and a half, and can therefore speak of the seasons, the soil, the crops, and the people, from actual experience and observation. I shall therefore give facts and not uncertain matters of hearsay.

" We live about six miles by water or seven miles by land from Santarem, which is situated at the mouth of the Tapajos River, there emptying its waters into the Amazon. By reference to the map, you will see that we are nearly under the equator, and yet we are not scorched by the heat of the day, and have cool nights all the year round. This day, June 27th, 1870, at half-past six o'clock, A. M., the thermometer stood at 72° Fahrenheit in my bedroom. We plunged it into a jar of water that stood in the air for drinking purposes, when the mercury fell to 58°; we next immersed it in the stream, about forty feet distant, when the mercury rose to 77°; hence you perceive the stream, in the morning, is much warmer than the atmosphere, and the water in a jar is cooler than the atmosphere. We never feel the want of ice to cool our beverages. We sleep under a blanket or quilt every night the year round. Dews are very heavy here. We have never seen a fog. The water of the Amazon is of a yellowish clay color; that of the Tapajos is clear, and at a little distance looks black; and, for many miles down the Amazon, the two rivers seem to be running side by side, without mingling their waters.

" The nights and days are so near of equal length all the time, that, unless a calculation be made, we would suppose them the same. For example, according to the calculations made for a large scope of the Empire, including the province of Para, December 1st, the sun rises at five o'clock twenty-nine minutes, being the earliest hour that it appears. July 1st, sun rises six o'clock twenty-five minutes, being the latest, and there being only ninety-six minutes difference in the rising of the sun for the entire year; an average of eight minutes per month. September 23d, the sun rises five o'olock fifty-two minutes, and sets at exactly the same hour in the afternoon. March 20th, sun rises six o'clock and seven minutes, and sets the same hour in the afternoon; hence great regularity may be observed by systematic persons.

" The custom in regard to meals is a cup of coffee and a biscuit made of *mandioca* or tapioca at sunrise, breakfast at from ten to eleven o'clock, and dinner at five o'clock.

" But there is a class of people here who have no system, and eat, as they work, irregularly. When the time arrives to prepare a field, they invite their neighbors, who all gather at the house, lounge around, sharpen their *tercados* (a large knife about twenty-five inches or more long), and about ten o'clock the owner tells the men to appoint their officers. When the captain is selected, they all go to the spot, and the captain receives all instructions, and the owner has no more to say. They all set to work and cut down the bushes. During the day they are served with a fermented beverage called *terrabar*, made of *mandioca*. Too much of this will intoxicate, but in moderation it is a nice drink. Tobacco rolled up in the bark of a tree, called *toweree*, is smoked all day long. About four o'clock they quit for dinner, and finish up all the liquor. Thus the field stands until dry enough to burn, when another working party plants it, the men digging the holes, and the women putting in the cuttings of the *mandioca* (pronounced *manioa*). The cuttings are about eight inches in length, and four pieces are stuck in each hill. The work is now done. In nine months from seven to ten hills will give a bushel of roots, if the yield be good. Of these roots they make *farinha*, which is their bread. For the rest, the rivers supply them with fish. But though food is thus easily obtained, they often suffer from want; for as long as they have anything to eat, they will not seek for more. When the last is consumed, and they fail to catch fish, which often happens in certain conditions of the water, they are in want. If you visit them, they are kind and polite, and would give anything they might have, but the trouble is they have nothing.

A small *paliah* house (the *paliah* is a sort of palm), without table or chairs, serves to live in. They sleep in hammocks, eat off of mats on the ground, and use their fingers altogether. They wear but one garment, are generally clean, and bathe often. They regard it no disgrace to be destitute, though an effort would give them abundance. Pine-apples, plantains, and bananas they seldom get, for they will not plant them. It is a good country for stock, yet they do not own a cow or horse, and one dozen eggs could not be purchased at one house. So with everything else. While it is a country of great abundance, you can get nothing. You must buy your supplies in the city, cut down and burn off your land, plant corn, peas, pumpkins, sweet potatoes, okra, tomatoes, pine-apples, bananas, plantains, and many other things, and in three months from planting you have more ready to gather into your storehouse than your entire neighborhood would previously afford.

" The class of inhabitants referred to in the foregoing paragraphs are a mixed race of Indians and their descendants."

THINGS WORTH NOTING.

DOUBLE FLOWER-POTS. — Many plants will thrive better in double pots than in single ones; that is, if the pot containing the plant is placed inside a larger one, with earth between the two. The outer pot prevents the sun from striking with too great force on the inner one, and thus keeps the plant moist, and secures for its roots a more uniform temperature. The suggestion appears to be a good one.

VINEGAR. — The following is an English recipe: Make a syrup of $1\frac{1}{4}$ lbs. of sugar to 1 gallon of water, and to each gallon add a quarter of a pint of yeast. If kept for three days at a temperature between 77° and 86° F. (34° and 38° C.), it will be sufficiently acetified to allow of being drawn off into the ripening cask, where 1 oz. of bruised raisins and 1 oz. of crude tartar are to be added to each gallon of liquor. When the sweet taste has entirely disappeared, it should be drawn off into bottles, and corked down tightly. It is stated that such vinegar will contain as much as 5 per cent. of pure acetic acid. From 2 to 3 per cent. is the average strength.

A HUSK DOOR MAT. — Take an inch board of the size you wish your mat; dress it neat: rule it each way, drawing the lines 1 1–2 inches apart, bore a hole with a 3–4 inch auger in each square; double a piece of broom-twine, pass it through the holes, one at a time; have the husks dampened, take a sufficient quantity to fill the hole very tight, pass it through the loop of twine, draw it through until the double end of the husk is 1 1–2 inches long, draw the twine out, and proceed in the same way until all the holes are filled. Then take a sharp knife, and cut the double husks, spread them apart, trim the uneven side, tramp it down, and set it where it is to be used, either side up.

BEET SUGAR IN ENGLAND AND IRELAND. — The Chancellor of the Exchequer, in his recent speech on the Budget, when introducing the subject of the partial remission of the sugar duties, said: — " We know that the beet-root industry of the Continent seems to have got over its difficulties, and to be spreading very widely. There is also the prospect of the growth of beet-root, with this object, in our own country; and, if we could hope for anything so good as that it should be introduced with success into the south of Ireland, it would be one of the greatest blessings that could possibly befall that country." The sugar-beet has been grown experimentally in various parts of the county of Kilkenny, and the important result has been established that the climate of the south-east of Ireland is suitable for the growth of such a crop, and that sugar-beet can there be grown of a quality which will remunerate the manufacturer. It is calculated that a per centage of 8.5 of crystallizable sugar will pay; and in some instances, comprised within the range of the experiments, there was a yield of 10.91 and of 8.94. That the magnitude of the industry is sufficient to warrant operations on the largest scale is shown by the fact that last year France alone produced no less than 300,000 tons of beet-sugar, which, at £25 per ton, would be worth £7,500,000, the molasses (100,000 tons at £5) bringing up the value to £8,000,000. Beet-root may yet redress the injury inflicted on Ireland by the failure of the potato.

FEATS IN FARMING WEST OF THE MISSISSIPPI. — A correspondent of the *Kansas Farmer* tells the following " tall " story: " I have peach trees grown from seed, planted last spring on upland broken the previous year, which, by actual measurement, are six feet two inches, or seventy-four inches, from the ground up, and over an inch in diameter at the base. How far the roots extend toward China, I never looked to see. I have several that measure over six feet, and hundreds of them over five feet high. I also have apple trees, grown from common nurserymen's root-grafts, set out last spring on the same soil, over five feet in height. I also raised, on the same soil, three and a half bushels of Harrison potatoes, from one potato weighing about half a pound. The ground being measured, the product was at the rate of seven hundred bushels per acre. One barrel ($2\frac{1}{2}$ bushels) of seed gave 300 bushels of potatoes."

A widow in Santa Cruz, California, received over five hundred dollars for the strawberries raised on a half acre of poorly-tended land, this last season. A man in the same neighborhood sold eighty dollars worth of blackberries from less than a hundred plants growing along a fence in his garden. The plants are four years old.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, OCTOBER 1, 1870.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 *Congress Street, Boston, Mass."*

All correspondence relating to editorial affairs should be addressed to the Editor, 150 *Congress Street, Boston.*

A LIBERAL OFFER.

On receipt of the publishers' price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year.

AMERICAN CHEMIST	$5 00
THE ECLECTIC	5.00
EVERY SATURDAY	5.00
THE NATION	5.00
NATURE (*London*)	5.00

THE TECHNOLOGIST	2.00

THE EDITORS AT LAKESIDE.

IT was certainly a rare and interesting sight to look upon the party gathered at Lakeside on the shore of the beautiful Kenoza Lake, Haverhill, Mass., on the 20th inst. It was composed of the Editors of the old Commonwealth of Massachusetts, with their wives, about three hundred in all; and in respect of general culture, intelligence, wit, social accomplishments, and moral worth, it was an assemblage which cannot be surpassed. Probably more than *three millions of readers* were represented by the editors present. It was a private social party of cultivated ladies and gentlemen, full of wit and cordiality, and meeting under circumstances where there could be freedom from ceremony and restraint. We were proud of our guests, and coming as they did from distant homes, from the sands of Cape Cod and the hills of Berkshire, we felt highly honored by their presence. Thus much it is becoming in us to say. As regards the success and enjoyments of the occasion, we prefer that the kind narrations of our guests should be presented rather than any words of our own. The press in this city and in all sections of the State have been pleased to bestow upon it the most generous praise. The *Boston Daily Journal* gave a full report of the proceedings, and from it we take the liberty of making the following extracts: —

"Lake Kenoza, the prettiest sheet of water in Massachusetts, if not in New England, was yesterday the scene of a very happy gathering. Dr. James R. Nichols, the proprietor of the Lakeside Farm, and the editor of the JOURNAL OF CHEMISTRY, sent an invitation last summer to the Massachusetts Editors' and Publishers' Association to visit his residence; but at that time the members of the Association had arranged for a trip to Gloucester, and the invitation of the Doctor had to be set aside. The proposal was again renewed, however, and the 20th of September fixed upon as the date of the visit. More glorious weather certainly never smiled upon any undertaking; more glorious success has never attended any social gathering; all the circumstances conspired to make the day a pleasant one, and one to be long remembered in the annals of State journalism.

"A special train left the Boston and Maine depot in this city at eight o'clock, with the members of the Association and their ladies, for Haverhill. On arriving there, the party at once proceeded to the steamboat wharf, where the barge *Queen of the Merrimack* was in readiness to convey them on an excursion down the river.

"The barge was gayly trimmed with bunting and flags; and as she left the wharf, drawn by the little steam-tug *T. Weed*, the crowd of persons that thronged the wharf, and filled the windows of every manufactory bordering upon the river, waved handkerchiefs and flags, and wished the *voyageurs* a good time. Down the placid Merrimack the barge glided with its cargo of humanity, passing scenes of rare beauty that enchanted the eyes of the beholders, while the strains of the Haverhill Cornet Band held many an ear captive. The picturesque valley was in its full beauty; the autumnal foliage mingled most harmoniously with the greensward, and made a glorious picture in the bright rays of the sun. The barge continued on to the pleasant town of Groveland, just below which she was put about and headed once more for Haverhill, where she deposited her living freight at 11 o'clock.

"On landing from the boat, an informal procession was made, and the entire party, with the exception of the band, walked to the residence of Dr. Nichols, on Summer Street. The house was very tastefully trimmed with the national colors. On entering, the party was welcomed in the most genial manner by their host, who was ably seconded by his estimable lady. Every preparation had been made for the reception of the large number of newspaper men, and nothing that could possibly conduce to their enjoyment had been left undone. Refreshments were served immediately on arrival. The visitors scattered themselves over the lower portion of the house, enjoying the collection of the articles of art and *vertu* which were to be found in nearly every room. Many lingered before the large and excellent painting of Lake Kenoza, one of the latest productions of Mr. Thomas Hill, the well-known landscape painter, who has done full justice to the beautiful spot. At last the carriages were announced, and the party was soon on the high road to Lake Kenoza, which fully sustains the reputation it has so long enjoyed, and bears out the words of Whittier, that —

'O'er no sweeter lake
Shall morning break or noon-cloud sail.'

"The drought has not apparently affected to any considerable extent the spot where the Quaker poet laid the scene of 'Snow Bound,' and where he passed his early life, for everything looked fresh and beautiful yesterday. The five miles of land skirting the clear water were soon dotted with visitors, who climbed to the summits of little hills, and eagerly drank in the beauties of the place. The boats stationed at the wharf were at once engaged in taking parties out for a sail. Then the Quintette Club and the Haverhill Cornet Band were stationed in front of the Doctor's splendidly decorated house, and performed at intervals, together with a quartette choir, composed of Mrs. J. E. Houston West, Mrs. C. A. Barry, Mr. M. W. Whitney, and Mrs. F. C. Packard, whose efforts always met with applause. So the time was spent until one o'clock, when the dinner was served in a large decorated tent on the lawn. The tables presented a truly magnificent sight, loaded down, as they were, with fruit of all kinds. The meal was a first-rate one, in thorough keeping with the well-known hospitality of the host, and the place in which it was given.

"At the conclusion of the meal, the chairman, Dr. Nichols, called the company to order, and delivered the following address of welcome: —

'I have the very pleasant duty to perform of welcoming to our young city, and to this rural retreat, the Editors and Publishers of the old Commonwealth of Massachusetts. I feel highly honored in having for my guests so large and so distinguished a company, gathered from so many and distant homes. I ventured to invite my brother editors to this place, feeling that a humble hospitality, a social, free, and easy reunion, would not be distasteful or altogether unacceptable. I believe in large families; and having in former seasons gathered around these tables the farmers, the doctors, and the clergymen of Essex county, there was still room left for more. The space which my friends in the county could not fill I felt might possibly be closed up by drawing upon the whole Commonwealth. But it would be impossible to fill these voids satisfactorily without the ladies, and we have the great pleasure of greeting the ladies at our table, and now the measure of our satisfaction ought to be complete. We have to regret the absence to-day of one who in early life was inspired by the rural scenes around us, — by these woods and hills and these quiet waters, — so that his poems are read with delight wherever the English language is spoken. Mr. Whittier hoped to be with us to-day, and I am sure we should all of us have been glad to take him by the hand. In a letter received on Saturday, he expresses a strong desire to visit these old haunts of his childhood, and join our festivities, but illness prevents. If we cannot greet the poet to-day, we can read a few of his charming lines, which have a local interest. The lake and the shore on which we are assembled Mr. Whittier has commemorated in verse: —

'The shores we trod as barefoot boys,
The nutted woods we wandered through,
To friendship, love, and social joys
We consecrate anew.

Here shall the tender song be sung,
And Memory's dirges soft and low,
And wit shall sparkle on the tongue,
And mirth shall overflow,

Harmless as summer lightning plays
From a low, hidden cloud by night —
A light to set the hills ablaze,
But not a bolt to smite.

Kenoza! O'er no sweeter lake
Shall morning break, or noon-cloud sail;
No fairer face than thine shall take
The sunset's golden veil!

And, Beauty's priestess, thou shalt teach
The truth so dimly understood,
That He who made thee fair for each
And all designeth good.'

"The President of the Association, Mr. Stockwell, was then called upon by Dr. Nichols, and he made a brief address, in which he said that his brethren of the press, in fixing upon his name for President, had forgotten one thing, or else they did not know of it at the time, that they had selected a man who

could not make a speech. Looking upon that scene of beauty before them, which he believed was unparalleled by anything he had ever seen, he thought if a man was at all able to make a speech it should be at that time and place. He simply rose to express, on behalf of the Association, his most hearty thanks to the honored host for his very kind and liberal entertainment. He closed by proposing the health of their generous and respected host, Dr. Nichols.

"The chairman explained that several persons had been invited to be present, but were unable on account of sickness, among them being Governor Claflin and John G. Whittier. In the absence of the Governor he called upon Judge Russell, who responded as follows: —

'My friends, it would be the greatest honor of my life, if, for five minutes, I could worthily represent William Claflin. I thank you, Dr. Nichols, for all that I have enjoyed to-day; for the beautiful sights that we have seen, and the sweet voices that we have heard — for everything — except this call. As we looked upon the unsurpassed valley of the Merrimack, the sleeping river, the groves on either side, the rounded hills, the thriving city — model of a New England town — and now upon the blue waters of the lake, the whole landscape tinged by the haze of Whittier's poetry — all bathed in sunlight and in this pure air; bathed, also, in the light and atmosphere of a generous hospitality, — the words of the familiar hymn occurred to me:

If God hath made this world so fair,
Where sin and death abound,
How beautiful beyond compare
Will Paradise be found!

'But, at once, I recollected the words of a hymn equally familiar: —

Each pleasure hath its danger, too,
And every sweet, a snare.

'The danger which alloys this pleasure, the snare which attends these sweets, is the peril of having to make a speech. Wonderful is the county of Essex. Yesterday, some of you stood at Cape Ann, and saw a new development of the energy and enterprise which turns our New England granite into gold, the same energy and enterprise, which, at the call of loyalty, headed the march and saved the Capital. To-day we have heard and seen something of the skill which applies science to agriculture; which gives us delicious fruit, not the product of the earth, but of the crucible, and which is destined to feed millions, and to renovate the surface of the civilized globe. I hardly trust myself to speak of the wonders to be wrought by agricultural chemistry. It will build up the waste places of our own State, those little towns dear to their sons, of whose decline we read in the census with grief and fear for the future. Their worn-out soil shall be renewed; their decay shall be checked; once more they shall be thriving members of a great commonwealth. The men who teach this wisdom are benefactors of the race. We used to think of chemistry as a harsh and crabbed study. Its emblem was a wrinkled old man, bent down over a blowpipe, with a smoky crucible and a discolored retort. Now chemistry is a good fairy, making all things fresh and new, scattering from her open hands the golden grain, the purple grape, the rosy fruit.

Flowers laugh before her on their beds,
And fragrance in her footing treads.

'And a mightier power is represented here — without crucibles (not always without retorts) — the Press. This, also, keeps the earth fresh, and builds up waste places. When the sounds of war are hushed, this power shall make the Old World young again. Happy day, when the representatives of these great powers meet. Twice happy when they meet on the shores of Kenoza Lake.'

"Other speeches were made by Rev. Dr. Seelye, and Mayor Whittier, of Haverhill; Mr. C. F. Guild, of the *Commercial Bulletin*; Major Ben. Perley Poore; Hon. C. W. Slack, of the *Commonwealth*; Mr. G. W. Bull, of the Buffalo *Commercial Advertiser*; Rev. Asa Bullard, of the *Well-Spring*; Hon. Simon Brown, of the *Farmer*; and by Mr. Robbins, of Waltham; all of which were of a congratulatory and pleasant character. A poem was also read by Mr. G. A. Marden, of the *Lowell Courier*, which abounded in good and spicy hits and humor, and was most warmly received by the audience.

"At half past four o'clock the entire party left the grounds in carriages, and proceeded to the Haverhill depot. The train left at five o'clock, and arrived in this city an hour later, bearing on it a crowd of people who had spent a pleasant day."

COMPLIMENTARY.

THE *Boston Transcript* contains the following remarks regarding the article upon the Chemistry of the Human Body, published in our August number. For the very kind and complimentary allusions to the JOURNAL, we are under great obligations. We are constantly receiving from the press, in all sections, the most warm and generous commendations, for which we are grateful. As intimated by the editor of the *Transcript*, the name of our journal hinders large numbers from becoming acquainted with it, who, if they understood its character, would be among its warmest supporters. A journal of *chemistry*, many think, must be a dry and uninteresting publication, and therefore they never examine it. Our friends who *do know* what the JOURNAL *is* must help us in disseminating information regarding it. All we need is to be *known* and *understood*, and our friends will be numbered by tens of thousands.

"OUR MAKE UP. — Science has no respect for romance. Physiology is regardless of sentiment. Physical facts are not poetical. The moment you talk of the human body, as does the BOSTON JOURNAL OF CHEMISTRY, away goes the ideal, the fanciful, the imaginative, and down you come to statements that are of the earth, earthy. These statements are, nevertheless, interesting and instructive, and the analysis they report will amuse and inform many who are ignorant of their corporeal composition. The JOURNAL takes to pieces an adult weighing one hundred and fifty pounds, and approximately gives his elements, to the number of fourteen — as we count. Chiefly the subject is oxygen and hydrogen combining in the form of water, of which compound he possesses about 110 lbs., or fourteen gallons; enough to drown him, if it were contained in a suitable vessel; and "water" — the savant grows rhetorical — "flows through our life, as it flows through mountain cataracts and meadow springs, unchanged and unchangeable," as to its own identity. Then the JOURNAL puts other matters attractively in this illustrative style: —

"'Of phosphorus, every adult person carries enough ($1\frac{3}{4}$ pounds) about with him in his body to make at least 4,000 of the ordinary two-cent packages of friction matches, but he does not have quite sulphur enough to complete that quantity of the little incendiary combustibles. This phosphorus exists in the bones and in the brain, and is one of the most important constituents in the body. Every schoolboy is acquainted with those strange metals, sodium and potassium, for he has seen them flash into a brilliant flame when thrown upon water. The body contains $2\frac{1}{4}$ ounces of the former, and a half-ounce of the latter metal; enough for all needed experimental purposes in the schools of a large city. The twelve grains of magnesium wou[ld] be ample in quantity to form the "silver rain" f[or] a dozen rockets, or enough to create a light whi[ch] under favorable conditions could be seen for a di[s]tance of twenty miles.'

"These are only specimens of an amusing artic[le] which shows how plain and clear may be made common folks what common folks will be the wis[er] and healthier for knowing. This paper exemplifi[es] the character of the periodical in which it appears a periodical that deserves special commendation general readers, for it is admirably conducte[d]. Whilst studying to be accurate and up to the lates[t] discoveries, it is free from guess-work and untrie[d] theories, and aims to talk about wonders and th[e] most subtle investigations, in language that everybod[y] can understand. Its title should not deceive any body into the erroneous supposition that it is of us[e] only in the laboratory, school, or lecture-room, an[d] out of place in the company of newspapers an[d] magazines for home consumption."

A SIGNIFICANT FACT.

NOTWITHSTANDING that a million of soldie[rs] belonging to the French and Prussian armie[s] have been trampling down and laying waste th[e] magnificent vineyards in the great champagn[e] district around Rheims, Epernay, etc., the pric[e] of the wine has not been affected in the leas[t] in this country. So extensive and destructiv[e] have been the military operations in the depart[]ment of which Rheims is the most importa[nt] city, that the vintage this year is almost a tota[l] loss, and the wine factors have to a great exten[t] had their stocks of wines destroyed. Any on[e] would suppose this would produce a pani[c] among dealers and consumers of the effervescin[g] wines, but such is not the case. The truth is in the manufacture of the beverages now sold as wine, the juice of the grape is of no account. A large part of that which is sold in this countr[y] is made from cheaper and more gross materials and we suppose if the vintage should utterl[y] fail abroad for twenty consecutive years, th[e] supply of *wine* would not in the least diminish Some time ago, when the terrible *oïdium* des[]troyed the vine in Madeira for several years and not a cask of wine was made upon th[e] island, the supply of *genuine* Madeira was neve[r] greater or the price cheaper. Wine-drinker[s] may take encouragement from these facts.

THE NEW FURNACE. — It must be distinctly understood that we cannot assume any responsi[]bility regarding furnaces made by any partie[s] anywhere, who claim that they are constructe[d] after our device. Our duty was discharged, an[d] our ends reached, in fully describing new improvements for rendering furnaces more health[]ful and comfortable. Manufacturers must be held fully accountable for any *imperfect, leaky* apparatus which they may construct after our model, and purchasers must protect themselves in this matter. The improvements we have suggested are *very important*, and we have described them for the benefit of housekeepers. If the apparatus is *carefully and perfectly* constructed, it will afford great comfort and satisfaction; if it is not, it will be worthless.

Messrs. Lebosquet Bros., of Haverhill, Mass., who advertise the furnace in the JOURNAL, are responsible gentlemen, and we think have taken great pains to construct it properly. We have

no time or inclination, however, to look after or examine any one's work, and those who construct must be held accountable for the perfection of their mechanical labors.

EDITORIAL NOTES.

Organic Matter in Water. — New facts on this interesting subject are continually coming to light. Dr. Heinsch, in a paper communicated to the London Chemical Society, states that not long ago he was called on to assist a large manufacturer of lemonade, who suddenly found it impossible to make lemonade that would keep. After a day or two it became turbid, and its odor anything but agreeable. On investigating the liquid under the microscope, it was found full of small spherical cells with, in most cases, a very bright nucleus. After examining all the materials employed, it was decided that the fault was with the water. On putting a few grains of pure crystallized sugar into some of the water, it became turbid in a few hours, and contained the cells above mentioned. On inquiry it turned out that the well, from which the water for the preparation of lemonade was obtained, had been slightly contaminated by sewage. This led the experimenter to mix a minute quantity of sewage with a sugar solution; the cells very soon made their appearance. Filtration through the finest Swedish paper does not remove the germs. Boiling for a half hour in no way destroys their vitality. Filtration through a good bed of animal charcoal seems to be the only effectual mode of removing them; but it is necessary to air the charcoal from time to time, else it loses its purifying power.

New Form of Spectroscope. — The Bowdoin Scientific Review describes a simple device hit upon in the laboratory at Brunswick, specially adapted to blow-pipe determinations: "If the lenses be removed from an ordinary spectacle frame, and one of them be replaced by a very small direct-vision spectroscope, we have the instrument in question. The direct-vision spectroscope may consist of the following parts: a compound prism consisting of one flint and two crown-glass prisms, suitably united, and an achromatic lens, all properly mounted in a small tube having an adjustable slit exactly in the focus of the achromatic lens. This instrument may be worn like ordinary spectacles; thus releasing the hands of the operator for necessary manipulations. By this device we are enabled with one eye to study the spectrum while with the other we direct the operations necessary to its production.

☞ Prof. Edward S. Morse, whose scientific researches have during the past two or three years excited great interest in the scientific world, is one of the most attractive and instructive lecturers upon science, before popular audiences, that we have ever known. His lectures upon "How Animals Move," "How Animals Eat," etc., will delight any lyceum audience in the country. His blackboard illustrations cannot be surpassed. We do a service to the community, in recommending Prof. Morse to the attention of lyceum committees. He can be reached by addressing him at the Peabody Academy, Salem, or at the rooms of the Natural History Society, Boston.

☞ With this month's paper we send reminders to the few subscribers who have not already paid for Vol. V. As these bills have to be prepared in advance of the mail, it is possible that some may be sent to those whose money was received too late to be credited in this month's issue. If this happens, we beg the indulgence of our friends. Persons sending drafts or checks will please make them payable to the order of Geo. S. Chase.

In this connection we would call special attention to our club list of magazines and journals on page 43. Those who wish to subscribe for any of these periodicals can obtain the renewal of the Journal *gratis* by sending their subscriptions through us.

☞ The notice of the offer of the Lamb Knitting Machine, as a premium for sixty subscribers, is unavoidably crowded out of our advertising columns this month; but our friends will understand that, as already announced, the offer holds good *until November 1st.*

LITERARY NOTES.

The *Annual Record of Homœopathic Literature* for 1870, edited by Dr. C. G. Raue, has been issued by Messrs. Boericke and Tafel, of New York. It is a handsome volume of more than four hundred pages, exclusive of some eighty pages of "Statistics" added by the publishers; forty-four of these being filled with the names of homœopathic physicians in the United States.

The American reprint of the *Chemical News* has been given up, and in its place we have *The American Chemist*, which looks very much like it, but on examination will be found to be largely made up of original articles that will compare not unfavorably with those in its English prototype. The new monthly is edited by Prof. C. F. Chandler and W. H. Chandler, A. M., and is published by Messrs. W. Baldwin & Co., of New York. By an arrangement with them, we are able to furnish it with the Journal at *five dollars* a year, which is the regular price of the *Chemist* alone.

Scientific Opinion, noticed in our July number, has been merged in *The British Mechanic and Mirror of Science*, a weekly paper published by E. J. Kibblewhite, 31 Tavistock St., Covent Garden, London. This journal, which for *twopence* (four cents of our money) gives twenty-four closely printed quarto pages of excellent reading, illustrated with good wood cuts, appears to be very successful, having recently absorbed not only *Scientific Opinion*, but the *British and Foreign Mechanic* and another *Mechanic*. It is a very Aaron's rod among contemporary English journals of popular science.

The Appletons have issued their *Annual Cyclopædia* for 1869, of which it is enough to say that it is fully up to the standard of the eight yearly volumes that preceded it. Encyclopædias in general begin to be out of date as soon as they are completed; but by this annual supplement, published in style uniform with the original work, the *New American Cyclopœdia* renews its youth every twelvemonth, and thus keeps constantly "up with the times."

Messrs. Wilson, Hinkle, & Co., of Cincinnati, have sent us *The Elements of Astronomy*, by S. H. Peabody, A. M., of the Chicago High School. It seems to us one of the best of the half dozen textbooks of Astronomy published within the past year or two. It is intended to be a part of "Ray's Mathematical Series," which is so extensively used at the West.

The first number of a semi-monthly journal of medical and surgical science, called *The Medical Times*, is announced for October 1st, by Messrs. Lippincott & Co., of Philadelphia. The price is to be $4.00 a year, and we will furnish it *with the* Journal on receipt of that amount. The name of the publishers is a guarantee that it will take a high rank among its professional contemporaries.

In reply to several inquiries, we would say that the article on "The Microscope in Medicine," in our August number, was an extract from *Clinical Lectures on the Principles and Practice of Medicine*, by Prof. John Hughes Bennett, of Edinburgh. The fifth American edition of this standard work, from the fourth London edition, was lately published by Messrs. W. Wood & Co., of New York.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home, science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

T. B. M., Chester, N. J. — There are countless recipes for cologne-water. One that will furnish "a good article at a moderate price" is the following: oil of bergamot, lavender, and lemon, each one drachm; oil of rose and jasmine, each ten drops; essence of ambergris, ten drops; alcohol, one pint. Mix and keep well stoppered in a cool place for two months, when it will be ready for use.

F. R., Washington, D. C. — There *is* ordinarily "air diffused through water." If your friend who disputes the fact were a fish, he would find that he could breathe well enough in water in its natural condition, but would soon die of suffocation in water from which the air had been removed by an air-pump.

L. B. S., Boston, asks whether any of our correspondents can give the exact locality, or addresses, of the grape-sugar manufactories mentioned in our September number.

He also makes the following suggestion: "For apothecaries' labels, why not transcribe the recipe and place it on the package, keeping the original, numbered and on file?"

Our friend appears to doubt some of the stories of adulteration given by us. We can assure him that they all come from the best authorities.

J. S., Mobile, Ala. — Phalon's "Vitalia" *is* one of the "hair restoratives" that contain lead, as may be seen by Prof. Chandler's Report, referred to in our July number. It has 4.69 grains of lead to the fluid ounce, whether the statement of the advertisements that it is "without sediment" be true or not.

Violet Ink. — Several correspondents have asked for a recipe for violet or "mauve" ink. We cut one from the *Druggist's Circular* some time ago, but have mislaid it. These inks, however, are not to be recommended, as they are all more or less liable to fade.

Medicine.

BEHIND THE BARS.

A series of very remarkable papers, with this caption, have appeared in the *Boston Courier* during the year past, and they are not yet completed. These papers discuss the subject of our asylums for the insane, and the plans or systems adopted in treating those unfortunate beings who are placed "behind the bars." The writer is evidently a highly cultivated, discriminating, and candid man or woman, who has had experience as patient in one of our first-class Massachusetts asylums; and the descriptions given of the treatment are evidently founded upon personal observation and experience. We must confess to a feeling of perplexity and astonishment as we read these disclosures. They are clearly not the vagaries of an unsound mind, they do not spring from wounded pride or from resentment, they are not sensational, but they are calm, clear, fair, explicit.

The writer describes the day and night routine of the asylum, the system and duties of nurses and assistants, and the intercourse of the attending physicians with the patients; and if what is presented is true, it is evidently some one's duty to inquire into the treatment pursued in these institutions. No charges of gross cruelty or intentional neglect are made, and we fail to observe any desire to cast blame upon individuals; but the revelations in regard to the *system* are startling. We are all of us, at any moment, liable, through disease or morbid mental disturbance, to be precipitated into a condition where our friends will regard it as an act of mercy and kindness to place us "behind the bars." We all have an interest, a very deep interest, in the conduct of our asylums for the insane; but physicians more than others should most fully and clearly understand the exact situation in which they place their patients when they direct their removal to these asylums. We have never yet, in our experience with the

world, found anything so perfect that it did not have faults; and we have certainly learned that what we regarded as most perfect and desirable was just what needed to be thoroughly reformed or changed. It may be that our asylums, which appear when we visit them so cleanly, so orderly, so cheerful, are, after all, conducted on a wrong plan, or that the *system* is very defective. The gentlemen who have them in charge are good men, kind men, skillful men; but all this does not prevent them from falling into a routine so detrimental to the interests of the sick and suffering ones in their charge, that important changes may be needed. In stating that the physicians who have control of the asylums in Massachusetts are good and skillful men, we state what is true. Several of them are our warm personal friends, and we know they are incapable of doing any act of unkindness to a patient or of knowingly allowing such on the part of assistants. Assuming, then, that the statements of the writer of the articles in question are faithful records of facts, how do we explain the apparent inconsistencies of the position? Simply by reference to the *system* of hospital treatment for the insane, which it is quite easy to believe is objectionable in several important particulars. Massing together in one large building two, three, or five hundred human beings suffering from various forms of mental hallucination, and subjecting them to the routine treatment of a hospital, may not be, nay, cannot be, the best plan of treatment. More than one half of those who are placed in asylums are sufferers merely from nervous derangements which rest and quiet, with sound sleep, will cure. Such ought not to be placed in the same building with those who are confirmed maniacs, or those who are demented. As the nature and treatment of mental derangements are better understood, we are confident that a system of quiet retreats situated in the country, each having but few patients, and these carefully classified, will be found to be much the best. But we have not time or space properly to discuss this most important question. It is the intention, we believe, to publish the *Courier* articles in book form, as soon as the series is completed; and then, having the whole matter before us, we shall refer to it in a more extended manner.

Cincho-Quinine. — The San Francisco apothecary and medicine manufacturer, Mr. W. T. Wenzel, must be highly delighted with his experiment in obtaining gratuitous advertising, as we notice that nearly all the so-called "pharmaceutical" journals have copied his "paper" upon Cincho-Quinine, in whole or in part. Hereafter, if any enterprising druggist wishes to rise to the dignity of a "chemist," let him sit down, and, with the aid of the U. S. Dispensatory and some elementary work upon chemistry, "construct" an "analysis" of some medical compound, no matter what, and send the results to the nearest "pharmaceutical" publication. Like the advertisement of the old physician whose "sands of life have almost run out," it will "go the rounds," provided it is sufficiently sensational. We have once remarked in the Journal that the statements of Mr. Wenzel respecting cincho-quinine were unreliable and absurd. The compound, as prepared by Messrs. J. R. Nichols & Co., contains all the alkaloidal principles of bark, and is constituted precisely as described in an article published in this Journal. It is a very important remedial agent, and one which is fully appreciated by thousands of physicians in all sections of the country.

OUR MEDICAL EXCHANGES.

The American Practitioner for September has original articles on the Safety of Chloroform in Labor, by Professor L. P. Yandell; on a case of Tetanus treated with Calabar Bean and Hydrate of Chloral, by Dr. Preston Peter; on a similar case treated with Calabar Bean, by Dr. Edward Richardson; and on the cause of Malarial Fevers, by Dr. Duff Child; with Reviews, Clinic of the Month, Notes and Queries, etc.

The New York Medical Journal has a paper of twenty-eight pages on Intra-Uterine Medication, by Dr. F. D. Lente, and a continuation of one on the Internal and External Use of Mineral Waters by Dr. Adolph Kessler; with much valuable matter under the heads of "Clinical Records from Private Practice," and "Reports of the Progress of Medicine."

In the *Chicago Medical Journal* the leading articles are on Uterine Fibroid of the Posterior Wall successfully Removed, by Dr. A. Reeves Jackson; a Statistical Report of Diseases of the Ear, by Dr. E. L. Holmes; and on Hydrate of Chloral, by Dr. J. C. Bascom. The translation of Prevost's "Experimental Investigations relative to the Directions of Rotary Movements due to Unilateral Encephalic Lessons" is continued.

In the *Baltimore Medical Journal* we note, among other original matter, interesting papers on the Diffusion of Disease, by Dr. T. S. Latimer, and on the Anatomical and Physiological Differences between the Caucasian and African Races, by Professor H. L. Byrd.

The Indiana Journal of Medicine is publishing by installments an elaborate paper by Dr. R. E. Haughton, on the Repair of Wounds by Granulation. The editorial articles on Medico-legal Investigations and on the Hygiene of the Farmhouse are likewise noteworthy.

The Journal of the Gynœcological Society of Boston (we wish it could abridge its name!) is, as usual, excellent in its way. We understand that this magazine will be considerably enlarged next year.

The leading article in the *Boston Medical and Surgical Journal* for several weeks has been an able discussion of "Aphasia and the Physiology of Speech," by Dr. T. W. Fisher. Dr. W. W. Wellington's discourse on "Modern Medicine," delivered before the Massachusetts Medical Society at their last annual meeting, is reviewed at length, and highly commended, in the number for September 15th.

MEDICAL MEMORANDA.

Dickens and the Doctors. — In an article on the death of Charles Dickens, the *British Medical Journal* remarks: —

"How true to Nature, even to their most trivial details, almost every character and every incident in the works of the great novelist whose dust has just been laid to rest, really were, is best known to those whose tastes or whose duties led them to frequent the paths of life from which Dickens delighted to draw. But none, except medical men, can judge of the rare fidelity with which he followed the great Mother through the devious paths of disease and death. In reading "Oliver Twist" and "Dombey and Son," or "The Chimes," or even "No Thoroughfare," the physician often felt tempted to say, "What a gain it would have been to physic if one so keen to observe and so facile to describe had devoted his powers to the medical art." It must not be forgotten that his description of hectic (in "Oliver Twist") has found its way into more than one standard work in both medicine and surgery (Miller's "Principles of Surgery," second edition, p. 46; also, Dr. Aitken's "Practice of Medicine," third edition, vol. i. p. 111; also several American and French books); that he anticipated the clinical researches of M. Dax, Broca, and Hughlings Jackson, on the connection of right hemiplegia with aphasia (*vide* "Dombey and Son," for the last illness of Mrs. Skewton); and that his descriptions of epilepsy in Walter Wilding, and of moral and mental insanity in characters too numerous to mention, show the hand of a master."

To make Hydrate of Chloral Palatable. — The following combination serves to intensify the action of the chloral, and covers the acrid taste: —

Hydrate of chloral, . . .	ʒss.
Chloroform water, . . .	ʒij.
Syrup orange, or tolu, . .	ʒiij.
Tincture of ginger, . . .	6 to 12 drops.
Water, ...	℥jss.

The chloroform water is prepared by dissolving half a fluid ounce of chloroform in one gallon of water.

Hydrate of Chloral. — The advantages of chloral over all other hypnotics are concisely stated in the *Lancet* thus: —

1. It is more uniformly certain in its action. 2. It has no depressing influence. 3. It does not cause constipation. 4. It does not produce nausea. 5. Its effects are more lasting.

It is the most valuable means of producing sleep known to physicians. The only difficulty is to fix the exact dose for each case; but this is obviated by beginning with half-drachm doses, and increasing them by ten grains until the limit is found.

A Harmless Hair Dye. — The *Cincinnati Medical Repertory* states that a substance for a safe and effective hair dye can be found in the black walnut. This can be obtained by macerating the green hulls in water; the coloring principle is taken up, and this is imparted to the hair by application; but it should be applied carefully, as it will stain the skin also.

After the hair is thus colored, the following mixture applied for a few nights will improve its appearance much more than any of the ordinary hair oils. Mix equal parts of water and glycerine, and to each pint of the mixture add lac sulphur ʒij, and a few drops of oil of bergamot. Before this compound is applied, it should have a severe shaking, so as to mix the sulphur with the fluid. Apply once or twice a week at night.

The Bullet-cure for Ileus. — The old remedy for colic, of a bullet taken into the stomach, has been revived, in a modified form, by Dr. Maydieu, of Argent, France. In the *Journal de Med. Pratique*, Dr. M. declares that, after seventeen years of the ordinary treatment, in which he always failed, he has been invariably successful in the twelve cases which he has treated with *shot*. He mixes No. 5 shot, after careful washing, with olive-oil sufficient to cover them, and gives a dessert-spoonful every half-hour. In five or six hours the vomiting ceases, gases are expelled, and the bowels are moved. Warm baths, fomentations, and injections of milk and honey, are always superadded.

Apropos of this treatment, the *Pacific Medical and Surgical Journal* tells the following anecdote. Some forty years ago, a travelling preacher in England was taken sick with colic, in the house of a kind old lady, where he was spending the night. The good lady brought a bullet, which, after warming, she induced him to swallow. He was soon relieved from pain, and then began to reflect on the course of the bullet, and at last suggested to his nurse a doubt whether a body so heavy could find its way through the intestinal labyrinth, fearing that it would lodge there permanently. "You need not be the least

said," said the lady, cheeringly, "for that very bullet has gone through *me* at least twenty times!"

MEDICAL AGRICULTURE. — At a recent meeting of the Paris Surgical Society, M. Marc Sée related a case of what he termed "epidermic grafting." The patient had his arm caught in some machinery, the soft parts of the anterior and external portions of the fore-arm and of the elbow being lacerated and crushed, the bones not sustaining any injury. The wound was dressed with pure alcohol, and its surface, after the elimination of the superficial portion which became gangrenous, was covered with granulations. M. Sée then took two small shreds of epidermis detached from the inner side of the arm by means of a lancet, and applied them to a prominent part of the wound. Some days afterwards a new graft was formed by depositing on the surface of the wound epidermic particles obtained by scraping the cutaneous surface of the arm with a lancet. The same day, M. Reverdin, an *interne*, who is the inventor of this form of grafting, applied to the wound several small epidermic shreds taken from the leg and kept *in situ* by a strip of diachylon. In a day or two these different grafts had taken hold, and soon after the epidermic islets extended and united, so as to produce cicatrization over a notable portion of the wound. The process of proliferation of epiderm cells replaces that of suppuration at the points invaded by the islets so that the process of healing is considerably expedited.

CELESTIAL PHARMACY IN NEW YORK. — Ling Wu, a Chinese charlatan, has taken up his abode in Gotham, where he advertises his imported materia medica of 300 "remarkable medicines," with imported apothecaries to dispense them. Referring to this addition to the medicinal advantages of the metropolis, the *Medical Gazette* states that the San Francisco custom-house authorities recently seized an invoice of "remarkable Chinese remedies," consisting of pickled monkeys, dried toads, and such like articles. An elegant Mongolian prescription might read: —

℞. Pulv. unguis pollicis pedis . . grs. v.
Bufonis exsiccati rasi . . . ʒ j.
Caudæ soricis ustæ, q. s. ad. gratum saporum.

Tritura bene, et in chartulis v. divide, quarum capiat æger unam bis in die.

THE EFFECT OF HEAT ON ORGANIC GERMS.

FROM the last of a valuable series of articles on "Microscopic Organisms in Milk," contributed to *Scientific Opinion* by Mr. C. S. Wake, we extract the following curious facts concerning the effect of heat upon organic germs: —

"The effect on organic germs of exposure to great heat is still unascertained, and I determined to try the effect of continued boiling on milk. For this purpose I kept a small quantity of the liquid, in a covered saucepan, on the fire for ten minutes after the first ebullition; but, as I might have expected, the milk at the end of that time was completely desiccated, and there remained only the burnt remnants strongly attached to the bottom of the saucepan. Not to be beaten, however, I scraped off some of this residue and placed it in a bottle about half full of distilled water. On examining this infusion in a week's time, I was surprised to find that it contained animal life in great abundance. Each particle of burnt substance was surrounded by a mass of organic matter, and had attached to it great numbers of small infusoria, which endeavored, by continual jerking movements, to free themselves. I let this infusion stand for about three weeks longer, and the phenomena it then presented were extremely curious. From many of the masses of burnt matter long filaments had grown, and to these were attached numerous spores or germs, connected by very fine fibres with a few larger round bodies, resembling somewhat the original milk globules, but, still more, encysted infusoria. Occasionally, moreover, there were small fungoid stems, evidently due to the union of several oval bodies, and probably forms of the ordinary milk fungus. Among the black burnt particles were several pieces of a lighter color, which I thought might perhaps be foreign matter. On examining this, however, it was found to present exactly the same phenomena, the whole mass of matter consisting, apparently, of a fine fibrous substance, containing numerous large and small spherical bodies, and having many infusoria attached to it. The filaments were more abundant, and the minuter forms of infusorial life were also more plentiful than in the case of the darker particles of matter. My attention was, however, chiefly attracted by several strange-looking bodies, of irregular form, which I could not understand. On altering the position of the lens, a greater number of them became visible, and I then found that they were unmistakably amæbal organisms. I never saw so many of these creatures together before, there being dozens of them within the field of the microscope at one time. They were all of analogous character, and not unlike small forms of *amœba princeps*, presenting the club-like protrusions of this organism. The alterations of shape which they underwent often succeeded each other very rapidly. That these amæbæ had come from the mass of burnt matter was evident. They were, as a rule, almost close to it, and might have been squeezed out of it by the pressure of the glass covering placed on the slip. On examining another mass of matter which had been more perfectly desiccated than that just described, several of these organisms were visible in a cleft which divided two portions of the mass. From a third piece of this substance the amæbæ appeared to be issuing while in the field of the microscope. In fact, such an origin for them will alone account for their marvelous abundance. But what explanation can be given of their presence in such a peculiar position? The only suggestion I can offer is that the spherical bodies, of which a great portion of the burnt matter appeared to be composed, were in reality amæbæ *sarcoblasts;* with the figures of which, given by Dr. Wallich, they well agree. This, of course, only half meets the difficulty. The presence of the sarcoblasts in desiccated milk requires also to be accounted for, and this is a question the solution of which it may be as well for me not to attempt. I may mention that I preserved the slip which showed such an extraordinary number of amæbæ, fastening down the glass cover with asphalte, and on examining it under the microscope I now find that the amæbæ have taken an encysted form; at least, I can find nothing but a number of circular bodies to which to refer them. It should be added, that some of the larger round bodies attached in clusters to the fungoid filaments bore a dark *green* tint, which gives them a very characteristic appearance, and I could fancy that some of the larger infusoria present in the infusion also have this tint. Most of the infusoria are of the same character, a form which I do not recognize as having met with elsewhere. When in a particular position, they have much the shape of *Kolpoda cucullus*, but they are very slow in their movements; and if they turn over, as is often the case, they are then seen to be very broad, and their resemblance to cucullus is lost. It may be as well to state that large bodies, like starch cells, are occasionally to be met with in this infusion, but whence derived I cannot say. These bodies, however, are peculiarly plentiful in an *almond* infusion; with which I am experimenting, and in which, as I expected from the general similarity in appearance, under the microscope, of milk of almond and that of the cow, I have already met with the ordinary milk fungus and the ovate cells with which it is associated."

FALSE PRETENSES OF QUACKS.

ONE of the dodges of nostrum venders, and a very successful one, too, is the adoption of the title "Reverend." *Rev.* Mr. —— has a recipe which has cured him of consumption, and out of motives of pure benevolence he will furnish it free of cost to any one who will send for it, and inclose a postage-stamp to pay return postage. The recipe comes, but it contains an ingredient or two that you search for in vain at your druggist's, under cover of names which cannot be found in any medical or botanical work; but our benevolent "Rev." has a supply (and a pretty large one it must be!) which he brought with him from foreign parts, and he will furnish the medicine already prepared for — only two dollars! This class of impostors have no "local habitation." Their letters are addressed to a certain street and number, but they can never be found at home. They operate through the mails alone.

Another of the class accompanies the advertisement of his nostrum in newspaper and railway car with what purports to be his "counterfeit presentment," with black coat, white choker, flowing hair, and preacher-looking countenance.

The *old nurse* dodge is another. A druggist concocts a lethean mixture, calls it "Nurse Thompson's Soothing Syrup," and anon all good nurses and careful mothers, who think that if their babies "sleep" they "do well," supply themselves with, and keep constantly on hand, the dangerous opiate compounds, which too often give their innocent babes the "sleep that knows no waking." The slaughter of the innocents by these soothing mixtures is fearful, and we have no doubt that much of the high rate of infant mortality during the summer months is due to their use.

Another of the false pretenses resorted to by these reckless deceivers is the assumption of the name of some well-known benevolent association. There is one indigenous to this city that has assumed the name of an association that was organized many years ago in New Orleans specially for the purpose of mitigating the horrors of that terrible disease, the yellow fever. This mock association is a snare to our susceptible young men, who by the hundred are duped by the specious advertisements in country newspapers into the belief that for some fancied secret ailment they will find a remedy by applying to an institution conducted on such *benevolent* principles. The fool and his money soon part!

The *American Agriculturist* in each successive number does an excellent work in exposing quackery and imposture of all kinds. The various devices of our modern quacks are made so apparent that only the most willful will be deceived by them.

In a recent article on the abuses of the title "Reverend," the *New York Tribune* has the following very apt remarks: —

"We trust that respectable clergymen will pardon us if we say that the profession itself is partly to blame for the free use which is made of it (the title 'Reverend') by unscrupulous adventurers. Whether out of amiability of temper and the desire to oblige, or for some other reason less creditable, clergymen have always been too ready to lend the influence of their names to render advertisements pungent and persuasive. Almost any member of the medical faculty will testify (sometimes with tears in his eyes) that quacks and nostrum manufacturers are constantly cheating ministers out of certificates and recommendations. In respect to pills however inert, of potions however nasty, of infallible remedies, of panaceas and catholicons, ministers are the most credulous of mankind. They will discard the fine old family doctor who has gratuitously physicked and bled them for years, and take to their respectable bosoms any errant and arrant empiric whose fawning may secure their attention, and whose fluent tongue may cheat their understanding. They swallow the

mixture: their parishioners swallow the mixture. One congregation doses itself because another has; and the result, glorious and golden, is the sale of innumerable bottles of cheap tinctures and countless boxes of good-for-nothing pills at comparatively exorbitant prices — a cruel fraud if medicine be really necessary, and an insult, if it be not, to many an unoffending stomach." — *Phil. Med. and Surg. Rep.*

THE COMPOSITION OF CHLORODYNE.

Mr. Edward Smith reports, in the *Pharmaceutical Journal*, an inquiry into the composition of this well-known secret remedy. Hitherto, of the formulæ which have been published, two — one by Dr. Ogden, the other by Mr. Squire — have attracted most attention in this country. The difference between these lay essentially in the presence of Indian hemp and capsicum as indicated by Ogden, their absence in the formula given by Squire. But besides this, the proportion of morphia, as given by the two authorities, differed greatly. About the three important ingredients — chloroform, morphia, and hydrocyanic acid — there can be no doubt; no more can there be about oil of peppermint and treacle. The question is whether anything else exists in the compound. Mr. Smith thinks there is no Indian hemp, because the alcoholic extract is soluble in water; but then there is capsicum, as, after the chloroform and either, which also give pungency to the mixture, have been distilled off, the substance left behind has a hot peppery taste. He seems to have taken much pains with the analysis. Here is the result of it: —

℞ — Chloroformi, f ℥ iv.
Morphiæ mur., gr. xx.
Æther. rectif., f ℥ ij.
Ol. menthæ pip., ♏ viij.
Acidi hydrocyanici dil., f ℥ iv.
Tinct. capsici, f ℥ vj.
Mist. acaciæ, f ℥ j.
Theriacæ, ad f ℥ v.

This is not quite so dark as the original, as no caramel is used. Mr. Smith suggests for it the title Liquor Chloromorphiæ Co., as not likely to be confounded with that of any other compound.

A SIMPLE AND CHEAP STOMACH-PUMP.

Prof. John T. Hodgen, in the *St. Louis Medical and Surgical Journal*, thus describes a simple and efficient substitute for the stomach-pump: —

"About a year ago, I had a case of stricture of the œsophagus so narrow that my patient could not swallow even liquids. To sustain life, I resorted to a small stomach-tube (a gum catheter, in fact), as a means of injecting liquid nourishment; to this I fixed the elastic tube of one of Davidson's syringes.

"On one occasion the vessel containing the liquid happened to be higher than the patient's stomach, and I observed, while the syringe was not being used, that the liquid continued to flow into the stomach — the action being that of a siphon. I at once, to test the siphon, substituted a simple elastic tube for the syringe, and found the stomach could be as readily emptied as filled. Thus I conceived the idea of using a siphon instead of a stomach-pump, and have used the same in a case of poisoning recently, with the most complete success.

"I attach four feet of india-rubber tubing to a stomach-tube, fill both with water by simply dipping it in the liquid end-first, then, compressing the elastic tube between the thumb and finger to keep the fluid from running out, introduce the stomach-tube, lower the outer end of the elastic tube, and the contents of the stomach pour out as readily as if from an open vessel. When the fluid ceases to flow, I dip the outer end of the tube beneath the surface of water, elevate the vessel containing it, and the stomach is soon filled; lower again the outer end of the tube, and the stomach is emptied. This can, of course, be repeated as often as is necessary.

"The advantages claimed for this simple contrivance are, that it may be almost always improvised, is of speedy and easy application, has no valves to become obstructed or deranged, and is less expensive than a stomach-pump."

PROTOXIDE OF NITROGEN AS AN ANÆSTHETIC.

A valuable article on this subject recently appeared in the *Philadelphia Medical and Surgical Reporter*. The conclusions to which the writer arrives may be briefly stated as follows: (1) that persons breathing protoxide of nitrogen exhale a larger amount of carbonic acid than while breathing common air; (2) that its action is essentially oxidation, and that the excess of carbonic acid in the system is merely incidental, and in no wise sufficient to produce anæsthesia; (3) that its inoffensive effects are due to its action as an oxidizer; (4) that no subsequent depression follows, but rather a rapid reaction, because, acting by oxidation, the products of its combinations are speedily eliminated from the system; and (5) that its remarkably powerful action is due to its entering into new combinations, just at the moment of its liberation, when in its nascent state.

In closing, the writer expresses his "profound conviction that the pure protoxide of nitrogen, administered within proper limits, is harmless in its action, while if made from contaminated materials, if generated at too high a temperature, if used immediately after it is made, if the impurities ordinarily found in it be not removed, if inhaled in sufficient quantity to produce profound anæsthesia after being prepared for a few days, or if the administration of the *pure gas* be persisted in beyond *certain limits*, it is capable of an immense amount of mischief."

VALUABLE FORMULÆ.

Neuralgic Pill. — Dr. T. C. Osborn (*New Orleans Journal of Medicine*) gives the following as very effectual in cases of neuralgia: —

℞. Zinci cyanuret, . . . gr. vj.
quiniæ sulphat, . . . gr. ix.
morphiæ sulphat, . . . gr. iss.
ext. belladonnæ, . . . gr. iij.
Ft. pilulæ no. vj.

Dose, one pill every six hours until the pain is relieved.

Epsom Salt. — In reply to a query propounded by the American Pharmaceutical Association, in regard to the best method of disguising the bitter and disagreeable taste of Epsom Salt, Mr. Isaac W. Smith, of Philadelphia, suggests the following: —

℞. — Rad. glycyrrhizæ cont. (deprived of outer bark), ℥ iv.
Aq. bullient, Oij. vel q. s.

Mix, and allow to stand, with occasional stirring, until cold; then express through muslin, adding more water if necessary, until the residue no longer tastes; then filter, and to the filtrate add magnesiæ sulphatis, ℥ iv; finally, evaporate to dryness over a water-bath. Each ounce of the compound represents about one ounce of the crystallized salt.

Coughs. — For the harassing and annoying coughs that frequently accompany many acute diseases, and arising from nervous irritation of the larynx, pharynx, palate, or other parts of the throat, an invaluable remedy is: —

℞. Sulph. Morphia, . . . gr. j;
Dil. Sulph. Acid, . . . dr. j;
Simple Syrup, ... oz. ij.

Mix. Half a teaspoonful to be given upon the tongue, and swallowed slowly. The persistent hackings of bronchial difficulties, and even of consumption, are often speedily relieved by it.

An excellent cough mixture, for constant use the office or family, is this: —

℞. Syrup Tolu, ... oz. j;
Syrup Peru, ... oz. j;
Syrup Sanguinaria, . . . oz. j;
Syrup Lobelia, ... oz. j;
Tr. Wintergreen, . . . dr. j. M.

Dose, half a teaspoonful three or four times daily, whenever indicated.

To Preserve Pathological or Anatomica Specimens. — The alcoholic solution of corrosi sublimate is one of the most serviceable fluids f this purpose: —

Hydrarg. Bichloridum, . . oz. iv;
Alcoholicum, ... O. j.

Wash the substances well in water, immerse the in the solution and let them remain for a couple months, then take them out and dry. Animal pr parations thus treated are almost imperishable.

THE

Boston Journal of Chemistry

IS PUBLISHED MONTHLY BY

H. O. HOUGHTON & CO., Boston.
HURD & HOUGHTON, New York

TERMS, ONE DOLLAR PER ANNUM, IN ADVANCE
FIFTY CENTS FOR SIX MONTHS.

Subscriptions may commence at any time. If no special order i given, the paper will be sent from the month in which the subscrip tion is received.

Receipts. — A receipted bill will be sent by return mail to an subscriber who will inclose with his subscription a three-cent post age stamp, for return postage.

☞ Correspondents are particularly requested to give their name in full, with their Town and State; and, in case of change of resi dence, requiring a corresponding change in the mailing of their pa pers, to give, not only the new address, but the old one also.

☞ We have no complete files of Vols. 1, 2, and 3; of Vol. I (originally issued bi-monthly), we have only Nos. 4, 5, and 6 (January, March, and May, 1867); of Vol. II. (monthly), we have Nos. 2 4, 5, 7, 8, 9, 10, 11 (August, October, November, 1867, January, February, March, April, and May, 1868); of Vol. III. we have all th numbers *except* 11 and 12 (May and June, 1869). All the other numbers are out of print, and it is impossible for us to furnish them.

Of the numbers mentioned, we have a few copies left, which w will forward to our friends, at the following prices, viz.: Vol. I. three numbers, twenty-five cents; Vol. II., eight numbers, fifty cents; Vol. III., ten numbers, fifty cents. Vol. IV. and V. have been stereotyped as issued, and we are able to furnish back numbers since July, 1869, to any extent. Price, single copies, ten cents six copies for fifty cents.

TERMS FOR ADVERTISING.

Inside . . . . 40 cents per line.
Last page . . . . 60 " " "
First page . . . . 75 " " "

A liberal discount will be made upon bills amounting to fifty dollars and upwards.

Mr. George W. Hewes is our authorized travelling agent for soliciting advertisements and subscriptions.

Familiar Science.

THE WONDERS OF MICROSCOPY.

WE have a glass slide upon which, in a space less in diameter than the head of a small pin, are arranged, in perfect symmetrical order, *one hundred and four diatoms.* These wonderful vegetable or animal organisms are placed upon the glass in accordance with exact or scientific classification, and represent most of the existing and extinct species. They are not frustules or fragments, but perfect specimens, so admirably prepared that when the glass is placed under the microscope with a first-class half-inch objective, they are seen each distinct and perfect, with all the wonderful and beautiful curves, lines, and cells, which so astonish every observer. This great work of microscopic art is due to the consummate skill of J. D. Möller, a German microscopist. How he is able to accomplish this feat, is no better understood than the process or art by which M. Nobert of Pomerania is able to rule upon glass lines so fine that it requires more than 12,000 to cover the space of an inch. The little speck upon the glass in which are arranged these beautiful organized bodies, is scarcely perceptible to the naked eye; and yet, in this infinitesimal speck, the bodies are grouped with ample spaces between, and the order of arrangement and method is the same as would be observed by a scientific entomologist in grouping one hundred specimens of moths or butterflies upon a sheet of paper. In the speck, a whole volume of scientific information is embraced: it is an anatomical and palæontological museum, which can be studied only by the aid of a microscope of the most perfect construction. We have spoken of this plate, for the purpose of affording our readers some idea of the wonderful results of modern scientific skill in one department of study and research. Such facts cannot fail to awaken, even in the most indifferent, a respect for scientific investigation, and also for the investigators who are doing so much to bring to light the hidden things in nature.

WHAT SHALL WE USE FOR WATER-PIPES?

[Concluded.]

IN the October number of the JOURNAL, we had under consideration pipes for water conduction, constructed of lead, tin-lined lead, tin, and galvanized iron. We come now to consider plain

IRON PIPE.

Water, when it is brought in contact with the metal iron, oxidizes or rusts it more or less rapidly; but it is not rendered poisonous thereby. Neither the oxide, nor any of the salts of iron able to be formed from water contact, are in the least degree hurtful to the animal economy; and therefore iron conduit pipes are perfectly free from danger under all circumstances. Iron pipes are cheap, easily put in position, are free from the trouble of leakage, and are *safe.* What possible objections, then, can be urged against them? The objections relate wholly to matters of convenience and economy. The rust of iron, which sometimes is formed in considerable quantities, is liable, when the water is used for laundry purposes, to stain clothing; and this causes a good deal of scolding on the part of washerwomen and tidy housewives. Also, tea made of water containing iron-rust is changed into a pale ink; and many vegetables boiled in it are considerably discolored. These are some of the inconveniences resulting from the use of iron water-pipes; but the fact that by rapid oxidation they are often speedily filled up or destroyed may be regarded as the most weighty objection. In some localities and under some circumstances, small service-pipes rust slowly, and will continue intact for many years; under other circumstances, they are soon destroyed. Iron pipes have so many desirable points, we often advise their employment for conducting water to dwellings. No iron pipe of less diameter than one inch should ever be used; those which are smaller soon fill up, and are rendered worthless. A good way to obviate the objectionable feature of rust is to coat the interior with hydraulic cement. The Melrose and Malden Aqueduct Co., who have just introduced the waters of Spot Pond into those towns, are using a cement-lined iron service-pipe, and we predict for it entire success. It is cheap and durable, and oxidation is wholly prevented by this device. Large pipes are now successfully constructed of cement, with a thin iron pipe upon which it rests, interiorly and exteriorly. Pipes of this kind which have been several years in use, we believe, continue to afford the highest satisfaction.

GUTTA-PERCHA PIPE.

In seeking for a satisfactory material for water-pipes, the curious vegetable substance, *gutta-percha*, has been used to some extent. All metallic contamination is at once entirely avoided by the employment of this material, and apparently it has much to recommend it to favor; but, like a thousand other good things, it has objectionable features. Gutta-percha imparts to water in contact with it an unpleasant taste, and also, in some localities, it undergoes a kind of spontaneous decomposition, by which it is rendered worthless. If, however, these objections did not exist, we presume the item of *cost* would come in to drive it in a great degree from the market. At the present time we think but little of this pipe is used in any section of the country for water conduit.

BRASS PIPE.

Compound metals used for water-pipes must be looked upon with disfavor by chemists. And yet some alloys resist oxidation or other chemical change in a most remarkable manner. We know of no subject which more imperatively demands patient and careful investigation than that of *alloys.* It is a curious fact that aluminium and magnesium, when combined with each other and with other metals in certain proportions, will oxidize so rapidly as to fall into a powder almost instantly; while in other proportions the compound resists the action of oxygen to a degree approaching that of the noble metals. A mixture of copper and zinc may possibly be devised, which, when formed into pipe, will convey water safely; but of such we have no knowledge. A brass water-pipe is now being manufactured and introduced, we learn; but such should not be hastily adopted by any one.

CLAY PIPES.

The common glazed clay or "stone-ware" pipe has been used to a considerable extent for conducting water, and where the pressure is slight it may serve a good purpose. There is a difficulty, however, in securing the sections free from minute orifices which render them leaky, and also it is troublesome to form tight joints. When made of extra thickness and put in position with care, the clay pipe of small calibre may conduct water under a moderate head, for many years, with great satisfaction. That which passes through will of course be as pure as the mountain or meadow stream at its source, and this is a point of the first importance.

A CARBON WATER-PIPE,

so called, was manufactured and introduced some years since, but we have learned but little regarding its success. It was made, we think, of asphalt and sand principally, and had the merit at least, of indestructibility. The difficulty and cost of construction may perhaps have proved obstacles in the way of its production; and so it has disappeared from the market. In addition to the varieties of water-pipe described, we may name the glass and the porcelain-lined iron pipes, as worthy of notice. Iron pipe has been successfully lined with glass, and we believe the cost was not so great as to prove a bar to its general employment. Nothing could be constructed sweeter and cleaner than pipe of this nature; and we regret to learn that its manufacture has been abandoned in this city. We venture to hope that some one will resume its fabrication, and we feel assured that it might become a profitable business.

We have thus briefly and plainly brought under notice the various kinds of water-pipes which have been used; and the objectionable or desirable features of each have been pointed out.

THE CONCLUSION

of the whole matter may be presented in a few words. Leaden pipes may be employed to conduct water from ponds and rivers or open reservoirs, under *ordinary conditions*, with safety. But since disturbing agencies of a local character are liable to occur, of which water-takers can

have no knowledge until evil consequences result, it will be better to substitute some kind of pipe which is safe under all possible conditions. Neither tin-lined lead, galvanized iron, or brass pipes meet this want. Iron pipes are entirely unobjectionable on grounds of safety; and the other undesirable features which have been named are not of so serious a nature as to lead to their rejection for common use as service-pipes. By lining the interior with cement or glass, a conduit pipe is produced, which leaves a better one hardly to be desired. Block-tin water-pipes are safe and excellent, but costly. Those who do not mind expense can resort to this pipe for water conduction, with assurance that they are fully protected from danger. It is quite probable that not many years will elapse before new devices for conducting water to dwellings, which are safe and cheap, will be afforded us, as this is an important question towards which many competent and ingenious minds are turned at the present time.

CURIOSITIES OF VISION.

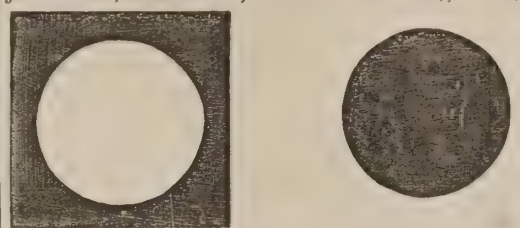
We presume that most of our readers have a general notion of the structure and working of the human eye. They know that the little sphere, of an inch or so in diameter, which forms the eye-ball is a *camera*, essentially like the one used by the photographer to throw the image of external objects upon the surface prepared to receive it and placed within the apparatus. The mere forming of this picture inside the eye is not, however, *seeing*. The picture might as well be anywhere else if there were not some means of making the mind aware of its existence. The *optic nerve* answers this purpose — a branch of the brain which enters the eye through a small hole in its rear, and spreads out in a delicate network over the surface whereon the picture is formed. The impression made by the rays of light upon this network of nerves is telegraphed to the mind, which then *sees* the object, or, rather, from seeing its image in the eye, comes to recognize the existence of the object itself outside the eye.

If the optic nerve should be severed, the picture in the eye might be as perfect as before, but we should nevertheless be blind to it. If any portion of the network of nerves just mentioned should be paralyzed, we should cease to see the part of the picture formed on that portion of the eye's inner surface. If the entire image of some small object should fall upon that insensible spot, we could no more see it, even though looking straight at it, than if we had no eyes or kept them shut. Now it is a curious fact that there *is* such a "blind spot" in every human eye; and, what is more curious, it is found to be just where the optic nerve enters the eye — the very place which we might suppose would have the keenest sight of all.

Here is a simple little experiment by which we can prove the existence of this blind spot in our eyes. Shut your left eye, and with the right one look steadily at the cross just below,

holding the paper ten or twelve inches from the eye. Now move the paper slowly toward the eye, which must be kept fixed on the cross. At a certain distance the other figure — the black dot — will suddenly disappear; but, if you bring the paper nearer, it will come into view again. You may not succeed in the experiment on the first trial, but with a little patience you can hardly fail; and the suddenness with which the black spot vanishes and reappears is very striking. Now, examination has shown that when it disappears its image falls exactly on the spot where the optic nerve enters the eye; thus proving that spot to be blind.

Let us try another experiment, which will serve to illustrate a law of light familiar enough to the scientific student, but not to people in general. Look at the black and white circles just below, and decide, without measuring them,



which is the larger. You say the white one — do you not? But if you measure them carefully, you will find that they are of just the same size. In general, when a white or bright object is seen against a black ground, it appears larger than it really is; while a black object on a white ground appears smaller than it really is. This peculiar effect is called *irradiation*, and it is due to the fact that the impression produced upon the retina of the eye by a bright object extends beyond the outline of the image.

We have a marked instance of irradiation in the case of the moon when it is a few days old. The new moon seems to be part of a considerably larger sphere than that of the old moon which it is said to "hold in its arms." The Astronomer Royal of England, Prof. Airy, has recently shown that this has led to an error in the commonly accepted measurement of the diameter of our satellite. He measured the *dark* moon, and found its apparent diameter about two seconds less than that which had been obtained by the most careful measurements of the bright moon.

Recurring to the figure, it will be noticed that the brighter the light upon the paper, the greater will be the difference in the apparent size of the two circles. If you do not see the difference well, it is because the paper is not properly illuminated, or because you hold it too near the eye. If the width of the column allowed putting the circles farther apart, it would be better. Other experiments of the same kind will readily suggest themselves to the reader.

TRAPS TO CATCH SUNBEAMS.

If the reader is not familiar with scientific treatises on the subject, it may be news to him that there are two kinds of heat, known respectively as *luminous* and *obscure*, and that some of their properties are remarkably different. Luminous heat is that which is radiated from a luminous source, as the sun, or a blazing fire, or a red-hot iron ball; while obscure heat is that which comes from any source which is not luminous, as a vessel filled with hot water, or an iron ball heated below redness. Now, it is a singular fact that these two kinds of heat have not the same power of making their way through various bodies. Luminous heat will pass readily through some substances that are quite impermeable to obscure heat; while, on the oth hand, the latter easily makes its way throug certain substances which oppose the passage c the former. Glass, for instance, is as tran parent to luminous heat as it is to light, b allows scarcely a ray of obscure heat to traver it; as you can easily prove by putting a pla of glass before a ball heated below redness, only to a dull red, and holding a thermomet on the other side of the glass. The mercu will be affected very little, or not at all. however, you substitute a plate of rock-salt f the glass, the mercury rises at once. If we di solve iodine in bisulphide of carbon, we get liquid which is wholly opaque to luminous hea but perfectly transparent to obscure heat.

The solution just described enables us to sho that luminous heat is always accompanied l obscure heat. If we let a beam of the form strike upon a thin layer of the liquid, a delica thermometer placed on the other side will ris indicating that rays of *obscure* heat have com through. Of course, these obscure radiatio must have formed part of the luminous bea As they were invisible, their existence could proved only by thus sifting them out, so speak, from the luminous rays with which th were blended.

These facts about the two kinds of heat w serve to explain why it is warmer inside a ho house on a sunny day than it is outside. T glass roof of the building allows the sunbeam with all their luminous heat, to pass through i but when they fall upon the plants and furn ture within, they are radiated back as obscu heat, and cannot penetrate the glass. They a caught in a trap, from which they cannot escap They may, to be sure, get out by *conduction* that is, by working their way, so to speak, fro particle to particle of the glass; but that is very slow process, and thousands will be e trapped while one is getting clear in that way.

The watery vapor which is always present our atmosphere answers the same purpose as t glass of the hot-house. It lets the sunbeams pa down through it; but when they are radiat back from the surface of the earth as obscu heat, it bars their progress. They cannot retu by the road they came; they are taken captiv and must stay here and work for us morta instead of flying away again, and wasting thei selves in the boundless regions of space.

We can understand now why it is warmer the foot of a mountain than on its top, thou the latter is more directly exposed to the sol rays. In the upper regions of the atmosphe there is less watery vapor to absorb the obscu radiations from the surface of the earth. W must bear in mind that the air receives t greater part of its heat, not directly from abov but indirectly by radiation from the earth belo and that the watery vapor in its lower stata like a glass roof interposed between these stra and those higher up. It is warmer beneath th vaporous canopy than above it, just as it warmer inside the hot-house than outside.

A patent has been taken out in England for hollow iron curb-stone, inside of which telegra wires may be put, instead of being buried in t earth, as is often done there. The new plan w save a good deal of labor in taking up the roa ways and pavements for the repair of the lines.

SINGULAR EFFECT OF THE SUN'S HEAT.

SOME of our readers may have heard of the singular motion of sheets of lead on roofs caused by the action of the sun's heat. In a recent English journal, we find the following detailed account of an experiment, which any one interested in the subject can very easily repeat:—

"The fact of the descent of a sheet of lead when placed upon the inclined surface of a roof, however low the pitch, especially in summer, has long been known; I myself first observed it on the southern side of the roof of the choir of Bristol Cathedral, in 1855. I have verified it by the following experiment:—I fixed a deal board 9 ft. long and 5 in. broad to the southern wall of my house, so as to form an inclined plane, and upon it I placed a sheet of lead, turning its edges down over the side edges of the board, and taking care that it should not bind upon them, but be free to move with no other obstruction than that which arose from its friction. The inclination of the board was 18° 32′, the thickness of the lead $\frac{1}{8}$ in., its length 9 ft., and its weight 28 lbs. The lower end of the board was brought opposite to a window, and a vernier was constructed which could be read from within, and by which the position of the lead upon the board could be observed to the 100th of an inch. I began to measure the descent of the lead on the 16th of February, and recorded it every morning between seven and eight o'clock, and every evening between six and seven o'clock, until the 28th of June. In the night, between sunset and sunrise, the lead scarcely descended at all. It was on days when the thermometer in the sun varied its height rapidly and much—as on bright days with cold winds, or when clouds were driven over the sun—that the descent was greatest. So remarkably, indeed, was this the case, that every cloud which shut off the sun for a time from the lead, and every gust of wind which blew upon it in the sunshine, seemed to bring it down a step. On such days it would descend from to $\frac{1}{4}$ an inch. On the contrary, when the sky was open and clear, and the heat advanced and receded uniformly, the descent was less, although the difference of the extreme temperatures of day and night might be greater. It was least of all on days of continuous rain."

THE AMAZON.

THIS great river rises in the little Peruvian Lake of Lauricocha, just below the limits of perpetual snow. For 500 miles it flows swiftly through a deep valley. Then turning sharply eastward, it runs 2,500 miles across the great equatorial plain. Two thousand miles above its mouth its width is a mile and a half, increasing to over 10 miles at the head of the delta, where it divides, and, after running 200 miles, presents a front of 150 miles upon the ocean. For a great distance it is bordered by side-channels or "bayous," as they are called upon the Mississippi, named by the Indians *igarapés*, or "canoe-paths." From Santarem, the principal town above Pará, one may paddle a thousand miles parallel to the river without once entering the stream. For twenty-five degrees of latitude every river that flows down the eastern slope of the Andes is an affluent of the Amazon. It is as though all the rivers from Mexico to Oregon united their waters in the Mississippi. A half score of these tributaries are larger—the Danube excepted—than any European river out of Russia. The volume of its waters is greater even than the breadth of the river would indicate. At Nauta, 2,200 miles from its mouth, the depth is 40 feet, increasing rapidly as it approaches the ocean. The largest ocean steamer could doubtless steam 2,000 miles up the Amazon.

The vegetation of the valley is exuberant. There is a bewildering diversity of grand and beautiful trees, a wild, unconquered race of vegetable giants, draped and festooned by creeping plants. The moment you land upon the shore you are confronted by a solid wall of vegetation, through which, if you wish to proceed, you must hew your way with axe or *macheta*. Palms, of which thirty varieties are noted, constitute the majority of trees. Then there are "cow-trees," a hundred and fifty feet high, yielding a milk of the consistency of cream, used for tea, coffee, and custards. The "caucho," or rubber-tree, though of a different species from that of the East Indies, produces a gum which constitutes most of the rubber of commerce. Agassiz puts this tree, forty or eighty feet high, in the same class with the "milk-weed" of our American pastures. Of ornamental woods there is no end. Foremost among these is the *Moira-Pinima*, or "tortoise-shell wood," the most beautiful in grain and color in the world. Enough of this is wasted every year to veneer all the dwellings of the civilized world. For many years to come the exports of the Amazon Valley must be mainly the products of its forests. Yet, strangely enough, timber is now one of the chief articles of import at Pará. A city of 35,000 inhabitants, lying on the verge of a great forest, buys pine boards from far-away Maine! This folly will in time come to an end. Contrary to all that we might expect, the climate of the Amazon Valley is temperate rather than tropical. It is more equal than in any other region of the world. Year in and year out it ranges from 74° to 87°—the fair mean being 80°.

The above facts have been gathered from Professor Orton's "The Andes and the Amazon" (lately published by the Harpers) which is the best account of this grandest of rivers and the mountain region whence it flows, that we have ever read.

THE LEAF AS A WORKER.

WHEN did the leaf begin its work? It was the *first* to rise on creation's morn and go forth to labor. Ere the almost shoreless ocean dashed upon the low Silurian plain, the leaf was at its work. And through all the long ages it has worked—worked to develop better and higher forms of life. And the earth's broad face is written all over with the evidences of its faithfulness.

Now what does it do? It pumps water from the ground, through the thousands of tubes in the stem of the tree (the tubes which itself has made), and sends it into the atmosphere in the form of unseen mist, to be condensed and fall in showers—the very water that, were it not for the leaf, would sink in the earth, and find its way perchance through subterranean channels to the sea. And thus it is that we see it *works* to give us the "early and the latter rain." It works to send the rills and streams, like lines of silver, adown the mountain and across the plain. It works to pour down the larger brooks which turn the wheel that energizes machinery, which gives employment to millions. And thus a thousand wants are supplied—commerce stimulated—wealth accumulated—and intelligence disseminated through the agency of this wealth. The leaf does it all.

It has been demonstrated that every square inch of leaf lifts three five-hundredths of an ounce every twenty-four hours. Now, a large forest tree has about five acres of foliage, or six million two hundred and seventy-two thousand six hundred and forty square inches. This being multiplied by three five-hundredths (the amount pumped by every inch) gives us the result—two thousand three hundred and fifty-two ounces, or one thousand one hundred and seventy-six quarts, or two hundred and ninety-four gallons, or eight barrels. The trees on an acre give eight hundred barrels in twenty-four hours. An acre of grass, or clover, or grain, would yield about the same result.

The leaf is a worker, too, in another field of labor, where we seldom look—where it exhibits its unselfishness—where it works for the good of man in a most wonderful manner. It carries immense quantities of electricity from the earth to the clouds, and from the clouds to the earth. Rather dangerous business transporting *lightning*. I think it would be considered contraband by the "U. S.," or "Merchant's Union," or any common carriers; but it is particularly fitted for this work. Did you ever see a leaf entire as to its edges? It is always pointed, and these *points*, whether they be large or small, are just fitted to handle this dangerous agent. These tiny fingers seize upon and carry it away with ease and wonderful despatch. There must be no delay; it is "time freight." True, sometimes it gathers up more than the *trunk* can carry, and in the attempt to crowd and pack the baggage the trunk gets terribly shattered, and we say that lightning struck the tree. But it had been struck a thousand times before. This time it was overworked.—*American Entomologist.*

THINGS WORTH NOTING

TO RENDER WOVEN FABRICS INCOMBUSTIBLE.—The tungstate of soda has long been known as an excellent article for this purpose, but the tungstate of ammonia answers the purpose even better. A concentrated solution of this salt is to be diluted with water to the specific gravity of 1.140. The goods are moistened with the liquid just before starching, and they can then be ironed and finished without the least difficulty. The most delicate colors are not injured by the process. Cloth thus prepared cannot be set on fire; it may be charred by intense heat, but not ignited. For muslins and children's dresses, and especially for the dresses of ballet-dancers, nothing could be more convenient or more efficient as a protection against accidents from fire.

CHEAP MOSQUITO BAR.—A correspondent of the *American Entomologist* writes: "There is a mosquito bar in vogue among the plantation hands and boatmen in some parts of the South, which answers every purpose to the letter; it is common petroleum. A small quantity is dropped on a piece of cotton, and then squeezed out as dry as possible, after which the cotton is rubbed over the face and hands. No mosquito will alight where the scent has been left. I have tried it, and then exposed myself to clouds of them, on various occasions, without experiencing the least annoyance."

HARNESS BLACKING.—An English scientific journal gives the following as a composition that has been thoroughly tested, and which keeps leather (of boots and shoes, as well as harnesses) in excellent condition:—

2 oz. best white wax, $\frac{1}{2}$ oz. Prussian blue, $1\frac{1}{2}$ oz. ivory black, $\frac{1}{4}$ pint of spirits of turpentine, 1 tablespoonful spirits of wine. Melt the wax, over a slow fire, in an earthenware vessel, then add the blue and black, taking care to put in the black gradually at first, or it will boil over; when cool, add the spirits. Stir it well from first to last. After applying it to the leather, polish with a soft cloth or brush.

OLD RIBBONS RENEWED.—Wash in cool suds made of fine soap, and iron when damp. Cover the ribbon with a clean cloth, and pass the iron over that. If you wish to stiffen the ribbon, dip it, while drying, into gum arabic water.

HOW TO CLEAN OIL-CLOTHS.—If you wish to have them look new and nice, wash them with soft flannel and lukewarm water, and wipe perfectly dry. If you want them to look extra nice, after they are wiped drop a few spoonfuls of milk over them, and rub them with a dry cloth.

The Arts.

BROMINE.

A VERY good illustration of the curious fact that increased consumption of an article lessens its price is afforded in the case of the element *bromine.* Five years ago it was sold in this country and in Europe as high as eight dollars a pound; now the price is less than a dollar and a half the pound, and the consumption has increased in a thousand-fold ratio. As a manufacturer of chemical substances, we did not have occasion to purchase for manufacturing purposes twenty pounds a year until after 1865, when a great demand sprang up for the bromides of potassium, sodium, and ammonium. Some idea of the increase in consumption may be formed from the statement that we have ordered of the salt-makers in Pennsylvania quantities as large as five thousand pounds, or *two and a half tons*, at one time, during the past year. Our bromine supply formerly came from Germany, the Stassfurt salt-mines furnishing it in considerable quantities after they were opened; but now our own strong salines in Pennsylvania, Ohio, and West Virginia produce it in amounts fully equal to the demand. It is indeed a singular element, very closely allied to iodine in its characteristics, but having different medicinal properties. The two salts, bromide and iodide of potassium, are consumed in vast quantities in medicine. The method of manufacture is nearly the same, the salts resemble each other very closely, and yet the effects upon the animal economy are entirely dissimilar.

NOTES OF NEW INVENTIONS.

NOVEL SEA-GOING VESSEL. — The model of a sea-going vessel of very original build is now to be seen in the port of Algiers. A general idea of the construction is obtained if we imagine a steamer cut in two, and the severed parts made the support of a bridge four times the length of the original vessel. This bridge has an air-chamber in its entire length, so that if by accident it should become parted from the supports it cannot be submerged. It is destined for the cargo, but cabins in the form of boats are so arranged along the sides of the bridge that, in case of accident to this latter, they may be navigated separately. Thus there are three chances of safety if the construction goes to pieces. The supposed advantages are great speed (since, the larger part of the vessel not being in contact with the water, the resistance is so much diminished,) safety, and great space for cargo.

OBTAINING HIGH TEMPERATURES. — A very useful invention of Mr. Coffey is now to be seen in operation at Messrs. Doulton and Watts's, of Lambeth. It is a new mode of obtaining high temperatures for the evaporation of liquids without the use of high pressure or superheated steam, and is, in fact, a modification of the circulating system, heated water being replaced by heavy paraffine oils. These circulate exactly like water. A close system being made, the oil heated in a coil of pipe placed in a furnace rises first to an air-tight tank, from which it runs through pipes and the jackets of pans, descending as it cools to the coil of pipe in the furnace. With this apparatus a temperature of 600° or 700° F. may be safely maintained without any of the risks arising from the use of steam at high pressures, and, as will be easily seen, with a much less expenditure of fuel. A pyrometer is contrived to show the exact temperature of the oil as it leaves the tank, and means are provided for regulating and keeping the temperature uniform.

NEW METHOD OF PURIFYING WATER. — It is claimed that metallic iron affords the readiest and simplest means of disinfecting water and of keeping it fresh. The water of the Thames, taken to sea in iron tanks, soon becomes perfectly sweet and remains so during a long voyage. A small piece of iron or a few nails in the water in which cut flowers are put will keep the water sweet. The experiment has been tried of putting some iron filings in a vessel with a very small quantity of water and then placing a leech therein. After six months had passed, the water was found quite fresh and the leech alive and healthy. These facts are curious and suggestive.

LIGHTING GAS BY WATER POWER. — A Mr. Hunter, in England has invented what he calls a "hydraulic gas-lighter." By one operation the tap is opened, a match struck, and the gas lighted. A service pipe is to be laid throughout the district to be lighted, with branches to each lamp. The pipes are charged with water, and the pressure required is given and maintained from a tank placed at the required elevation. Inside each lamp post is to be placed a small cylinder, to the piston of which is attached a rod. The top of this rod is serrated, and gears into a toothed wheel attached to the plug of the lamp tap, which is turned round and opened as the rod rises. A small fusee drops from a reservoir, and is carried by a swivel plate to a piece of roughened spring on which it is rubbed and ignited. It is then carried round past the burner, the gas is lighted, and the fusee drops to the bottom of the lantern. In the morning, when the gas is to be extinguished, the pressure of water is taken off the cylinders, and an escape tap opened, the pistons drop with the weight of the rod, and the taps are turned off. It is proposed that as the lamps are cleaned weekly, the lamp cleaner shall supply the reservoir with a week's supply of matches.

RENDERING GOODS WATER-PROOF.

THE *Manufacturer's Review*, which is excellent authority on such matters, gives the following methods of water-proofing goods, in addition to those published in our August number: —

1. *Impregnation with Caoutchouc.* — Take 100 grammes of a concentrated solution of caoutchouc in turpentine, and 30 grammes of alumina, and mix the two substance well together. The cloth is laid upon a table, the mixture spread over it, and permitted to dry, The thickness of the covering of course depends upon the number of coats put on. If the reverse side is changed in any way, it is cleaned with alcohol.

2. *Water-proof "Double-Stuff."* — The principal peculiarity of this fabric is the joining of two waterproof tissues without preventing the passage of the air, with the aid of any of the mixtures already described, or of the following preparation: 2 gallons of water, $1\frac{1}{3}$ pounds of powdered (burnt?) alum, and $1\frac{1}{8}$ pounds of white lead. These are mixed, and after the white precipitate formed has settled, the clear liquid is decanted, and the goods immersed in it till they are thoroughly impregnated. They are then placed into an ordinary soap-bath, washed with pure water, and dried. Next in order comes the application of caoutchouc by spreading the solution in *oblique* stripes upon the cloth, and producing similar stripes on the cloth which is to be laid upon the first, but in such a manner that if the two are put together, these stripes shall cross each other at right angles. Small squares are thus formed, which allow the air access and the perspiration to escape, without the rain being able to penetrate through the double cloth.

3. *Preparation for Cotton, Linen, Silk, and Woolen Goods.* — This preparation, which is free from smell, and resists mordants, contains principally alum and carbonate of lime. It is prepared as follows: Dissolve 222 pounds of crystallized alum in 24 gallons of water, and add 88 pounds of carbonate of lime (chalk), add after this $3\frac{1}{2}$ pounds of sandarac which has previously been dissolved in alcohol, mix the whole, allow it to settle, decant the clear solution, and apply it at a temperature of 140–160° F.

MEMORANDA IN THE ARTS.

CHINESE GOLD LACQUER. — The gold-lacquer lining of a Chinese cabinet in the Museum at Cassel peeled off, and thus gave Dr. Wiederhold the opportunity of studying the composition of this substance. On examining it he found particles of tinfoil attached to the lacquer, so he comes to the conclusion that this material formed the ground upon which the lacquer varnish was laid. His attempts to imitate the varnish were perfectly successful, and he gives the following directions for the preparation of a composition which closely resembles the true Chinese article. First of all, two parts of copal and one of shellac are to be melted together to form a perfectly fluid mixture, then two parts of good boiled oil, made hot, are to be added; the vessel is then to be removed from the fire, and ten parts of oil of turpentine are to be gradually added. To give color, the addition is made of solution, in turpentine, of gum gutta for yellow, and dragon's-blood for red. These are to be mixed in sufficient quantity to give the shades desired.

PRESERVED BREAD. —Preserved bread has been suggested by M. Maurice as a substitute for biscuits for the use of sailors, soldiers, and travellers. The bread is made in the ordinary way, and is then thoroughly dried. It is afterwards exposed to high pressure steam for a short time, and is subsequently submitted to hydraulic pressure to reduce the bulk. The cakes so produced will keep, it is said, for years, if protected from moisture. They are necessarily hard, but are masticated as easily as biscuits. The process by which these cakes are made is long and troublesome, and the only advantage that they can possess over biscuits consists in the circumstance that they have undergone the primary fermentation which some writers on dietetics allege to be absolutely necessary to produce bread of a perfectly wholesome character.

IRON AND HYDROGEN. — A curious observation has been made by M. Caron on an alteration produced in iron when it is kept melted for some time in an atmosphere of hydrogen. The metal increases somewhat in density, and becomes soft and malleable as copper. Re-melted in a crucible it becomes scaly when cold, doubtless in consequence of the evolution of absorbed hydrogen. Are we to regard the softness and malleability as the properties of an alloy of hydrogen and iron?

THE FIRST LOCOMOTIVE. — The French claim the honor of having constructed the first locomotive. It was made by one Crugnot in 1760, the same eventful year which saw the birth of Napoleon I., Wellington, Humboldt, and several other celebrated characters. The first engine is still preserved in the Conservatoire des Arts et Métiers at Paris.

LIQUID ALLOY OF SODIUM AND POTASSIUM. — Melt together four parts of potassium (which fuses at 122° F.) and two and a half parts of sodium (fusing at 194° F.) This mixture, which has the appearance and consistency of mercury, has its point of solidification at 47.40° F., and is consequently liquid at ordinary temperatures. It is prepared under naphtha.

ECONOMICAL PAINT. — Skim milk 2 quarts, fresh slacked lime 8 oz., linseed oil 6 oz., white Burgundy pitch 2 oz., Spanish white 3 lbs. The lime to be slacked in water, exposed to the air,

mixed in one fourth of the milk; the oil, in which the pitch is previously dissolved, to be added a little at a time; then the rest of the milk, and afterwards the Spanish white. This quantity is sufficient for 27 square yards, two coats.

CHEAP AND FINE VARNISH FOR WOOD. — The beautiful varnish which is applied to Connecticut clock-cases, wooden picture-frames, and other cheap objects, is in appearance equal to the elaborate finish of the finest furniture, such as pianos, etc. It is made by mixing two pounds of copal varnish with half an ounce of linseed-oil varnish. The mixture is shaken often to mix it well, and is then placed in a warm spot. The wood to be varnished is prepared with a thin coat of glue-water, dried slowly, and rubbed down with fine pumice-stone or something equivalent. In light-colored wood, a light pigment, such as chalk, is added to the glue-water; in dark wood, an equally dark pigment is added. When ready, the articles are varnished with the above mixture, and, after drying, rubbed with a solution of wax in ether, thus getting a high polish.

Agriculture.

SHORE PENCILINGS AT LAKESIDE, NO. 3.

THE cool winds and the hoar frosts of the autumn months have aided in the sad work of stripping the trees, shrubs, and grasses of their rich summer attire, and they are now for the most part standing cheerless and bare. Here and there a late-blooming flower may be seen, or a narrow patch of green grass in some warm sheltered nook, on the margin of the lake; but the great and active operations of Nature in building up and sustaining vegetable structures have ceased, and soon a snowy mantle will be cast over field and wood, and the deep sleep of winter will commence. The corn, wheat, and other grains, with the roots and grasses, have been safely housed; and notwithstanding the extreme drought, most glorious crops have been secured. The farm-work of the summer months is ended; and the herds seek shelter in barns, the squirrels in trees, and the birds take flight to a sunnier clime. We must imitate their example, and flee from our lake-shore retreat to the library or parlor, where the genial heat from the blazing wood in the open fire-place dispels all feelings of sadness or discomfort, and puts us in a mood even to welcome the reign of snow and ice. As we look out upon the bare fields this morning, we are led to pencil down some thoughts upon the *winter life of plants.* It is an error to suppose that in winter, in our climate, there is a dead calm in plant life, and that Nature is wholly palsied in her movements. Wherever the rays of sunlight fall, there is never perfect rest; and this relates to the vegetable as well as to the animal world. Sunlight is pregnant with life, no matter how slant may be the rays, or how few the hours during the twenty-four they may fall upon the earth. In winter the really useful plants cannot grow, but in the lower forms of cryptogamic plants the processes of vegetation are quite active. The mosses, lichens, liverworts, etc., resist cold wonderfully, and they will grow at very low temperatures. We find them under snow-banks and sheets of ice in winter, keeping up an active circulation, so active that they are able to ripen their sporangia or mature their fruit, with the thermometer close upon zero. Lichens are so constituted as to be able to reverse the order of nature, and take their winter nap in summer. In the cold months their vegetating period occurs, and they are then most active. The lichens are a very low order of plants; but we must not look upon them with contempt, for from their existence, or by their creation, life upon our planet is rendered possible. The poor, humble lichens came before man; and man would never have come at all, if the lichens had not preceded him. These plants are the very first which made their appearance upon the rocks, when our earth was barren and chaotic; and dying there, they prepared the way for a higher vegetation. At the present time there are few rocks so barren or smooth that the tenacious lichens will not fasten upon them, and flourish through storm and cold, as do the cereals in the best of soils and in the warmest sunshine. Suppose the reader becomes interested in these statements, and starts out botanizing some day in the coming winter months. Such an excursion will by no means be devoid of interest or instruction. Everywhere on rocks, fences, and fallen trees, and in the pebbly bottoms of brooks, the rich mosses will be found in great variety; and their study will open up new ideas of the wonderful nature of plant structures, even in their lowest forms.

But activity in plant life in winter is not alone confined to the cryptogamia. It is during this inclement season that many of our forest trees ripen and perfect their seeds. The firs and pines are not like the deciduous trees, which allow the moisture they contain to freeze in winter. The temperature of a pine-tree under the bark never falls below the congealing point, no matter how severe the cold may be outside. These resinous trees keep up a kind of low "tree heat," as do the bears a low animal heat, in freezing weather. Consequently the circulation of sap goes on, and the immature seeds are ripened. In some localities in the northern part of our country, those evergreens grow which bear true leaves, like the ivy, laurel, or perhaps the holly. We call these plants evergreens; but in fact they change their leaves as do the deciduous varieties. The change is made gradually, one leaf dropping off when another has grown to replace it, and so the tree is never wholly deprived of its foliage. It is probable that in winter there is considerable vegetative activity in these evergreens, as it is impossible that these changes can take place when the sap is completely dormant. Sunlight and warmth are agents of tremendous power in connection with plant activities. If in the depth of winter a mild day occurs, we shall find, by making incisions in the stem or branches of trees, that the slumbering forces are partially awakened, and the sap is in motion.

If we allow that in the higher orders of flowering plants winter is a time of repose, it can hardly be supposed that there is no interchange of matter between the air and the body of the plant, for some such movement is needful to its life. The hibernating animals in their dens are practically dead, but still a feeble form of life remains; the heart slowly beats, and waste goes on. There is, in fact, a continuous interchange of particles between the air and the body, and so there must be between the air and all plant structures. Men and animals sleep during the night-time, but the functions of life go on undisturbed. Winter to deciduous trees and herbaceous plants is their night-time, when they sleep, to recuperate their vital energies, and become prepared for the labors of reproduction when the spring opens. As is the case with human beings, it is better that this sleep be continuous and undisturbed, in order that full strength may be had for work in the season of activity. A winter in which there are many fitful changes, first warm and then cold, is unfavorable for the growth and perfection of seeds and fruit; and trees and plants suffer more from these causes than from drought or wet in summer.

We have spoken of the trees as being bare of foliage in winter; but this is not absolutely true, for trees have winter leaves as well as summer leaves. The winter leaves are less apparent, but they are no less real or perfect. If we take from a tree one of its buds, and examine it carefully, we shall see that it is composed of a little bunch of true leaves, nicely compressed together in layers, resembling fish-scales. These are the winter leaves of trees, and every species has them perfectly characteristic of its kind.

This winter dress of trees is no apparel suddenly formed, or put on late in the autumn; it is the growth of all the spring and summer months. During the hot season, when the sap is active, it was diverted away from the buds, by the great demands of the expanding summer foliage, so that their growth was slow. They remain immature until the summer leaves begin to fall, when the sap flows towards the buds, and they are perfected. The winter dress of trees has a purpose in the economy of plant life. The structure in winter does not demand nutrition, but it must have protection, and this the buds afford. In them is stored up all the beauty and glory of the vegetation of the coming year, and thus they possess an interest of the highest kind. Nature is very careful of these buds, for it seems to be understood that in them exist latent forms of life, most intimately connected with the welfare of the race. In order fully to protect them, they are compressed together very tightly in the smallest possible space, and are covered in under an air-tight and water-tight roof. The outer layer of buds is either covered by a warm coat of fine hairs, or cemented closely with a resinous or glutinous secretion, which resists the action of water. How wise and careful is Nature in all her wonderful operations! Can we doubt for a moment the existence of a great and good Being, who guides and directs all these movements?

But we perceive that the great interest of our topic is leading us along into a field which is almost boundless in extent. We would like to walk awhile longer therein, if we were sure our readers would follow us with the enthusiasm which we cannot help feeling ourselves. If they desire to accompany us another day on a similar excursion, we will perhaps look more closely into the winter life of plants.

TREE PLANTING. — The State of Iowa planted, last year, about 15,000,000 trees, and will set out a still larger number this year. Two farmers, in one township, have set out this spring 25,000 trees. This is at the rate of about five trees, annually, for each inhabitant — none too many to meet the demand for fruit, commerce, fuel, and timber.

ARTIFICIAL BUTTER.

HAS the chemist's skill attained to such results as enable him to manufacture the delicious and important food substance known to us as *butter?* This is an interesting question. Through recent foreign advices we learn that M. Méye, a Parisian chemist, is actually making good, palatable butter out of a variety of animal fats, by a process which is patented in nearly all the countries of Europe. His claim is that by subjecting sweet lard or other animal fats to great pressure, by which the stearine is extracted, an oily material is obtained, the composition of which is identical with butter. After obtaining this "oily material," he subjects it to a variety of chemical processes, which result in securing the flavor and physical characteristics of prime butter. The patent specifications and claims are presented with much detail; and the reader who is interested in butter necromancy is carried along through all the steps by which unsophisticated grease becomes sophisticated fat, and ultimately butter, of a character which would pass unchallenged through the hands of a first-class St. Albans butter inspector. This is certainly very important scientific intelligence, if true; but we are not yet ready to break up or burn up our churns, and send our cows to the butcher. We prefer to wait for further advices. Butter is a delicate animal compound, which, in our view, cannot be fabricated or imitated successfully by any chemical processes whatever. Doubtless a substance can be produced which may serve as a fair substitute for butter among certain classes in Europe; but the fastidious taste of large consumers, both in that country and in this, can never be satisfied with butter coming from other sources than the sweet grasses of the hills and meadows, or from the cereal grains, transmuted or changed by the subtle chemistry of the animal organism. In this connection, we cannot help remarking that the present aspects of chemical science and research are wonderful and interesting in the highest degree. The attempts which are being made to construct organic bodies of the most delicate and complex nature seem almost presumptuous, or perhaps audacious. In an article which will be published shortly, we shall bring under review the triumph of chemistry during the past decade in that department which relates to organic substances.

LARGE GRAPES.

THE party of editors who examined our graperies at Haverhill on the 20th of September expressed surprise, not only at the size of the bunches, but at the size of the berries. We have been led to measure some of them, and find that we have Golden Hamburgs measuring $3\frac{5}{8}$ inches in circumference, and Black Hamburgs $3\frac{3}{8}$ inches. The clusters on some vines weigh nearly two pounds. These vines are five years old, and their vigor and productiveness can hardly be surpassed. *Quality* in grapes is an important feature that producers and consumers often overlook, both in those raised in cold houses, and out of doors. The saccharine qualities and the fine flavor of grapes are greatly enhanced by proper and favorable methods of cultivation; and we hesitate not to say that one pound of Black Hamburgs or Frontignacs produced by our methods of fertilizing the borders is worth more than two grown under ordinary conditions. Our method is to supply to vines little or no excrementitious manures, but to depend upon those chemical or special agents which enter so largely into the structure of both vine and fruit. Upon this our success in grape culture depends. In a future number of the JOURNAL we will present the details of this method, as we believe the matter is of interest to all engaged in the delightful and profitable work of cultivating vines.

THE ROSTIEZER PEAR.

IN remarking upon pears and grapes in the last number of the JOURNAL, we stated that the Doyenne d'Eté was the only early variety of pears worth raising in this section. In saying this, we certainly did injustice to that delicous little pear, the *Rostiezer*. We have a half-dozen trees of this variety, which, the present season, filled many a hand-basket with the rosy-cheeked morsels. The Rostiezer, in our view, is a better pear than the Seckel, which it resembles in many points. This is saying a great deal; and as it matures its rich juices before the "dog-days" commence, we must reckon it among the earliest varieties. The tree is tolerably vigorous, with long, branching limbs; and the fruit grows in clusters, numbering a half-dozen or more. It needs a good, moderately moist soil and careful cultivation. As regards trimming, when on quince stock, we say "let it alone;" and this we say of nearly or quite all the varieties of dwarf pear-trees. We have had a sad experience in following the instruction of wise men who presume to give advice regarding the trimming of pear-trees. Lop off those branches which grow inordinately or abnormally, and leave the rest to nature. This advice comes from experience. Those of our readers who have space for the cultivation of but a few varieties of pears should include one or two Rostiezers in the collection, as they are indeed an early and delicious fruit.

NOTES FROM ABROAD.

VINE LEAVES AS FODDER. — It is stated by *Les Mondes*, that in France vine leaves and the cuttings of young vine twigs are largely used in a green state as fodder for cattle, and are also partly salted for winter forage. This new utilization of material will furnish food for large numbers of cattle in vine-growing countries.

OZONE FROM PLANTS. — Professor Mantegazza, of Milan, has shown that the cultivation of our common herbs and flowers is worth something more to us than arises from the pleasure they give to the senses of sight and smell. They are in reality great store-houses of health, since they evolve quantities of ozone, which is developed by the direct action of the sun's rays, and, in some cases, continues to be evolved during the dark. Lavender, cherry-laurel, narcissus, hyacinth, and mignonette are mentioned as among the most valuable of these ozone makers. Professor Mantegazza suggests that great benefit would be derived from planting these and other herbs and flowers in marshy and unhealthy districts.

BEET-ROOT CULTIVATION IN PRUSSIA. — The raising of the beet for sugar manufacture has extended very rapidly in Prussia. Be ween 1836 and 1870 the production had increased a hundred fold. The increase in the yield of sugar from a given weight of the roots has also increased; it used to be five per cent., but is now nearly seven per cent.

WAR AND AGRICULTURE. — The *Journal de l'Agriculture* computes that the losses of the French farmers in the districts invaded by the Prussians amount to more than *eight hundred millions of dollars* (in gold). More than ten millions of acres have been overrun, and the loss of crops and cattle cannot be reckoned at less than eighty dollars an acre. It will be a long while before the country will recover from the evil results of this exchange of the sword for the ploughshare.

COLORS OF FLOWERS. — An English writer says that "the three primary colors, red, blue, and yellow, are not to be found pure in any species of flower." Thus we have red and blue in the fuchsia, but no yellow; yellow and red in the rose, but no blue; blue and yellow in the pansy, but no red; and so on. If this is universally true, it is certainly very curious. According to Helmboltz and other modern authorities, however, the three primary colors are red, *green*, and blue, and not red, *yellow*, and blue, as maintained by Brewster.

GRAPE-VINES.

"HAVE YOU A CHOICE GRAPE CUTTING THAT YOU WANT TO GROW? — Then go to the woods, dig some roots of a wild vine, cut them into pieces of about six inches long, cut your choice grape-vine or cutting into pieces of only one, or at most, two buds; insert the lower end by the common cleft-grafting method into the piece of wild vine root, plant it in the earth, leaving the bud of the cutting just level with the top of the ground. Every one so made will grow, and in two years become bearing plants."

The above is a clipping from an old newspaper, and concisely describes the process of manufacturing grape-vines, successfully tried with the root of an old Isabella vine in Pawtucket last November.

Our woods are full of wild grape-vines, and there are tons of choice cuttings which must necessarily be clipped from valuable cultivated vines this winter. Now, let every one who wants a grape plantation, and who cannot afford to purchase the best early varieties, go to his neighbor in November, and ask him for trimmings of Concord, Rogers's Hybrids, Delaware, or other most desirable *early* vines; then let him provide himself with a grape-vine root, either wild or of some hardy garden variety like the Isabella, — ripening too *late* to be valuable here, — and proceed to graft and plant as above.

But, after having planted and left the bud of the cutting just level with the top of the ground, do one thing more. Cover the bud with a mound of earth a foot high for the winter, and carefully uncover it in the spring. Or, if you choose, invert over the bud a very small flower-pot, cover this with a handful of straw, and bury the whole for the winter under a pile of earth. C.

CHEMICAL FLORICULTURE. — A correspondent of *The English Mechanic* mentions as a novel fact that the common hydrangea (*Hydrangea hortensis*) has flowers of a pale blue color in Cornwall, but when transplanted to another part of England produces pink blossoms. We have noticed the very same change of color in the flowers of this plant here in Massachusetts when removed from one soil to another only a few miles distant. The writer just mentioned was led to try the effect of certain chemical substances upon the hydrangea, and found that by mixing iron filings with the soil in which it grew, he was able sometimes, but not always, to change the pink of the flowers to blue. Cuttings taken from plants thus changed, and grown without the iron filings, invariably went back to the original color. He thinks that this is a solitary instance of such a change in a plant produced by chemical means. Can this be true?

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

SCIENCE AND WAR.

Two of the most scientific nations of the world are now engaged in a horrible war; and all the aid which modern chemistry and engineering skill can furnish is enlisted in the dreadful work of destroying human life. This is completely reversing the great ends for which science is or should be prosecuted. It is the proper mission of science to prolong life, and to render human beings happier whilst they live. But war, that demon of the bottomless pit, neutralizes everything that is good and humane in this world. It ruthlessly seizes hold of every secret thing or process which science extorts from nature, and by the aid of which mankind can be rendered more distressed and miserable, and uses it in unstinted measure day and night. In both France and Germany, all scientific research, except in one direction, is suspended. The eminent *savans* are all engaged in devising new and more dreadful agents of destruction, or in efforts to ward off or mitigate the effect of blows received. The world has yet to find a better or more efficient agent of destruction than the old compound of charcoal, sulphur, and nitre. Some of the monks and ecclesiastics of mediæval times thought that gunpowder came to us through the suggestions of the devil; that it was no discovery, in any proper sense, but simply a diabolic revelation of the nature of an infernal mixture. In these more enlightened or less superstitious times, we are led to regard the discovery of gunpowder as a remarkable accident. It resulted from no scientific deductions, for they had no science. No one had any knowledge of the fact that a mixture of the three ingredients of gunpowder, when touched by a spark, would be instantly decomposed, forming a large volume of gases, of vast elastic force. Science had nothing whatever to do with the discovery of gunpowder; and the hypothesis of the monks, referring it to diabolic agency, is quite unsatisfactory to us heretics. The discovery of pyroxyline or gun cotton, and the series of explosive bodies of similar chemical constitution, was no accident, but came through the natural channels of scientific deduction. So also of nitro-glycerine, dualine, and that class of bodies of which we have recently heard so much. These new and terrible agents of destruction do not appear to play a very conspicuous part in the operations of either the French or German combatants. The reason is, that they are of such unstable character that they are dangerous to friends as well as foes, and also they can only be used under conditions which are not often favorable in war. So far as field operations go, it may be proved that gunpowder of fair quality, used in connection with an old "King's-arm" musket, is a better "armament" for ordinary soldiers than "sharp" powder with needle guns or Chassepot rifles. Battle shooting is, most emphatically, random shooting. In some of the recent engagements, it is reported that several of the French regiments exhausted seventy rounds of ammunition to a man, without, so far as could be learned, killing a dozen of the enemy. It would be a curious result, if, after all that science has accomplished in improving gunpowder and guns, the world should go back to cheap powder and smooth-bore muskets. Sharp-shooters are undoubtedly of great service in the field, and they require the best and most accurate weapons; but the rank and file may do better with arms that do not afford facility for very rapid or accurate shooting. As regards the great German chemists, they are just now very much engaged in fabricating or devising disinfectants to ward off disease in the crowded camps and hospitals. Hofmann writes to England, in the most imploring tone, begging the chemists there to send over ship-loads of carbolic acid, chloride of lime, permanganate of potassa, etc. He thinks the camps will soon become "hot-beds of contagious diseases," unless they are thoroughly disinfected. Let us hope that this useless, disgusting, cruel war will soon close, and that science may be turned from the arts of war to the arts of peace.

MAN AND MONKEYS.

PROF. GILL, at the Troy meeting of the American Association for the Advancement of Science, read an elaborate paper "on the Relations of the Orders of Mammals," in which the following is given as the conclusions of his researches upon the natural history of man: —

"There is scarcely a proposition in biology more demonstrable than *that man is the derivative from the same immediate stock as the higher anthropoid apes*, and probably after the culmination to nearly the same extent as at present of the differentiation of the order into families and subordinate groups."

This will do for Prof. Gill; and with such beliefs he must permit us to congratulate him upon his illustrious ancestry. Now, will he inform us if it is true that apes were changed into human beings from biting off each other's caudal extremities in some fierce encounters in a remote age? This is a favorite theory, or belief, with some speculative gentlemen; and if he will present his views upon it, another important "biological" question may be removed from the field of controversy.

THE TESTING OF KEROSENE.

IN a former article on this subject, we referred to some of the criticisms made by eminent English chemists upon the mode of testing petroleum oils prescribed in the act of Parliament. In the recently revised act, which appears to have been prepared with much care, new and more minute directions are given for applying the "flashing" test. As they are of general interest, we reprint them in full from the official text: —

"The cup which is to hold the oil shall be of thin sheet iron or of metal blackened on its inner surface; it shall be two inches deep and two inches wide at the opening, tapering slightly towards the bottom; it shall have a flat rim projecting from the edge of the cup, by which it shall be supported in a metallic vessel four inches and a half deep and four inches and a half in diameter; it shall also have a wire stretched across the opening, which wire shall be so fixed to the edge of the cup that the upper side of the wire shall be a quarter of an inch above the upper side of a circular wire, which shall be fastened round the inside of the cup a quarter of an inch below its upper edge. The thermometer to be used shall have a round bulb about half an inch in diameter, and shall be graduated upon the scale of Fahrenheit, every ten degrees occupying not less than half an inch upon the scale.

"When the instrument is to be used, the petroleum to be tested shall be poured into the cup till the liquid rises just to the upper side of the circular wire. The outer vessel shall be filled to within an inch of its edge with water, and a small flame shall be applied to the bottom of the outer vessel. When the temperature of the water has risen to 80°, the cup which contains the oil to be tested shall be placed in the outer vessel, and the thermometer shall be inserted into the oil, so that the bottom of the bulb shall be immersed about one inch and a half beneath the surface. A covered screen, blackened on the inside and provided with a hole in the cover for the passage of the stem of the thermometer, shall be placed over the apparatus, and shall be of such dimensions as to surround it about two thirds, and to reach about eight inches above the level of the vessels. The temperature shall be raised gradually, so that it shall require about five minutes to raise the oil from 80° to 95°.

"When heat has been applied to the water until the thermometer has risen to about 90° Fahrenheit, a very small flame, such as that from a piece of burning twine, shall be passed quickly across the surface of the oil, on a level with the wire. If no pale blue flicker or flash is produced, the application of the flame is to be repeated for every rise of two or three degrees in the thermometer. When the flashing point has been noted, the test shall be repeated with a fresh sample of the oil, using water at a temperature of 80°, as before, withdrawing the source of heat from the outer vessel when the temperature approaches that noted in the first experiment, and applying the flame test at every rise of two degrees in the thermometer.

"N. B. — In performing the test, the operator must be careful not to produce any current of air which would remove the vapor from the surface of the oil, either by breathing upon the surface or by any sudden movement."

SULPHITE OF LIME. — This article, which Prof. Horsford suggested fifteen years ago for arresting the fermentative process in cider and wines, has continued to grow in favor ever since. With its use, good cider can be preserved for many months in a sweet and palatable condition. It is easy to use, and perfectly safe. Messrs J. R. Nichols & Co., of this city, chemists, are the only parties who sell the genuine article, as prepared by Prof. Horsford.

MOVEMENT OF MICROSCOPIC GRANULES.

I HAVE just read the article by Mr. C. T. Wake, in the October number of the JOURNAL, "on the effect of heat on organic germs." The article is very interesting, as a confirmation of the theory of spontaneous generation, or it proves that experienced microscopists like Mr. Wake can make mistakes. It is not credible that organic germs could have retained vitality after exposure to the heat which he applied to the milk; it is not credible that eggs of infusoria like *kolpoda* could have been in the milk, if that had not been exposed to the air; and it is to be presumed that Mr. W. would not have experimented on milk that had not been protected. Is there any other source of error? Mr. W. says he put the burnt "residue" in a bottle half full of distilled water — size of bottle not given. Now I have shown in this JOURNAL that I had found it impossible to procure distilled water perfectly pure. What germs were in the distilled water the experimenter did not know. Like hundreds of others, he takes it for granted that there can be none, and then attributes everything he discovers to the matter experimented upon, and not to the medium used. But what did he find besides the kolpoda-like animal? Something like *amœbæ*, an object about the nature of which very little is known, and a "mass of organic matter" which "had attached to it great numbers of small infusoria, which, by continual jerking movements, endeavored to free themselves." Here is where I believe the great mistake of eminent microscopists has often been made, probably in part owing to inferior instruments. They have assumed that a body with a "jerking movement," or any movement, must be an infusorium, or a germ, or some organic being. This is the important point now for the study of microscopists. In August of this year, Mr. D. S. Holman, of Philadelphia, brought to me a slide which he wished examined. It was placed under the microscope with a *good* objective, and I saw the field filled with an immense number of minute spheres, all in movement, as lively as a party in a ball-room. I at once saw that they were what I think have been called monads by some writers, germs by others, and "bioplasm" by Beale. Mr. Holman then informed me that what I saw was albumen — white of eggs — coagulated by carbolic acid; that it was prepared, mounted, and completely sealed up from access of air, in July, 1869; and that the lively movement had been going on constantly (at least it was always seen when looked at) ever since. I can add that it is going on up to the present time. A few days since, with the view of verifying Mr. Holman's experiment, I prepared some white of egg myself, and have obtained the same results. The whole field of the microscope is filled with minute granules, particles, monads, or germs, all dancing together. Now here we have matter in which it is impossible (if human reason can pronounce an opinion on the subject) that any animal or vegetable life can exist, and yet in which there is present that one evidence of life, motion; and this motion has continued in the first-mentioned slide unchanged for fifteen months. Nor is this all. I have prepared slides of inorganic matter, — *e. g.*, minute particles of chalk and china clay, suspended in a solution of glycerine in alcohol (can any life be sustained in such a medium?) — and these not only present the same movements, but an expert eye cannot distinguish a particle of organic from one of inorganic matter, with the same magnifying power. This movement of particles of matter in a fluid is no new thing; it has been known for years, and the text-books on the microscope all caution novices against being deceived by it; yet I have good reason for thinking that many who are experts have been so deceived. For a continued exhibition of the phenomenon, I believe it to be essential that the matter should be so near the specific gravity of the fluid as to remain in suspension. In the case of chalk and of clay, the particles in time settle in contact with the glass, and then are motionless until dislodged by jarring them.

C. S.

THE SUMMER OF 1870.

PROF. LOOMIS, of New Haven, gives in the *College Courant* a summary of the meteorology of the past summer, from which it appears to have been a very remarkable season, both for its high temperature and the small amount of rain. Meteorological records have been kept at New Haven from 1778 to the present time, and the past summer was the hottest known in all that time. The next hottest was that of 1780, the mean temperature of which was about three quarters of a degree below that of 1870.

By means of observations made less than a hundred miles from New Haven — at Newport, Rhode Island — this comparison can be extended fifteen years further back, to 1763. The hottest summer during this period was that of 1773, the mean temperature of which was just the same as that of 1870. If, however, we take the *four* months, June, July, August, and *September*, we find that they have averaged hotter this year than for any year since 1763, a period of 108 years.

The deficiency in the amount of rain is quite as remarkable as the high temperature. After giving a tabular statement of the amount of rain for the first nine months of 1870 compared with 28 preceding years, Prof. Loomis remarks: "It will be seen that in January we had considerably more rain than usual; but since that time each month has shown a deficiency, which in eight months amounts to twelve inches. For the past five months, the deficiency is 10.76 inches; that is, the aggregate fall of rain has been *less than half the average*, while the temperature has been *the highest known for more than a century*. The fall of rain for the past five months has been less than for the same months in any year embraced in the record. It is not strange, then, that this vicinity should have suffered from drought, and it is only remarkable that the injury to vegetation should not have been more serious than it has been."

CURIOSITIES OF NAMES. — In looking over the long list of physicians who are subscribers to the JOURNAL, we have been quite amused at the curious names of some of them. We have upon our books *Dr. Death*, *Dr. Slaughter*, *Dr. Dye*, *Dr. Coffin*, *Dr. Toombs*, and *Dr. Graves*. This sombre list is lighted up by one *Dr. Life*, one *Dr. Strength*, and *Dr. Joy*. Dr. Drinkwater just balances Dr. Rumn on the liquor question; and Dr. Grant and Dr. Lee are doubtless as successful in fighting disease with pellets and powders as certain other gentlemen of the same names have been in fighting other kinds of battles with *bullets* and *powder*. We have equal confidence in the skill of Dr. Death and Life, and believe them both to be intelligent, worthy gentlemen; for otherwise they would not be patrons of our JOURNAL.

OUR PROSPECTUS. — We solicit attention to the new prospectus of the JOURNAL, which may be found in the advertising department of the current number. Our friends have certainly been very kind in obtaining new subscribers, for which we desire to express thanks. The JOURNAL, with a united effort on the part of its readers, may soon become the most widely extended publication in the world, as it is now the best patronized of the journals of science. Reader, please hand this number to a neighbor, and ask him to subscribe. You will thus do both him and us a service.

EDITORIAL NOTES.

CEMENT WATER-PIPE. — In our articles on water-pipes we omitted to direct attention to a form of pipe constructed wholly of hydraulic cement. It is very cheap; and when it is desired to construct aqueducts for supplying barns, stables, and private establishments, nothing can be better. It is formed by digging a trench below the frost line from the spring or reservoir, and then using a flexible rubber hose pipe, of the desired capacity, as a *mould*. Cover it with cement, of an inch or two in thickness; and as it hardens, draw it along, adding fresh covering of cement until the whole line is completed. In this way an expert workman will construct many rods of the pipe in a day, and it will cost comparatively but a trifle. This pipe is very strong and durable, and conducts water without any deleterious contamination.

A SEVERE TEST FOR A LIGHTNING ROD. — A powder magazine at Venice, containing 300,000 kilogrammes of gunpowder (about 300 tons) was struck by lightning this summer. The platinum point of the lightning-rod was melted, and the rod split and twisted, but the electric charge was safely conducted to the earth without doing any other damage. That lightning-rod may be said to have saved a city, for the explosion of such a quantity of powder would have laid all Venice in ruins.

A FOOL'S PERSISTENCY. — The truth of Solomon's assertion as to the result of the pulverization of a fool in a mortar was admirably illustrated in England not long ago. A Mr. John Hampden, of Swindon, offered the scientific world a wager of £500 that the surface of water was perfectly level. The wager was accepted by a man of no less note than Mr. A. R. Wallace. The trial was carefully arranged, and Mr. Wallace was of course successful in demonstrating a distinct convexity of the water of the Bedford Canal between two points selected by the parties. The arbitrator handed over the stakes to Mr. Wallace, and we might suppose that Mr. Hampden would be wiser as well as poorer for the experience. Not a bit of it. On the contrary, he publishes a pamphlet, of which the following is the title-page: —

"*Is Water Level or Convex after all? The Bedford Canal Swindle Detected and Exposed.* The Controversy ended, as all such impious frauds must end, in victory for truth, and the defeat and disgrace of those who oppose it. 'Knowest thou not this of old, since man was placed upon the earth, that the triumphing of the wicked is short, and the joy of the hypocrite but for a moment?' — JOB xx. 4, 5. Swindon: Alfred Bull, Printer, Victoria Street. 1870."

In this precious production, which will doubtless be immortalized in some future "Curiosities of Literature," he uses more of invective than of logic, and abuses without stint all the parties concerned in deciding the wager against him. Of Mr. Walsh, the editor of the *Field*, who was the referee, for instance, he says: — "Take these editorial functionaries away from their scissors and paste-pot, and they are found to be as great blockheads as other men — mere slaves to the popular taste, and most of them as venal as any hireling in existence. There is no doubt some moral or pecuniary pressure was brought to bear on the late decision, and, like all cowards, Mr. Walsh was afraid to uphold the truth, and the palpable evidence of the reports against the array of scientific opinion which he knew would be down upon him in the event of his giving judgment favorable to the anti-Newtonian theory." He speaks of scientific men as a class who, "next to horse-dealers and jockeys, bear the reputation of being the most tricky and unscrupulous in their assertions;" and generally he speaks of Mr. Wallace, by implication, as a liar, a cheat, and a swindler.

It will be noticed that the pamphleteer puts a scriptural motto on his title-page; but we cannot

help thinking that a more appropriate one would have been the aphorism of Solomon's to which we alluded in the beginning of this note.

LUNAR HEAT. — Some recent observations upon this subject have been made in Paris, by M. Baille, at the Ecole Polytechnique, and M. Marié-Davy at the Paris Observatory. The former employed a concave mirror of 39 centimetres aperture to condense the moon's rays upon his pile, and also made use of a Thompson's galvanometer. The one conclusion at which he arrived was, that the full moon, at Paris and in the summer months, gave as much heat to his pile as a radiating surface 6.5 centimetres square, maintained at boiling-water temperature and placed at a distance of 35 metres.

CHEMICAL TRANSMUTATIONS. — Linen can be converted into sugar; sugar into alcohol and carbonic acid; alcohol into ether and water. Sugar can also be converted into oxalic acid; and likewise into pure charcoal and water. Alcohol will readily change into acetic acid, or vinegar. Coal-tar is transformed into dyes that surpass the Tyrian purple of old. Starch may be transmuted into gum, alcohol, sugar, vinegar, or oxalic acid; and these are but a few of the magical changes which modern chemical science has made "familiar as household words."

LAWS GOVERNING DISTILLATION. — Volatility alone does not determine which of mixed liquids will distill over first. Quantity has something to do with it. If the less volatile be in large excess, it tends to come over with the other. But there is still another law. The comparative density of the vapors produced affects the result; the denser vapor having a tendency to be evolved in greater quantity. Dr. Van der Weyde thus closes an article on this subject in *The Technologist:*

"These facts prove that the amount of vapor developed from liquids is regulated by volume and not by weight, or, in other words, that of two liquids possessing the same boiling point, but of which the densities of the vapors differ, the same volumes of vapors will evolve, and that, consequently, the liquid emitting the densest vapor will evaporate in larger quantity; or that if there be two liquids of which the boiling points differ, and that with the lowest boiling point possesses the lightest vapor, the greater volume of the vapor generated from the latter will produce less liquid after recondensation than the lesser volume of the vapor evolved from the less volatile liquid, the latter thus more than compensating the former, and resulting in the apparent anomaly that from a mixture of two liquids of different boiling points, the least volatile may sometimes distill over in the largest quantity."

CLEANSING SOLUTION.

A VERY cheap and simple fluid for removing grease-spots from woolen clothes may be made by dissolving one ounce of crystallized carbonate of ammonia (the sesquicarbonate) in one pint of water. Scour the woolen fabric with a piece of cloth or sponge wet in this solution. It is not necessary to follow the solution with water, or to do anything but let the cloth dry spontaneously. As the sesquicarbonate of ammonia of the shops is apt to have lost part of its ammonia and to have become an inert bicarbonate, we advise adding to the above solution one drachm (a teaspoonful) of aqua ammonia.

Made thus, the preparation does not really cost, *for materials*, more than three or four cents a pint, though, of course, it costs more to prepare and dispense it. But a grease-spot removed by it never reappears. Of the hundred preparations for this purpose which we have made and tried, none has ever been so efficacious. C.

COTTON-SEED OIL AND SPONTANEOUS COMBUSTION.

THE president of one of our large insurance companies sends us the following note: —

"The JOURNAL OF CHEMISTRY recently contained an article on cotton-seed oil, in which you speak of its being used for adulterating olive-oil. I wish to inquire if cotton-seed oil is not dangerous, as specially liable to spontaneous combustion. A large manufacturer in this vicinity informs me that he has abandoned the use of olive-oil because he has had several instances of spontaneous combustion occur from the use of it as adulterated with cotton-seed oil. Your articles on kerosene oil have been very valuable to insurance companies, and you will confer further favors upon them and the community by giving your views upon the above points."

REMARKS. — We suppose our correspondent wishes to inquire if cotton-seed oil, when used in connection with rags, cotton waste, saw-dust, etc., is not liable to cause spontaneous combustion. No oils by themselves in quantity will ever spontaneously ignite. They must be spread about or subdivided so as to present to oxidizing agencies a large extent of surface, as they do when cotton fibres or saw-dust are saturated with them. As regards cotton-seed oil, we have not yet been able to subject it to experiment; but we think it is much more dangerous than animal oils and fats, or olive-oil. Linseed-oil has been regarded as the most hazardous; but we judge from its nature, and the source from whence it is derived, that cotton-seed oil is equally dangerous.

We think many more fires are caused through the agency of oily rags than is generally supposed. Painters, grainers, and varnishers should be watched constantly by builders and owners of buildings who employ them, as they often throw oily rags into dark corners, where they spontaneously ignite and cause serious conflagrations.

LITERARY NOTES.

THE Harpers have published an *Index to Harper's New Monthly Magazine*, Vols. I. — XL. An examination of its pages will show the encyclopædic comprehensiveness and variety of the forty volumes. For those who can afford to buy but few books, the set furnishes quite a complete "Family Library." It would not be easy to find anywhere else so much good reading at so moderate a cost.

We are informed that the same house will soon publish Shakespeare's *Merchant of Venice*, edited with Notes by W. J. Rolfe, A. M., formerly Head Master of the High School, Cambridge, Mass. It is to be handsomely printed and illustrated, so that it will be a very pretty little book, even if it has no other merit. It is intended for household reading, as well as for educational use.

Messrs. Scribner & Co. have completed their cheap reprint of Froude's *History of England* with Vols. XI. and XII., and Mommsen's *History of Rome* with Vol. IV. The latter contains an excellent Index, which gives it a decided advantage over the English edition. Two new volumes of the "Library of Wonders" have also appeared: *Light-houses and Light-ships*, and *The Wonders of Acoustics*. The former appears to have the English wood-cuts, which are very good, and is every way commendable; the latter is quite inferior in its illustrations, — apparently cheap copies from the French originals, — and the mechanical execution generally is below the average of the series. We note some palpable misprints, as "rat" for "ut" in the old Latin Hymn of St. John, from which the names of the musical notes were taken.

In giving an account of buildings badly constructed for acoustic purposes, the author says: "In the Church of St. Paul, Boston, which has the same defect, the preacher's voice *can only be heard once a year*, on Christmas Day, when it is decorated in such a way that the arches are less sonorous." For the sake of the worshippers at St. Paul's, we hope that this statement of the case is not literally exact.

Notices of several other books are unavoidably deferred.

THE DEVELOPMENT OF SPECIES BY NATURAL SELECTION.

WE hear a great deal about this "theory of natural selection," which is gaining general acceptance among scientific men; but many people have very crude notions concerning it. The doctrine, concisely stated, is simply this: that all the varied species of plants and animals have been developed from a few simpler forms by natural processes; that the surrounding conditions of climate, etc., produce modifications, and those are perpetuated which suit the varied conditions. In other words, nature does just what man does when he produces new varieties. Some people are terribly afraid of the doctrine, because they suppose that it dispenses with creative action; whereas it really teaches that the creative power is everywhere present, acting now and forever, instead of acting once for all. Rightly understood, it teaches, as the great Teacher taught, "that the sparrow falls not to the ground unheeded by its Father and ours; that each springing seed, each blade of waving grass, and the humblest insect, whose life is but a summer day, is part of a great whole pervaded by the universal life, of which these different forms are the actions and development."

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers*.

S. J. S., MEDFIELD, MASS. "Since putting in the galvanized iron pipe, our tea-kettle is lined with an insoluble grayish white crust, after boiling the water in it. . . What is this powder?" It is probably carbonate of zinc, which has been removed from the zinc covering of the pipe by the action of carbonic acid upon the metal. The same morning on which your inquiry was received, *three other* instances of like character came to our knowledge. It is quite time this miserable business of using galvanized iron pipes for water conduction was stopped.

S. C. T., BRANDON, VT. A leather strop used for improving the cutting qualities of razors does not accomplish that end so much by wearing away the hard steel as by adjusting the edge, so that it can act directly upon the beard. The fine edge of a razor, when examined by a microscope of high power, resembles a *saw*, the teeth of which are jagged and irregular. The strap adjusts these thin bits of steel, so that they stand in line, and they then can *saw off* the beard with greater facility.

J. T. K., HADDAM, CT. The enlargement of the tonsils in children is a very common affection, and should excite no uneasiness. The operation of removing them is by no means severe, not so much so usually as extracting a tooth. Sometimes astringent gargles will afford relief; but if the difficulty is chronic or persistent, removal is the only cure.

M. R., CONCORD, N. H. You should correspond with *Messrs. Lebosquet Bros. of Haverhill, Mass.* This house constructed the wrought iron furnace used by us last winter, and the work gave entire satisfaction. As stated in the last JOURNAL, we have confidence in their skill and integrity, and no other parties will be likely to construct it as well. They have had experience, and now possess all the facilities for its manufacture.

H. B., INDIANAPOLIS, IND. Your inquiry is of the character of hundreds which we receive, and to which we cannot reply. The information you seek is solely for your personal benefit, and therefore we can give it no consideration.

A. O. N., writes us from Norway, Me., as follows: "In my family we use water drawn through 100 feet of galvanized iron pipe. Since it was put in, the whole family have been troubled with *very sore mouths*. It appears different from common canker, having a more extended and severe inflammation. Is this due to the galvanized iron pipe?" Probably the zinc salt formed in the water is the *chloride*, which has *caustic* properties of ex-

traordinary character. The affection of the mouth which you describe is precisely what we might expect to result from using water containing minute quantities of chloride of zinc.

F. C., Springfield, Mass. To present fully the methods of detecting adulterations in cider, vinegar, spices, and articles of food, would require the space of a book. We have only room in the Journal for brief explanations.

C. W., Tully, N. Y. The ashes from blacksmiths' shops are coal-ashes, and have no more fertilizing value than the same kind of ashes from other sources. They are worth but little.

J. O. W., Chicopee, Mass. The *jute* used so generally by the ladies in the place of hair is probably not very liable to become infested with animal life, and yet such instances have occurred. One marked case has come to our knowledge, and caused the lady great inconvenience and alarm. If we belonged to the "better part of creation," we would not pile this fibrous material upon our head, even if it is fashionable to do so.

D. N., Jackson, Mich. No; rain-water is not so well adapted to culinary use as spring-water. Rain-water is very nearly pure, and pure water is not adapted to the wants of the system. Wash your floors and clothing in rain-water, but seek spring or pond water for drinking purposes.

E. M. A., Ripley, Miss. The hydrate of chloral does not appear to produce injury when long continued, and in most instances it does not lose its hypnotic effects. Still, we do not approve of taking any kind of medicine longer than it is absolutely needed.

J. V. D., St. Lawrence, Wis. All the chemical substances for removing superfluous hair from the face are uncleanly, and often produce disagreeable effects upon the skin. We know of nothing which we should be willing to recommend for the purpose.

F. A. M., New Sharon, Mo. The specimen you send of an article sold to the farmers of your section, for "improving cattle, horses, sheep, hogs, etc., and for increasing the milk of cows," is mostly composed of *ground linseed.* It has a little bitter principle added, which appears to be that of *gentian.* Linseed is excellent for improving the condition of animals, and promoting a flow of milk; but when you purchase it of a charlatan, who charges "$3.00 for a box holding five pounds," you are certainly *cheated.* Now, we appeal to your common sense, is it not preposterous to suppose that any "peddler" or other person can furnish a substance in a *five-pound package* worth $3.00 for feeding to animals? Farmers and others must not be so *easily duped.* They must not allow their hard earnings to be filched from them by designing men. Use a little "common sense."

B. M. A., Potsdam, N. J. Salt is of no use to soils when used alone. Indeed, in our experience its application has injured the crops.

D. E. T., Rouse's Point, N. Y. Hydrate of chloral undergoes change, if mixed with water and other substances, and is allowed to remain for several weeks. For use in the case of infants, the crystals may be dissolved in anise-seed cordial, or some other pleasant aromatic.

J. W. A., Pawtucket, R. I. Flax-dust from flax-mills, we think, must have considerable fertilizing value. It is certainly worth experimenting with.

J. B. L., Fort Smith, Ark. The deposit of black oxide of manganese to which you refer may become of some value if the use of oxygen increases. At present the article is so cheap in the market, it will hardly pay to open up new sources of supply.

S. B., Deerfield, N. H. Kerosene barrels cannot be cleansed so as to be suitable for cider or any other beverage. — We prefer to apply top dressing on grass lands, early in the spring.

L. M. D., Northampton, Mass. The seed-corn we furnished to several farmers last spring, and we learn that it has proved very satisfactory. We did not suppose that it had any special excellences; but we think from our own great success in corn-raising, and that of others who used the seed, that it is worthy of attention as an early and prolific variety. We call it the "Boardman" corn, from the name of the gentleman who furnished us the seed. Our corn crop the present season has ripened splendidly, and the ears are perfect. We can furnish you, and any of your neighbors, with what seed you may want for next season's planting, at the price seedsmen may fix upon.

D. E. B., Portland, Me. If proper care and skill are exercised, cider can be manufactured of a quality equal to the best of wine. In the first place, make it late in November, so that the fruit may ripen; second, cast out of the heap all that are decayed, and then with a hose-pipe, if you have water-head, wash the apples clean. Grind fine, press, and barrel the juice the same day. Strain it into the casks from the press, through coarse sand — the layer three or four inches thick. Put the casks into a moderately cool place, and watch the fermentation. As soon as the first fermentation is completed, and when the cider is sparkling and sweet, add to each barrel four ounces of isinglass, or fish-glue, dissolved in one gallon of warm cider. Turn it into the bung-hole, leaving ample space for it. (At least two gallons should be drawn from the cask.) What is known as "Cooper's" isinglass is the best. At the end of a month, the cider will be ready to bottle, or to rack off into a sweet clean cask for use. The tap should be about four inches from the bottom of the cask in drawing off, and all below rejected. If the cider is not drawn off, put into the cask six ounces of sulphite of lime (Horsford's) after fermentation. This will keep it sweet.

Medicine.

WHO IS TO BLAME?

We recently made a brief call upon a first-class apothecary in a neighboring city, who does a large prescription business. The clerks and proprietors were busy behind the counter making up prescriptions from shelf bottles, apparently with as much indifference to the responsibilities of the work as the farmer engaged in digging his potatoes or husking his corn. Everything was working smoothly, until one of the clerks was observed to put down the bottle which he held in one hand, and take the prescription which he had in the other to the proprietor, when, after a short consultation, the work was resumed, and the prescription completed. We begged permission to look at the prescription. It read as follows: —

℞. — Elix. Proprietatis . . . ℥ij.
Aqua . . . . . . ℥ij.

The inquiry made by the clerk was, whether the word "aqua" *meant* water or "something else." He was told it meant *aqua ammonia*, and that agent was used in the mixture. This procedure seemed to be so much a matter of course that we ventured to inquire if such liberties were often taken with prescriptions, and the reply was, "Yes; we often have to correct physicians' blunders, and we are obliged to *guess* at their meaning very often." "In substituting ammonia for water, what *strength* of the agent did you use?" we asked. "Oh, the *common* strength.' We did not venture to make further inquiries, although perplexed to think that after an experience of twenty years in manufacturing the agent, we were ignorant of the nature of that of "*common* strength." Now, as regards this prescription, it is hardly presumable that the physician meant to add *water* to the tincture of myrrh and aloes, although that was demanded. Obviously the document was *carelessly* written, and the word "ammonia" omitted. Assuming that the apothecary was right in his *guess* at what was meant, how improper and dangerous is the custom of taking such liberties! Then, again, look at the recklessness of using aqua ammonia of *unknown strength.* It might have been of 26° B., or it might have been of but 3°. This case illustrates the carelessness of the physician on the one part, and the boldness or recklessness of the apothecary on the other. We have good reasons for believing that such instances are by no means rare; and in view of the serious consequences which have resulted and which are liable to result from them, we are led to ask, Who is to blame?

The druggists as a class in this country are wonderfully sagacious, and cannot be excelled in quickness of perception; but they learn the "trade" too imperfectly. The basis upon which rests the fabric of American pharmacy is indeed peculiar. The free-and-easy way in which our young men without education, without proper qualifications, slide into the business of the apothecary is one of the singular things in this singular country. There are no laws regulating pharmaceutical matters; nobody inquires into the qualifications of those who come forward, "open shop," and presume to dispense medicines. The business, so far as the public and we may say physicians concern themselves, is unfortunately on a par with other departments of trade.

It is a matter of regret that we have no schools of instruction of a sufficiently high an reputable character, to which young men ca resort and fit themselves for the duties o the profession. There are plenty of "Col leges of Pharmacy," so called, in almost ever city and large town; but they are of a char acter hardly to command attention or respect What is needed are schools with teachers of high order, men who are thoroughly acquainte with practical science in all its branches. Th course of instruction should be as thorough an systematic as a college course of study; and thos who cannot learn pharmaceutical chemistry i its practical details should not be allowed to as sume the duties and responsibilities of an apoth ecary. The occupation is an honorable one, an it needs to be elevated to a position where i will command the confidence and respect ac corded to the learned professions.

There is too much truth in the statements o apothecaries that many physicians are hardl competent to prescribe properly. The educatio of medical men is very defective; and in ac quaintance with medicinal agents and skill i prescribing, the druggists are often their superi ors. They acknowledge this by leaning upo them, and in being influenced and controlled b them. A physician, to be qualified properly t discharge the duties of his profession, shoul thoroughly understand the physical and chemica character of drugs. He should be able promptl to detect sophistications, and judge of the qual ity of medicinal agents. Chemistry and phar macy are very superficially taught in our medi cal schools. But little practical information i imparted in this direction. The time of study is too limited, and the standard of requirement is too low. And then again, in prescribing by written order there is unnecessary haste an carelessness, and often the chirography is s abominable that it is liable to be misunderstood It may be that an entire revolution is needed i the methods of prescribing for the sick. Ther are very grave evils connected with the presen plan, and it is easy to conceive of a better. W have some decided views upon these points which we may express at a future time.

CASES TREATED WITH HYDRATE O CHLORAL.

The Journal has so wide a circulation that it i probably read by more physicians than any othe medical publication. This is my excuse for sendin you this record of some cases treated with *chlora* I received an ounce from J. R. Nichols & Co., and judging from its effects, should think it a reliabl preparation.

An elderly lady, since dead, was suffering fro malignant disease of the stomach, with stricture o the œsophagus. The pain and nervous disturbanc were so great that she could get no sleep. Wit great difficulty of swallowing she took 20 grains o chloral in syrup. In less than half an hour she wa sleeping soundly, and breathing naturally. Sh slept seven hours, and woke refreshed, and wit no untoward symptoms. As she soon left the plac to enter a hospital in Leavenworth, I had no op portunity of repeating the remedy.

The next was a case of deep interest, and migh be called a *test case.* A married lady, thirty-seve years of age, and highly nervous organization, ha for years been subject to attacks of convulsions which, from the history, I suppose to be hysteric So severe were they that it took several persons t

ld her, and they lasted several hours, leaving her ıch prostrated. In former attacks she has been rtially controlled by chloroform. I learned that ere were always well-marked premonitory sympms, and, being in attendance on a sick child of rs, recommended that chloral be procured, and 20 ains in syrup be administered on the occasion of e next attack. It was but twenty-four hours be-e all the symptoms showed themselves. The loral was administered, and in a short time she ept. All nervous disturbance disappeared, and in c hours she woke, feeling refreshed and well. hough this was six weeks since, she has as yet had return of attack.

I am now giving the chloral to a child of five ars for epilepsy. There is a distinct aura, man-sted by pain in the top of the head. As soon as e first symptoms appear, she takes eight (8) grains syrup, — she sleeps for from three to seven hours, ring which the nerves are quiet, and she wakes though nothing was the matter. Since she has ken it, now four weeks, there has been but one veloped paroxysm, and that was in the night, and e symptoms, instead of appearing from once to ice a day, are from four to five days apart. I ve great hope that by persistently watching and lowing up the treatment, and thus arresting the roxysms, the system will fully react, and a radi-l cure result. BENJ. WOODWARD, M. D.

WYANDOTTE, Kansas.

ERYSIPELAS.

My attention has been drawn to an article in the URNAL entitled "A Specific in Erysipelas," ac-edited to *Medical and Surgical Reporter.* I n testify as regards the "*specificity*" of one of e ingredients entering into the combination recom-ended by Dr. Garretson, to wit, sulphate of inine. In the May number of the *New Orleans Medical and Surgical Journal* for 1867, I contrib-ed an article on erysipelas, in which I spoke of inine as the remedy *par excellence* in that disease. y method of using it is by inunction, covering the flamed parts thickly by an ointment made by com-ning sulphate of quinine with lard, taking up as ıch of the quinine with the lard as possible. My actice with it has been uniformly successful. ery likely the muriated tincture of iron would be good adjunct, as the tincture of cinchona certainly ould be, acting as additional tonics.

The opinion advanced by me in the article al-led to was that erysipelas originates from a cryp-gamous plant of the order *Fungi* which I desig-ted as *fungus erysipelatosus.* This plant distrib-es its sporules, which take root only on a soil, so speak, adapted to its growth.

I have noticed such a resemblance between the flammation of erysipelas *per se* and that produced the poison oak, that I am led to the belief their igin is the same. In this section of the country Central Louisiana) the poison oak grows abun-ntly. Erysipelas is very common here, and in most stances it is difficult to distinguish it from the in-ammation produced from the oak. Indeed, there nothing to distinguish the latter, except the fact actually having come in contact with the oak, and the inflammation making its appearance immedi-ely afterwards. Inunction with quinine readily res the poison from the oak.

The same rules which govern in erysipelas gov-n also in inflammation from the oak. The oak is obably milder; and while it may not be identical th erysipelas, it is probably a species of the same der. I speak exclusively of the poison, taking the ound that is a parasite belonging to the oak.

The sulphate of quinine acts by destroying the tality of the sporules; and if the doctrine of Dr. alisbury of Ohio be correct, that malarial disease iginates in the same way from a cryptogam, then the theory of quinine destroying the vitality of the sporules will apply to its remedial effect in intermittents.

I would remark *en passant* that the hydrate of chloral I obtained from your laboratory is the most perfect medicine in its way I ever used.

J. F. GRIFFIN, M. D.

EVERGREEN PARISH, La., *September* 22, 1870.

TINCT. FERRI CHLOR. IN ERYSIPELAS.

DR. T. TEMPLE, of Amherst, Mass., writes as follows regarding the use of this remedy: —

"In the September number of the JOURNAL OF CHEMISTRY is an interesting article taken from the *Medical and Surgical Reporter*, entitled "A Specific in Erysipelas." Permit me, if you please, to say through your columns that I have used the muriated tincture of iron as an external remedy during the last eight years, and with the same uniform success that Dr. Garretson claims for his formula of Tinct. Ferri Chlor. combined with Tinct. Cinchonæ and Sulph. Quiniæ, though not with such instantaneous relief as he represents in his cases. I have long been convinced that the Tinct. Ferri Chlor., as an external remedy, was far superior to Tinct. Iodine or Nitr. Silver, which have been so extensively used heretofore in that dreaded disease. The late Dr. Gray of Springfield, Mass., was a firm believer in the Tincture of Iron treatment for Erysipelas, and used it, both externally and internally, with the most satisfactory results. Whether the combination of Cinchona and Quinine with the iron adds to its efficacy, or not, is a matter that may need to be determined. The effects of the muriated tincture alone as an external application have been entirely satisfactory, so far as my experience is concerned; and the testimony of other physicians who have used it confirms my own. I think it is as nearly a specific for Erysipelas as any remedy known is for any other disease. If any of my medical brethren who give the remedy a thorough trial, desire to return to the old plan of treatment again, their experience will be worth relating."

INTRATISSULAR INJECTION OF CHROMIC ACID FOR THE DESTRUCTION OF TUMORS PROBABLY MALIGNANT. — In the *Philadelphia Medical and Surgical Reporter*, June 18, 1870, Dr. Daniel Leasure of Alleghany City gives an account of a tumor of the neck (probably malignant) treated by the injection of chromic acid. It was situated on the right side, one inch and a half by two inches and a half longest diameter. On the 17th September, 1869, it was injected by a hypodermic syringe with sixty drops of a solution of chromic acid, 100 grains to the ounce of water.

On the day following and on the third day it was injected as before. No serious irritation. On the 30th September repeated, the tumor softening. 17th October, the same. 15th November, the tumor had collapsed. An opening formed, and matter was discharged. Poulticed, and on November 29th, reported well. There was a small cicatrix, three lines in diameter, at the seat of the late opening, which so closely resembled in color the surrounding skin as to be scarcely noticed. In June, 1870, no sign of return. Two other similar cases treated with like success. The use of chromic acid in this manner is new. Acetic acid was suggested by Dr. Broadbent, but with unsatisfactory results. We look on Dr. Leasure's report with the greatest interest, deeming the action of chemical substances on living heterologous tissues a subject yet unexplored, still of very great promise of usefulness. *

The anatomist who has discovered a new muscle in the human body has taken out a patent, and no one can use the muscle without paying royalty.

MEDICAL MEMORANDA.

THE good results of compulsory vaccination in Ireland are shown by the fact that there was but one death from small-pox in the whole island during the last three months. — A foreign medical journal recommends chewing the leaves of the olive tree as a remedy for laryngitis. — Eight cents is the regular fee of a "regular" Chinese doctor in his native country. — A recent royal decree permits women to practice medicine in England, after passing the ordinary examination.— Dr. Ballot, a Dutch physician, prefers buttermilk to sweet milk for infants that cannot be nursed by the mother; it is boiled for a few minutes with a little wheat flour and sugar. — The *Pharmaceutical Journal* recommends, as a good general excipient for pills, two drachms of powdered tragacanth and six drachms, by measure, of glycerine, mixed in a mortar. It soon becomes a firm, tenacious mass, which keeps well, and but a small quantity is required, even with such substances as quinine or iodide of potassium. Pills made with it do not become hard. — In Vienna, opening abscesses under water, and applying plaster of Paris, is being tried with satisfactory results. — Kerosene oil is recommended as an antidote for bee-stings; and, according to other authorities, it is an excellent application for burns and scalds. If the liquid can be used to neutralize a part of the mischief it causes, let us be duly grateful. Will our homœopathic friends claim it as an instance of *similia similibus?* — By order of govenнment, the chief alkaloids of Peruvian bark have been tested in India in 2,472 cases of fever; and the result, as stated in the *Medical Times*, is that the sulphate of quinidia has an antifebrile power equal to the sulphate of quinia; that the sulphate of cinchonidia is slightly less efficacious; and that the sulphate of cinchonia, though inferior to the others, is a very valuable agent in the treatment of fevers. — A Prussian chemist has devised a process for detecting *strychnia* by saturating the suspected substance with ammonia, and allowing it to dry spontaneously; then heating it with a little amylic alcohol, and adding a few drops of the liquid to sulphuric acid and bichromate of potash; when, if strychnia be present, the well-known coloration characteristic of the alkaloid will be obtained. —In Birmingham, Eng., a druggist named Weston was fined 20 shillings for neglecting to have his child vaccinated; and W. D. Hall, a "herbalist and anti-vaccination lecturer," for a similar offense, was mulcted in the same amount. The magistrates also ordered the children to be vaccinated. — We find the following useful hint in the London *Chemist and Druggist:* "As it is of importance in the use of lunar caustic to have it free from all infecting matter from previous use, I took some common matches, and cut off the igniting portion; I then dipped their ends into lunar caustic, melted; by so doing, I obtained what I called caustic matches, which enabled me to use a fresh piece of caustic daily, free from infecting matter, which would not be the case if the same piece of caustic were used repeatedly, and not carefully cleansed. Besides which, this plan enables a minute point of caustic to be ready at any moment when required."

POPULAR SUPERSTITIONS IN ENGLAND.

A clergyman, writing to "Notes and Queries," gives the following sketch of a dialogue between himself and an old dame of his parish: —

"*Parson* — Well, Dame Gray, I hear you have a charm to cure the toothache; come, just let me hear it. I should be so much pleased to know it.

Dame — O, your reverence, it's not worth telling.

[Here a long talk — parson coaxing the dame to tell him — old lady very shy, partly suspecting he is quizzing her; partly that no charms are proper

things; partly willing to know what he thinks about it.] At last it ends by her saying —

"Well, your reverence, you have been very kind to me, and I will tell you: It's just a verse from Scripture as I says over those as have the toothache: 'And Jesus said unto Peter, what aileth thee? And Peter answered, Lord, I have toothache. And the Lord healed him.'

P. — Well, but Dame Gray, I think I know my Bible, and I don't find any such verse in it.

D. — Yes, your reverence, that is just the charm. *It's in the Bible* but *you can't find it!*"

He also gives the following popular recipe for the whooping cough: —

"I know," said one of my parishioners, "what would cure him; but m'appen you wouldent believe me." "What is it, Mary?" I asked. "Why, I did everything that everybody teld me. One teld me to get him breathed on by a pie-bald horse. I took him ever such a way, to a horse at ———, and put him under the horse's mouth; but he was no better. Then I was teld to drag him backward through a bramble-bush. I did so; but this didn't cure him. Last of all, I was teld to give him nine fried mice, fasting, in a morning, in this way: three the first morning; then wait three mornings, and then give him three more; wait three mornings, and then give him three more. When he had eaten these nine fried mice, he became quite well. This would be sure to cure your child, sir."

TO MAKE SUGAR-COATED PILLS.

The *Druggists' Circular* gives the following method of imitating the sugar-coated pills that are made on a large scale: "Take the white of an egg, and in an evaporating dish beat with it as much powdered sugar, passed through a very fine sieve, as will make rather a thick fluid. Then place it in a water-bath and evaporate to dryness, stirring constantly, that no sugar may be deposited. Pulverize and set aside for further use, marking it "Albumen c. Saccharo," or similarly. When pills are to be coated, they first must be rolled (in a mortar) in an ethereal solution of balsam of tolu, in order to prevent the coloring of the sugar; and besides this, the coating will dry more rapidly, the pills become firmer, not being able to absorb the water (moisture) of the "paste." From the mortar the pills are transferred to a sheet of writing-paper, with the sides bent upwards, shaking being continued till they are perfectly dry. Then to a small quantity of the saccharated albumen add a few drops of water, at the same time beating for a short while, so that a thick paste will be formed. Into this mass the pills are stirred, and, when moistened on all sides, quickly poured into a wooden pill-box, which has been previously filled about one third with the finest powdered sugar obtainable, and immediately shaken, or rather rolled, in a lively way and with great force, separating from time to time those cohering. When no more sugar will adhere, they are dried over a gentle fire, taking care not to bring them too near the stove, lest they should crack. Shaking, of course, must be continued till dryness is effected. If necessary, the sugar coating is repeated. No tin box must be employed, for then the pills will be turned black. Glass is too smooth."

"MIXED CHOCOLATES." — A colored *brother* called at a drug-store saying, "Missus wants two ounces mixed chocolates." The druggist asked if he was sure "missus" said mixed chocolates. "Yes, sah — sure, the baby is sick, and she wants two ounces mixed chocolates." The medicine man resorted to the usual oracle provided for such occasions, namely: "What sounds most like it?" — "Ah, your missus sent you for chalk mixture, did she?" "Ye — yes, sah — dat's so."

POISONOUS EFFECTS OF ORANGE-PEEL.

Dr. GIBBONS writes as follows to the *Pacific Medical and Surgical Journal*: "Many years ago we had in charge two little girls, sisters, four and six years of age, who were seized with violent inflammation of the bowels from swallowing the rind of the orange. One of them died in convulsions, and the other had a narrow escape. Since that time quite a number of instances similar in character have come under our observation. Quite recently we have seen a child, something over a year old, that was attacked with violent dysenteric symptoms, for which no cause could be assigned. The symptoms were so identical with those which we had previously noticed to arise from poisoning by orange-peel that we were induced to inquire particularly if the child had an opportunity of getting this substance in its mouth. We were informed that it had been playing with an orange and nibbling at it just before the attack of disease. The discharges from the bowels were frequent and painful, and consisted of blood and mucus. After a week of severe enteric inflammation, the child died. We have no doubt that the disease was brought on by the rind of the orange. Though but a small quantity must have been swallowed, yet a very small quantity of such an indigestible and irritating substance will often produce the most serious consequences. The oil of the rind is highly acrid, and adds greatly to the noxious quality of the indigestible mass. We learn that it is a common practice among children at some of our public schools to eat the rind, and that juvenile merchants have been known to trade off the inside of the fruit for the skin."

POPULAR POMADES.

Cold Cream.

Spermaceti	$2\frac{1}{2}$ ounces.
White wax	1 ounce.
Oil of sweet almonds	10 ounces.

Melt over a water-bath, and pour into a mortar. Triturate and beat until a white cream free from grains is obtained, adding by degrees —

Triple rose-water	2 ounces.

Towards the end of the operation perfume with —

Oil of rose	10 drops.
Tincture of benzoin	5 "
" " ambergris	2 "

Beat again. The more it is beaten, the whiter and better it will be.

Pomade a la Sultane.

Spermaceti	2 ounces.
White wax	1 ounce.
Oil of almonds	4 ounces.
Rose-water	1 ounce.
Mecca Balsam	4 drachms.

Melt together over a water-bath the wax, spermaceti, and oil. Pour into a marble mortar, and beat until homogeneous. Lastly, add — beating all the time — the balsam and rose-water.

Pomade with Butter of Cacao.

Prepared grease	8 ounces.
Almond oil	5 "
Butter of cacao	10 "

Melt; pour into a mortar; triturate well, and perfume with essence of vanilla.

Pomade to Paste Wigs.

Isinglass	1 ounce.
Water	8 ounces.

Melt and add —

Alcohol	8 ounces.
Tincture of benzoin	3 "
Turpentine	2 "

Place over a water-bath, and mix.

Druggists' Circular.

MEDICAL MAGAZINES FOR OCTOBER.

The New York Medical Journal has original communications on Sympathetic Ophthalmia, by Dr. R. Pooley; Embolism in its Relation to Disease, by Dr. W. Coles; the Relations between Physicians and Apothecaries, and between these and their Respective Patients and Patrons, by Dr. J. H. H. Burge; the Influence of Excessive and Prolonged Muscular Exercise upon the Elimination of Effete Matters by the Kidneys, by Prof. A. Flint, Jr.; and on the Early Symptoms and Treatment of Pott's Disease of the Spine, by Dr. J. A. Wood.

The American Practitioner has leading articles on Pelvic Rachitis, by Dr. J. T. Whittaker; Hydrate of Chloral in Insanity, by Dr. J. Rodman; Malarial Fevers and their Treatment, by Dr. J. Hale; Immovable Apparatus in Diseases of the Knee-joint by Prof. R. O. Cowling; a Case of Cholera Infantum by Dr. B. M. Wible; and on a case of Ovariotomy by Prof. D. W. Yandell.

In the *Chicago Medical Journal*, Dr. I. N. Danforth discusses the Cell Theories of Huxley and Virchow; Dr. A. R. Jackson, Non-Ovarian Menstruation; Dr. J. E. Thornburgh, Scorbutic Dysentary; Prof. D. T. Nelson, a Case of Fracture of the Spine; Dr. D. Greenberger, Teaching the Deaf and Dumb to Speak; and Dr. J. E. Harvey, Cerebro-Spinal Meningitis.

Most of our medical exchanges for the month fail to reach us before we go to press.

NÉLATON. — A good anecdote is told of Nélaton. Going through one of the streets of Paris one day he came upon a crowd standing in front of a drug store. There a man lay stretched out who had been terribly wounded in the abdomen by a sharp buggy shaft, so that a large part of his intestines protruded. His life could be saved only by a very difficult and dangerous operation; but Nélaton was equal to the occasion; and soon his patient, quite a wealthy man, was sent home out of danger. For three weeks Nélaton heard nothing more of him; but then he made his appearance, and asked his preserver how much he owed him. "Hundred and fifty francs," replied the surgeon. "That is too much," said the man, "but give me a specified bill: here is your money." Nélaton sat down and wrote as follows: "For adjusting a metre and a half of the intestinal canal, at a hundred francs per metre, one hundred and fifty francs."

MEDICAL FEES IN PRUSSIA. — These are regulated by law on decidedly economical principles. For a first visit within the city limits, a physician is allowed to charge from 50 cents to \$1; for each subsequent visit, 25 to 50 cents; if at a distance of from one to five miles from town and suburbs, his first visit may be from 75 cents to \$1.50, and subsequent ones from 50 to 75 cents. For a first visit at night he gets, if it be in town, from \$1.50 to \$2.25; if more than a mile out of town, from \$2.25 to \$3; following night visits being, in town from 75 cents to \$1.50, in the country from \$1.12 to \$2.25. He may not charge for more than two visits a day, unless they be made by special request, nor must his fees for all attendance on any one patient within twenty-four hours, exceed \$2.25.

THE BONES OF LUNATICS. — According to a paper presented to the Pathological Society by Dr. Dickson, paralytic lunatics have always soft and brittle bones. This fact will be useful to the keepers, who will, in future, know how to explain any half-a-dozen broken ribs or so. We really think that Dr. Dickson should have waited for further researches into the subject before publishing so startling, and, for unhappy lunatics, so dangerous a generalization.

Boston Journal of Chemistry.

VOLUME V. BOSTON, JANUARY, 1871. NUMBER 7.

Familiar Science.

SPONTANEOUS COMBUSTION.

INSTANCES of spontaneous combustion are so common now-a-days that we cannot help thinking that people are becoming more careless than they used to be, or else they are ignorant of the nature and the causes of this kind of combustion. The latter, we doubt not, is more frequently the case, and this is our reason for taking up the subject here.

Our readers are aware that ordinary burning is nothing but rapid *oxidation*, or the union of the combustible substance with the oxygen of the air. But they may not all be equally familiar with the philosophy of *slow* combustion, which is a more gradual oxidation of a substance. The *decay* of animal and vegetable substances is a process of this sort. When a log of wood rots in the forest, it is as really burned up as when it blazes on the hearth of an old-fashioned fireplace. The carbon and hydrogen which make up the greater part of its bulk are oxidized in the former case, as in the latter, and the products of the combustion — carbonic acid and water — are the same. And it has been proved that the *heat* generated in both forms of burning is precisely the same; the only difference being, that in ordinary burning it is all set free in a short time, while in decay it is developed so slowly that we do not perceive it.

The *rusting* of metals is another instance of this slow combustion, the *rust* being the metal after it is burnt, or oxidized. Heat is generated in this process, as in that of decay; and if the rusting can be made sufficiently rapid (as when a large pile of iron filings is moistened and exposed to the air), the rise of temperature is readily detected. A remarkable case of heat developed in this way occurred in England during the manufacture of a submarine cable, and is described in Rolfe and Gillet's "Natural Philosophy:" —

"The copper wire of the cable was covered with gutta-percha, tar, and hemp, and the whole inclosed in a casing of iron wire. The cable, as it was finished, was coiled in tanks filled with water: these tanks leaked, and the water was therefore drawn off, leaving about 163 nautical miles of cable coiled in a mass 30 feet in diameter (with a space in the centre 6 feet in diameter) and 8 feet high. It rusted so rapidly that the temperature in the centre of the coil rose in four days from 66° to 79°, though the temperature of the air did not rise above 66° during the period, and was as low as 59° part of the time. The mass would have become even hotter, had it not been cooled by pouring on water."

In this case the heat set free caused the oxidation to go on faster and faster; and this is what occurs in spontaneous combustion, which is simply "rapid combustion developed gradually from slow combustion." There is no more common source of such combustion than the oily rags used by painters in their work, or the cotton waste used for wiping machinery. When such substances have become saturated with oil, if they happen to be thrown into a heap, the oil begins to oxidize slowly; but the heat produced makes the oxidation more and more rapid until the mass bursts into a flame. Oils that oxidize readily, like cotton-seed oil, are especially liable to take fire. Oil spilt on dry sawdust has been known to ignite in the same way.

It sometimes happens that hay, cotton, and many forms of *woody fibre*, — as tow, flax, hemp, rags, leaves, spent tan, straw in manure heaps, etc., — when stacked in large quantities in a damp state, take fire spontaneously. Here the oxidation is merely that of incipient decay or fermentation, which is promoted by the dampness. The confined heat accumulates, as in the case of the oily rags or cotton, until it is sufficient to cause rapid combustion. According to M. Chevallier and others, pulverized charcoal, prepared for making gunpowder and stored in heaps, has been known to ignite, when neither oily nor damp; the very slow action of the oxygen of the air upon the charcoal itself being gradually accelerated by the heat produced until it set it on fire.

Whether grain or seeds of any kind be liable to spontaneous combustion is doubtful; though several French savants came to the conclusion that a barn had caught fire from the spontaneous ignition of damp oats stored in it. But however that may be, it will be evident from the facts we have given that many fires, involving great destruction of property, have been the result of spontaneous combustion; and it is probable that many conflagrations ascribed to incendiarism have really owed their origin to the same cause.

THE AURORA.

THE brilliant auroral displays of the present season have attracted great attention on both sides of the Atlantic, and we have received several letters from patrons of the JOURNAL, asking us to take up the subject in one of our articles on "familiar science." We will therefore attempt to state as briefly and simply as possible the main facts known about the aurora, and also the most plausible theory of its nature and origin.

We will not dwell upon the various appearances which the aurora assumes. These are familiar to our readers, and besides they are so varied that space would fail us for describing them. And what description could do justice to their wonderful beauty and splendor? Even the poet's pen, dipped in the colors of the rainbow, could not transfer to paper the flashing glories that light up the whole canopy of heaven in the grander displays of the aurora; much less could plain prose hope to portray them adequately.

We may remark, however, that the most common form of the aurora is a pale diffused light near the horizon, like the first glimmering of the dawn; and hence its name, from *Aurora*, the Roman goddess of morning. In the northern hemisphere it is known as the *aurora borealis*, or "northern morning." Tennyson several times speaks of it by this simple Saxon translation of the Latin name; as in "The Talking Oak," —

> "The northern morning o'er thee shoot
> High up in silver spikes!" —

and in "Morte d'Arthur," where the gleam of Arthur's sword Excalibur is compared to "a streamer of the northern morn." The phenomenon as seen in the southern hemisphere is sometimes called *aurora australis*, or "southern morning." In its complete form it consists of a dark bank, or segment of a circle, of a hazy or slaty appearance, surmounted by an arch of light, from which luminous streamers quiver and flash upwards. These sometimes appear to unite near the zenith, forming what is called a *corona;* and sometimes several auroral arches are seen at once.

The distribution of auroras over the surface of the earth is very unequal. At Havana, but six have been recorded within a hundred years. As we travel northwards from Cuba, they increase in frequency and brilliancy; they rise higher in the heavens, and oftener reach the zenith. If our journey northward lies along the meridian of Washington, we find, on an average, near the parallel of 40°, only ten auroras annually. Near the parallel of 42°, the average number is twenty a year; near 45°, it is forty; and, near 50°, it is eighty. Between this point and the parallel of 62°, auroras are seen almost every night, high in the heavens, and as often to the south as the north. Farther north, they are seldom seen except in the south, and from this point they diminish in numbers and in brightness as we approach the pole. If we make a like comparison for the meridian of St. Petersburg, we shall find a similar result, except that the auroral region lies farther to the north than in America. In the same latitude, we have more auroras in this country than are seen in Europe.

It will be observed that the popular notion that auroras are most frequent in the extreme polar regions is erroneous. In latitude 78° the average number is but ten a year; and at the north pole they are probably as rare as at the equator.

Auroras are sometimes of vast extent, being seen at the same time in both hemispheres. That of August 28th, 1859, was visible from California eastward to Russia, and from Jamaica northward to an unknown distance in British America; and that of September 2d, of the same year, was seen at the Sandwich Islands, throughout North America and Europe, and in those parts of Northern Asia where the sky was clear;

and there were auroras at the same time in South America and Australia. The auroral displays of the past autumn appear to have been of almost equal extent.

The *height* of the aurora above the earth has been quite accurately determined by observing its elevation above the horizon from several different places. From a large number of such observations, it is concluded that the height is seldom less than 45 miles, and that it is often as great as 500 miles. Some persons have believed that they saw auroras at a height of less than one mile, or below the clouds; but it is probable that the clouds were very thin, and that the auroral light was seen shining *through* them.

Many people have imagined that the aurora is sometimes attended with a peculiar rustling or crackling *sound;* but there is no satisfactory evidence that this ever occurs. The sounds in question have probably been due to the wind, the cracking of ice and snow, or other causes independent of the aurora.

Auroras are not equally frequent at all hours of the night, or at all seasons of the year. In our latitude they increase regularly in number from sunset till about midnight, and then diminish regularly till morning. In Canada the maximum is at 11 o'clock; farther north, at midnight; and still farther north, in Arctic regions, an hour later. In this part of the world they are more abundant in summer and autumn than in winter and spring.

The number seen in different *years* is also variable. A period of about sixty years from one maximum to another has been made out with tolerable certainty, with a subordinate period of about ten years; that is, there is a maximum every ten years, and a more remarkable maximum every sixty years.

The aurora is in all probability an *electrical* phenomenon. We will state very concisely the chief reasons for this theory of its origin.

The effects of the aurora upon telegraph wires are identical with those of an electric current. *Sparks* can be drawn from the wires during the auroral display, and *heat* is also generated. The characteristic *shock* caused by electricity can likewise be obtained from the wire; and *magnetism* is developed, — in some cases so abundantly that telegraphic signals can be sent without the aid of a battery. The magnetic needle is also affected by the aurora precisely as by an electric current; and *chemical decomposition* has been accomplished by its agency. The luminous phenomena of the aurora, with their varied colors, quiverings, and flashings, may be readily imitated by sending an electric charge through glass vessels containing rarefied air.

There is found to be a remarkable coincidence between the periodicity of the aurora and that of the *variation of the magnetic needle;* and the maxima of these periods coincide, moreover, with that of *the sun's spots.* These three sets of phenomena appear, therefore, to be connected in some way which scientific men do not yet fully understand.

Some of the recent auroras have been examined with the spectroscope. The spectrum of the light is not continuous, but is made up of several lines, among which are a red and a green one that may be due to hydrogen; but further observations will be necessary to settle the question.

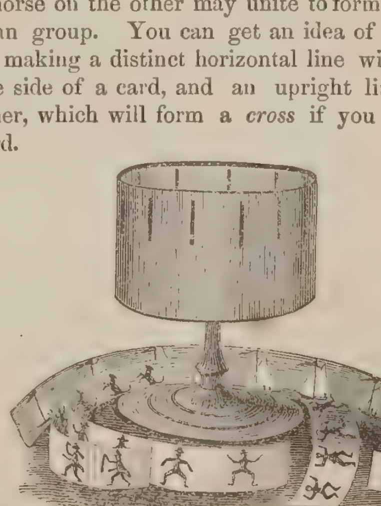
PERSISTENCE OF VISION.

In our November number, we referred to certain "curiosities of vision," but we by no means exhausted the subject. Some of the most singular optical illusions are the result of what is called "persistence of vision," and this we will make our theme to-day.

There are many paradoxes in science, and one of them is, that we see things after they are out of sight; or, to state it in a less familiar way, the impression made by light on the retina of the eye does not cease when the light is removed, but continues for about the eighth of a second afterwards. That is a very brief time, to be sure, but it is long enough to give rise to many peculiar effects. We all know that if a stick with a spark of fire on the end of it be whirled round rapidly, we see a circle of light. The end of the stick appears to be at every point of the circle at once, which of course it cannot be. "Seeing is believing," we say; but in this case, as in many others, the ancient "saw" fails us. The luminous impressions made by the spark at different points succeed one another so rapidly that they appear continuous.

We know also that when a wheel is turning very fast, we cannot distinguish the spokes. In this instance the successive impressions, being made on the same part of the retina, obliterate one another, so that instead of seeing *more* than actually exists (as with the lighted stick), we see *less* than we are looking at. It will seem to be another paradox when we assert that if we could look at the whirling wheel for only the thousandth part of a second instead of a whole second or more, we should see every spoke as distinctly as if the wheel were at rest; but we shall prove this before we get through.

Many optical toys have been made which depend upon this law of vision. The *thaumatrope* is one of the simplest of them. Two pictures are put on the opposite sides of a circular piece of card, which is twirled rapidly by means of strings fastened to opposite points of its edge. The two images combine in the eye, and we see one picture made up of the two. A bird may be put on one side of the card, and a cage on the other, and we see the bird in the cage when the card is twirled. So a man on one side and a horse on the other may unite to form an equestrian group. You can get an idea of the effect by making a distinct horizontal line with ink on one side of a card, and an upright line on the other, which will form a *cross* if you twirl the card.



The *zoetrope,** of which we give a figure, is another ingenious and amusing contrivance, the effects of which are due to the same cause. It is a cylindrical box, open at the top, turning upon an upright axis. Around the upper part of the box is a row of vertical slits. The successive positions which a moving body assumes are represented in order upon a strip of paper; and this paper is put within the box, which is then whirled rapidly. If we look through the slits, the pictures come before the eye one after another, and the impression of each lasts till the next arrives, so that they all blend together, and the object appears to be actually going through the motions depicted.

* This is a foreign invention, but a very neat form of it is made in this country by Messrs. Milton Bradley & Co., of Springfield, Mass.

The *intermittent* view of the pictures which is got by looking through the narrow slits is essential to the effect. If we look in at the top of the box, so as to see the pictures all at once as they are turned round, they will blend undistinguishably, like the spokes of the wheel in rapid rotation. The slits, by interrupting the view, limit the *time* that each is visible, and allow an interval for the perception of one impression before another is made upon the retina. The adjustment of the number and breadth of the slits, so that the successive impressions may blend in such a way that the motion may appear natural and at the same time be clearly seen, is a matter of considerable nicety.

There are many other curious things about the zoetrope, but we must not dwell upon the instrument longer; nor can we refer to other forms of it, some of which have attracted much attention from scientific men, especially Faraday, who has given the results of his investigations in the "Memoir on Optical Deceptions," in his *Experimental Researches in Chemistry and Physics.*

We have said above that if our view of a swiftly rotating wheel could be limited to a very small fraction of a second, we should see it as distinctly as if it were motionless. We can accomplish this by lighting up the wheel by an electric spark in a dark room. Wheatstone has proved that the duration of the spark is not more than $\frac{1}{24000}$ of a second; and viewed under this brief illumination, a wheel rotating at the rate of a hundred times in a second appears to be absolutely at rest. A single picture of it is formed in the eye, and the light is gone before a second impression can be made upon the retina. For the same reason, objects made visible by a flash of lightning appear stationary, no matter how fast they may be moving.

The fact that we do not cease to see objects while *winking* is of course explained by this principle of persistence of vision. The eyes are closed for less than the eighth of a second, and the impression upon the retina is renewed before it has time to fade away.

THE CIRCULATION OF MATTER.

Everything around us is in a state of change. Spring and autumn present to us annually the life and the death of the year. Vegetable nature shoots and flowers and decays, while the fruit which it bears passes into animal life, again to return to its original dust, and again to pass, in endless alternation, into new forms of life and beauty. The oak and the nettle, the poison and its antidote, the lion and the ephemeral insect, the sovereign and the serf, consist of the same matter differently combined; and the atom which to-day forms a part of any of them may in a brief period be the constitu-

ent of another, or may by turns occupy an essential place in them all. Nor is this transference of matter limited to the existing cycle. An atom which lay at the bottom of the primeval ocean may now be borne on the pinion of the eagle, and that which lived and breathed in the earliest age may now be asleep among the ashes of our fathers.

This incessant transition of matter from one phase of existence to another was well described by Bryant as

> "the circle of eternal change
> Which is the life of nature;"

and by Longfellow, in his "Rain in Summer:"—

> "Thus the Seer,
> With vision clear,
> Sees forms appear and disappear,
> In the perpetual round of strange,
> Mysterious change
> From birth to death, from death to birth,
> From earth to heaven, from heaven to earth;
> Till glimpses more sublime
> Of things, unseen before,
> Unto his wondering eyes reveal
> The Universe as an immeasurable wheel
> Turning forevermore
> In the rapid and rushing river of Time."

STORING OXYGEN.

Among the conclusions in Dynamical Geology adopted by scientists, and the inferences fairly deducible from them, are:—

1. That the earth was formerly a heated mass of liquid matter, necessarily repelling all vital gases and moisture; and that only a crust of variable thickness, at best thirty to sixty miles, has become sufficiently cooled to receive them.

2. That one half the weight of this cooled crust is oxygen.

3. That no condition or relation of elements and forces can increase, reduce, or destroy matter.

From the premises the inquiry arises as to the mission and place of the vital elements, especially oxygen, during a process which has gradually stored away in the cooling rocks many thousand times as much of it as now remains in surface activity.

If the cooled crust is fifty miles in thickness over continental plains, undisturbed ocean beds, or tracts soonest relieved from heat, the weight of oxygen which has become fixed by storing away is over a hundred thousand pounds per square inch.

If the gas so absorbed attended the planet in the commencement of the process in a free state, its pressure must then have been distributed quite uniformly about it. But from solar influence, sphericity and rotation of the earth, and interior heat currents, the process of cooling and loading must have been locally helped or hindered by the apparent caprices and chances which usually attend atmospheric phenomena, so that the crust becomes twice as thick in some places as in others; and we infer that the plains receiving this weight in excess must by depression overweigh and balance up other regions which have been less loaded.

If, then, plains corresponding with the bed of the Northern Atlantic on the one hand, and the valley of the Mississippi on the other, receive different measures of oxygen, and both of them receive much more than does the strip of surface between them, we can infer that the very different measures of elevation of these three divisions of surface, as they appear to-day, result from the difference in the loading of ponderable gases. This difference may be 50,000 pounds per square inch, and the plains receiving such excess of weight, resting upon an elastic or liquid base, must become depressed, and portions between them — sutures to those armor-plates — are slowly forced up into mountain ranges, in direct compliance with the simplest law of nature, — gravitation.

If there was formerly a thousand times as much free oxygen about the earth as to-day, then there has been at succeeding periods every other lesser measure of it down to the present, during nearly all which reach of time the heat and density of the atmosphere were intolerant of air-breathing life. And the naturalist will choose his period in the latter part of that vast stretch of time for the introduction of the gigantic tree ferns, and other extravagant forms of vegetation. An intensely stimulated life is crowded upon every opportunity for it. Heat was then the chief hindrance to growth, and only mountain-tops and polar circles were first endurable.

Atmospheric pressure develops heat; so from the presence of oxygen we infer weight, pressure, force, — heat. Solar heat depends on atmospheric pressure. Mount Washington is sterile under the brightest July sun. No warmth is felt above the lowest mile of air, and a temperature of 100° prevails at the fiftieth mile above the surface.

Are we not asking too much of the sun in assuming solar heat to be positive? Has the "Newtonian law" received sufficient attention? Will not gravitation be yet credited as the force which develops the most mysterious and perplexing appearances? When the earth shall have absorbed the ponderable elements for which it has an affinity, and which press upon it with immense power, will it not have arrived at the condition of the moon? Is not absolute cold a profound rest of matter, — equilibrium?

W. D. H.

THE ALLIGATOR.

We take the following from an entertaining article on "Florida" in the December number of *Lippincott's Magazine*:—

"The female alligator will not allow the male to approach her nest. He has a gluttonous habit of eating all the eggs, thus necessitating her laying more, which she does not like to do. So, whenever she catches him in that neighborhood, she thrashes him on general principles, — he either has done mischief or intends it: at any rate, he is meddling in domestic matters, and deserves snubbing. I am told that it is really amusing to see the big bully stick his tail between his legs and sneak off, the very image of a hen-pecked husband, after one of these conjugal scoldings. He is not by any means a model husband; and although he takes his thrashing kindly, he revenges himself by watching until the eggs are really hatched, and then eats up as many of the causes of the family dispute as he can catch. Young alligators don't like to know their own fathers.

"I heard of but few instances where these creatures have attacked grown men: they are fond of children, and show their attachment to the offspring of other people as they do to their own. In one instance, where a man on horseback was crossing a ford, he was seized by the leg; but when his dog plunged in, the alligator left his leg to take the more delicate morsel. In another instance, an alligator struck at a mule pulling a cart, and bit out two spokes from one of the wheels, leaving a tooth sticking in one as a memento of the visit. He hurried off with great speed, on the lookout, I suppose, for a dentist.

"'Gators like dogs, pigs, and young darkies. The dog is a special favorite. The whine of an alligator is easily mistaken for that of a puppy, and may mislead a young and inexperienced dog. A wise Florida dog will not go boldly down to the water to drink; he learns by experience after having been eaten once or twice. If the shore is open, he will draw all the alligators to one place by barking, and then scamper off to some other place where the coast is clear; or he will creep down to a moist spot, tail down, body crouched, eyes skinned and ears up, pushing his paws before him slowly to feel the water, lapping it without noise, and then sneaking away again.

"The alligator has his uses: near every house you find more or less swamp, and in every swamp more or less alligator. I heard one lady complain very much because some traveller had killed her alligator. He lived near, and killed snakes, frogs, young wild-cats, and other varmints: thus he earned his board, and was consequently protected; besides this, he was useful in preventing young children from straying too far from home."

USEFUL RECIPES.

Indelible Blue Ink. — Dissolve five parts of oxide of molybdenum in the smallest necessary quantity of muriatic acid; also dissolve two parts of extract of liquorice, and six of gum arabic, in two hundred parts of water. Mix the solutions, and write with them on the linen to be marked. After writing, moisten with a solution of chloride of tin in water. This is an ink not only indelible in ordinary washing, but in acids and alkalies. It cannot possibly be removed, except by destroying the article written upon. In fact, it is an utterly indelible blue dye, while the black so-called indelible inks may be removed by cyanide of potassium.

Common Writing Ink. — The *Technologist* says: "In the recipes generally given for making ink, it is recommended to *boil* the ingredients. This is a very serious mistake. It should always be made with cold water. By this latter process, more time is of course necessary to make it; but then the ink is very superior, and entirely free from extractive matter which has no inky quality, and which only tends to clog the pen and to turn the ink ropy and mouldy. Take gall-nuts, broken, one pound; sulphate of iron, half a pound; gum acacia and sugar-candy, of each a quarter of a pound; water, three quarts. Place the whole of these ingredients in a vessel where they can be agitated once a day; after standing for a fortnight or three weeks, the ink is ready for use. Logwood and similar materials are often advised to be used in conjunction with the gall-nuts; but they serve no good purpose, unless it be to make a cheaper article, which fades rapidly."

The following recipe is recommended for indorsing ink, black or colored: To make one pound, take balsam of copaiba, nine ounces; lamp-black, three ounces; indigo and Prussian blue, of each one ounce and a half; Indian red, three quarters of an ounce, and dry yellow soap, three ounces; grind all these ingredients on a slab to an impalpable smoothness, and the ink is then fit for use. The colors may be varied for different inks, such as chrome yellow and indigo for green ink; carmine and Indian red for red ink; vermilion, verdigris, etc. For such, the lamp-black and other colorings are to be left out of the recipe, but the other ingredients remain the same.

To Soften Kid Boots. — Melt a quarter of a pound of tallow, then pour it into a jar, and add to it the same weight of olive oil, stir, and let it stand till cold; apply a small quantity occasionally with a piece of flannel. Should the boots be very dirty, cleanse with warm water. It will soften any leather.

Bronzing for Leather. — A small amount of so-called insoluble aniline violet is dissolved in a little water, and the solution is brushed over the articles; it will dry quickly, and perhaps may have to be repeated. Shoes that are treated in this way present a beautiful bronze color.

Varnish for Oil Paintings. — Dextrine 2 parts, alcohol 1 part, water 6 parts. Varnish for drawings and lithographs: Dextrine 4 parts, alcohol 1 part, water 4 parts. These should be prepared previously with two or three coats of thin starch or rice boiled and strained through a cloth.

To make a new rope as limber and soft as an old one, boil it two hours in water, and then thoroughly dry it in a warm room.

The Arts.

MEMORANDA IN THE ARTS.

CARTRIDGES. — Gunpowder was at first always placed in the guns loose, by means of long ladles; and, in spite of the inconvenience and danger of the practice, it was three hundred years before any attempt was made to place it in cartridges. These were at first used only when rapid firing was necessary; and their employment did not become general, owing to the danger in serving the guns with them. Being made of parchment, paper, canvas, or linen, they were more or less incombustible, and left burning fragments in the bore, which had to be carefully removed before a fresh charge was put in. The vents of the gun were frequently choked, and the pieces rendered unserviceable, by fragments of the cartridge-bag forced into them. It was not till 1778 that Sir Charles Douglas suggested serge as a proper material for cartridges; and when his proposals were not treated with the attention they merited, he placed the whole ammunition of his ship in proper cartridges at his own expense. The advantages of serge as a material for cartridges, on account of its total consumption by the flame of the powder, are so great that its use soon become universal.

HYDROSTATIC WEIGHING MACHINE. — The London *Engineer* describes a new weighing apparatus invented by a Mr. Duckham. The principle consists simply in filling a cylinder open at the top with water, or oil by preference, and suspending the machine to a crane. A piston passes downwards through the cylinder and terminates in an eye, to which the articles to be weighed are attached. The machine is connected with a dial gauge, the indicator of which is worked by the liquid displaced from the weigher. On the load being removed, the liquid is returned to the cylinder. A peculiar merit of this machine is its lightness, a machine of 84 pounds' weight being equal to weighing ten tons. Others much lighter are capable of performing very delicate work, and others again can be made proportionately heavier which can weigh up to 100 tons. The machine has been tested in weighing the armor plates of the iron-clad turret ship *Abyssinia.* These are from eight inches to ten inches thick, weigh from seven to ten tons each, and are shipped and weighed by one process — lifted, slung, and weighed all at once.

FOOD FROM GUM TRAGACANTH. — A "Prepared Tragacanth" is put up in cans in Holland, and sold as an article of food. It is intended to answer the same purpose as arrow-root. Besides the pure tragacanth, it contains an aromatic gum and something resembling corn flour. Physicians speak well of it as food for invalids and infants "brought up by hand." We believe it is not yet introduced into the American market.

COLORED LINES IN STOCKINGS. — The reader has probably noticed that all good stockings are marked at the top with colored lines, the threads of which the lines are formed being dyed either blue or red. The dyes are not what are called "fast" colors, but are "fugitive." The lines are placed there by the manufacturer to show that the texture of the material of which the stockings were made was not injured when the articles were bleached by the action of chlorine. Although chlorine when carefully used, and when the goods are not exposed too long to its influence, is comparatively harmless, still, if employed in excess, it so destroys the texture of the stockings, that they quickly come into holes; hence the adoption of these colored lines, as before the chlorine can injure the material to this extent the red or blue color of these lines will be removed. Any stockings which do not show these colors are always sold at a lower price; but, for the reasons intimated above, they are dear at any price.

BOVINE, A NEW ARTICLE OF FOOD. — This article, prepared in Texas, is simply beef cut in steaks, including the fat, and desiccated in a current of pure heated air, and then subjected to a pressure of from 6,000 to 10,000 pounds to the square inch in cast-iron moulds, by which process it is made into a block or cake about twenty-five per cent. heavier than water. It is then slipped into a tin pan of the same size, and surrounded with melted suet or fat of the animal, and hermetically sealed. Thus dried, compressed, and excluded from the air, it will keep indefinitely, and the nutriment of a barrel of mess beef is furnished in less than one sixth the bulk and weight, and of a much better quality, as, not being salted, or only sufficiently to suit the taste (salt not being used as an antiseptic), it is free from the evils produced by salt meats, such as scurvy, etc.

WINDOWS FOR NARROW STREETS. — The London *Builder* recommends a plan for lighting a dark room, in which the darkness is caused by its being situated on a narrow street or lane. If the glass of a window in such a room is placed several inches within the outer face of the wall, as is the general custom in building houses, it will admit very little light, that which it gets being only the reflection from the walls of the opposite houses. If, however, all the panes of glass are roughly ground on the outside, and flush with the outer wall, the light from the whole of the visible sky and from the remotest parts of the opposite wall will be introduced into the apartment, reflected from the innumerable facets which the rough grinding of the glass produces. The whole window will appear as if the sky were beyond it, and from every point of this luminous surface light will radiate into all parts of the room.

PRINTING ON TIN. — This is a new process just patented in France. The preparation of the inks, or colors, which are used, is not made known. After the tin plate is printed, it can be made up into any desired shape, as the printed surface is not injured by moderate hammering, nor in the process of soldering. A great variety of canisters, boxes, etc., are already made of this material, and it is likely to come into universal use. The same French house has patented a method of lining tin canisters with a silicious material, which protects the metal from the action of the acids in pickles, preserves, etc. This also promises to be a valuable invention.

WATER-PROOF GLUE. — Immerse common glue in cold water until it becomes perfectly soft, but still retains its form; then put it into common raw linseed oil, and apply a gentle heat, until it is completely dissolved by the oil. It is then used like ordinary glue. It dries very soon, and water has no effect on it.

A glue which will resist water to a considerable degree is made by dissolving common glue in skimmed milk. Fine levigated chalk added to the common solution of glue in water constitutes an addition which strengthens it, and renders it suitable for sign-boards and other things which must stand the weather.

A glue that will hold against fire and water may be prepared by mixing a handful of quicklime with four ounces of linseed oil. Thoroughly levigate the mixture, boil it to a good thickness, and then spread it on thin plates in the shade; it will become exceedingly hard, but may be dissolved over a fire, like ordinary glue, and is then fit for use.

Where glue is to be exposed to the weather, common glue, protected by a good coat of oil color, is superior to the above. If both are combined (that is, the water-proof glue and the paint) a much greater advantage may be obtained.

NATHAN HALL, of Durham, New Hampshire, in 1833, thanked God that he "lived in a hilly country where it was impossible to build railroads." To-day the cars run through his door-yard and within a few feet of his house.

RAILROADS SIXTY YEARS AGO.

THE following letter, in reply to a suggestion concerning railroads, was written by Chancellor Livingston, who had been associated with his brother-in-law, Robert Fulton, in the application of steam to navigation: —

ALBANY, *March* 1, 1811.

DEAR SIR: I did not till yesterday receive yours of the 25th of February; where it has loitered on the road, I am at a loss to say. I had before read of your very ingenious proposition as to the railway communications. I fear, however, on mature reflection, that they will be liable to serious objection, and ultimately more expensive than a canal. They must be double, so as to prevent the danger of two such heavy bodies meeting. The walls on which they are placed must be at least four feet below the surface and three feet above, and must be clamped with iron, and even then would hardly sustain so heavy a weight as you propose moving at the rate of four miles an hour on wheels. As to wood, it would not last a week. They must be covered with iron, and that, too, very thick and strong. The means of stopping these heavy carriages without a great shock, and of preventing them from running on each other — for there would be many running on the road at once — would be very difficult. In cases of accidental stops, or necessary stops to take wood and water, etc., many accidents would happen. The carriage of condensing water would be very troublesome. Upon the whole, I fear the expense would be much greater than that of canals, without being so convenient. R. R. LIVINGSTON.

A CHROMATIC PRINTING PRESS. — At the late fair of the American Institute, a press was exhibited which, with a single impression, prints in three different colors, and works as rapidly as any platen press can print in single color. Each of the three equal parts into which the surface of the inking-cylinder is divided, is supplied with adjustable color-strips of various sizes, to correspond in width with any line or part of line of type, and each part is supplied with a color from one of the distributing rollers. Lines are struck on the surface of the cylinder, which are numbered to correspond with lines and numbers on the chase, so that it is easy for the pressman to set his sectors (color-strips) to correspond with the lines of the type which it is desired to print in colors. Within a minute the press may be changed from two or three colors to one, by throwing two polished shells, or half cylinders, over the color arrangements, enabling the pressman to use three times the amount of distribution and inking surface that he now has in any one-color job press.

PAPER BOXES. — The making of paper boxes has within the past thirty years become a very heavy business. In 1840 there were but five manufactories in the country, — three in New York, one in Boston, and one in Philadelphia, — and their united production amounted to $20,000 a year; while now there are single manufactories whose production is estimated only by millions. The straight-edged shoe-knife has given way to machinery which cuts, scores, and clips out the corners, leaving the board ready to be pasted into form. In New York one shop employs three hundred hands, consuming on the average, per day, one ton of straw board, six reams of white lining paper, and one ream of glazed paper, besides five barrels of paste and seventy-five pounds of glue, turning out 10,000,000 collar boxes and 500,000 other boxes per annum; and still the establishments increase at the rate of seventy-five per year.

GLAZING FOR LINEN. — Add a teaspoonful of salt and one of finely scraped white soap to a pint of starch.

Agriculture.

CARRYING SEED-CORN SOUTH.

In an instructive article under the heading, "Corn and Climate," published on page 563, current volume Country Gentleman, Mr. Levi Bartlett notices a variety of corn, "long and successfully grown on an island in Lake Winnipiseogee, yielding from 100 to 135 bushels of shelled corn per acre." Some of it was sent from Vermont to New Jersey. He continues: "The original was not a very large growing kind; but having been long grown successively, in New Jersey, it has become very large, like the Southern corn. Last winter a Mr. Haines, of New Jersey, sent me per mail a splendid ear of this corn, measuring fourteen inches in length, and kernels to match. Now, it is certain that this ear was a lineal descendant of the John Brown corn. I have this day interviewed it (August 12), and find many stalks nine feet high, much of it not yet spindled out, and none in silk. . . . I grew the Brown corn several years, and then it was a medium-sized variety of corn. But by long years of cultivation in New Jersey it has attained the growth of New Jersey corn; and now it and the Illinois corn are of very little worth for cultivation in this section; the corn will not ripen, and the forage is too coarse and large for cattle fodder."

Writing mainly for Southern readers, I remark that Winnipiseogee Lake is 472 feet above tide-water, and surrounded by high lands that aid in cooling the local climate. On an island in this lake our semi-tropical cereal for long and successive years yielded "from 100 to 135 bushels of shelled corn per acre." The Cotton States can send no corn North that will be likely to improve plants thus fruitful. Indeed, it is desirable in all parts of the continent to bring the planting and maturity of this crop as near together as possible, to escape blighting drouth. If the climate will ripen a second 90-day variety of corn, let us plant two crops in succession in a year. The second will give us five times more fodder (stalk and ear included) than all the blades we now pull from an acre.

By planting seed very impressible to the influence of heat and light, in our sunny clime, we can organize about twice the quantity of food for man and beast per acre in twelve consecutive months, that can be grown in the climate of New England, the fertility of the soil being the same. Corn that once required five months to reach full maturity in the climate at the mouth of the Mississippi, now ripens its seed in two months and a half on the Red River in the British Province, in 50° North latitude. This shows how far the vital element in this plant changes its most important functions to meet a change of condition. It by no means proves that solar heat for two and a half months in latitude 50° North is equal to that of five months in the sugar-cane climate of Louisiana, as some meteorologists would have us believe. If maize had not already been carried far north and acclimated there, it would pay to do so to make it more fruitful in seed, and less in wood and weed, in more southern latitudes. Corn carried 200 miles north of Knoxville, into the climate of Lexington, Ky., and planted in a calcareous soil similar to that in this State, appears to be more fruitful than here, after acclimation. So far as I can learn, nothing is gained anywhere by a northern movement in the first or second crop. We might as well carry southern Irish potatoes and apples north for seeding, as corn. But where wheat is harvested in May and early in June there is plenty of time to make a crop of northern corn on the same land in season to seed to wheat again in autumn, in all cotton districts. In our longer summers and higher mean temperature for the year, we have a powerful agricultural force; but in our native plants there is less suceptibility to its influence. Hence, European cereals and grasses and northern maize have advantages for southern farmers not found in any purely southern plants. Let us avail ourselves of all the physiological resources of northern latitudes, and unite them with all the climatic advantages that abound in our own land. — D. Lee, *in Country Gentleman.*

TO REJUVENATE PEACH-TREES.

The following is the substance of a communication made by Dr. George B. Wood to the American Philosophical Society, of which he is President: —

Peach-trees, after producing a few crops, not only cease bearing, but perish in a short time; whereas their natural life is fifty or sixty years, or more. The cause of this defective power of growth is owing to a deficiency of potash in the soil; and if this alkali be supplied to the tree, so that it shall reach the small roots and be absorbed, the fruit-bearing power is restored, and the fruit itself, prematurely perishing, is revived.

Believing at first with most persons, that the cause of decay lay in worms at the root of the peach-tree, Dr. Wood put in operation a plan which he had seen his father perform more than fifty years before, viz., of digging around the base of the stem a hole four or five inches deep, scraping away all the worms that could be found burrowing at the junction of the stem and root, and filling the hole thus made with wood-ashes from the fire, which of course retained all their potash. This was done in the autumn of 1868; and with a result in the following spring at which he himself was astonished. The trees appeared to have been restored to all their early vigor and freshness; they put forth bright green leaves, blossoming copiously, and bore a crop of fruit such as they had never borne before, many of the branches breaking down under the load of peaches.

Dr. Wood, in reflecting on these results, noticed that several of the peach-trees had no worms, and came to the conclusion that we must look for an explanation to some other cause than the destruction of a few worms; and this cause he believed to be the ashes, the potash of which, being dissolved by the rain, had descended along the roots to the rootlets, and presented to them the very food for the want of which they were dying. Decaying apple-trees, bearing stinted and inedible fruit, have been revived by a similar process, and with like results.

SAWDUST AS LITTER AND MANURE.

Persons who have tried sawdust for the purpose of keeping animals in the stable or pen clean, dry, and comfortable need not be told of its value for this purpose. It absorbs a large amount of liquid in proportion to its bulk, and is thus a convenient article for accomplishing the desired objects.

But the question of the value of sawdust as manure is a different one from its value as litter. We have seen land greatly benefited, and have seen land made worse by it. The result depends on two points, — the kind of sawdust, and the kind of land to which it is applied Many years ago, we saw a good garden made on a piece of raw, stiff clay, lying on a hillside. The clay was in a few years converted into a good, friable loam, chiefly by ploughing in and spading in large quantities of sawdust. The sawdust was made from oak, bass-wood, white-wood, etc.

On the other hand, we have seen a sandy loam rendered less productive by the application of pine, spruce, and hemlock sawdust. The resinous matter in such sawdust does not readily decompose, and observation teaches that it is not good for vegetation. The decay of branches, bark, and roots of these species of trees does not improve the fertility of soil.

Sawdust from most deciduous trees, when mixed with urine, soon takes on heat, which in a short time completely rots it, and the carbonaceous matter, having a great affinity for the ammonia evolved from the urine, prevents its escape. Resinous sawdust does not so readily rot, and hence has less power in saving ammonia. If such material is added to soil already too loose in texture, the effect is to increase that defect, while the resinous matter has absolutely a poisonous influence on the soil in reference to the support of crops. Hence it is at least doubtful whether pine and hemlock sawdust is good for any land, even when it has been used for bedding animals.

But in this vicinity what sawdust is made is from wood that contains none of the objectionable substance. Oak sawdust, it is true, is sometimes rather sour; but the alkaline quality of urine, in connection with the heat produced when the articles are mixed together, soon dissipates or destroys the acid. On tenacious soils the application of manure in which such sawdust is mixed cannot fail to be beneficial, and on none except those of too light a character would the effect be unfavorable. Perhaps no more ready means can be employed for saving the liquid portion of animal excrements — which some experiments show to be equal in value to the solid — than by the employment of sawdust as litter, and as an absorbent, whenever the article can be conveniently obtained. — *Lansing (Mich.) Republican.*

DETERIORATION OF WHEAT.

An intelligent writer in the *Mark Lane Express*, London, says, touching this subject: —

"So thoroughly illogical an article as is published in the *Prairie Farmer*, headed 'Why Wheat Deteriorates,' has rarely been seen in the columns of an agricultural paper; and we shall not do our practical readers the injustice of assuming that they need any help from us to discover the numerous fallacies it contains. Unfortunately, the article is read by many who are raw to their business, and therefore incapable of detecting any errors that would be palpable enough to an expert. In his heading, 'Why Wheat Deteriorates,' the author of the article has begged the question. He has started on the *assumption* that wheat *does* deteriorate, and directly proceeds still farther to *assume* that it has done so when the yield has declined from forty or fifty bushels per acre to ten bushels. Thus the writer has *assumed* that a small yield is evidence of a deterioration of the constitution of the wheat plant. There we meet him with a challenge to prove that any such deterioration has ever been known to exist. Until the writer has found a few wheat plants that have nearly lost the distinctive characteristics of wheat, and that exhibit unmistakable signs of returning to the wild state, let him not talk of deterioration. Wheat produced at the rate of six bushels per acre is likely to be even healthier and better seed than that which formed part of a crop of fifty bushels per acre. A dense wheat crop is not necessarily healthier than a thin one, but is, on the contrary, more likely to take the rust. Neither is the produce of a crop grown on rich land so well adapted for seed as that grown on land in fair, healthy condition. The old farmers of England never take seed from rich land to poor, but *vice versa.* The amount of yield per acre is sure to be less when seed grown on rich land is sown, and as surely an opposite result is obtained from an opposite course of practice. The fault in America is not in the seed, but in the practice, common also in this country, of exhausting the land by repeated cropping without returning any of the fertilizing elements which the crops take away. The seed is right, but the farming wrong. In saying this, we

do not mean to allege that all soil is capable of producing a healthy wheat plant, because experience has proved that some soils require an occasional change of seed, and none demand it more imperatively than those black soils that are so highly esteemed by the farmers of this country. In effecting any such changes it is desirable to bear in mind the British maxim, — 'Get your seed from poorer land than your own.'"

COAL-GAS AND THE ROOTS OF PLANTS.

A suit was brought by the city of Aix-la-Chapelle against the municipal gas company for damage done to the public trees by the leakage of gas from the street mains, and in the course of the trial the question arose as to which of the constituents of the gas was the most mischievous. The subject was referred to Professor Freytag, of Bonn, as an expert, and he at once made a series of experiments to decide the question. A system of lead tubes, perforated with small holes, was laid underneath a plot of ground, in which wheat, rye, rape-seed, and barley were growing; hydrogen, light carbureted hydrogen, and heavy carbureted hydrogen were uninterruptedly conducted through the pipes, under different parts of the beds, for six days, without perceptible effect upon the plants.

The same result was obtained when the city gas of Bonn, after being thoroughly purified, was passed through the tubes; but whenever the gas contained tarry matters, especially carbolic acid, the destructive action soon became apparent. The condensed particles of tar could easily be discovered in the earth and about the roots, which they coated and destroyed.

Prof. Freytag therefore came to the conclusion that the normal constituents of coal gas exercise no bad effects upon vegetation so long as air and oxygen can get access to the roots — that is, the various constituents of the gas have no worse effects than the nitrogen of the air; but, on the other hand, the tarry vapors, and especially carbolic acid, in consequence of their condensation and accumulation about the roots, are highly destructive to trees.

As it is nearly impossible to free the gas from these foreign vapors, it is safe to assume that it is destructive to trees, and ought not be conducted in pipes near their roots.

THE POTATO IN FRANCE.

The introduction of the potato into France has been ascribed to Parmentier, who is said to have found the plant in a field near Mayence at the time of the siege of that city about the middle of the last century. Whether this story is true or not, it is certain that, on his return from Germany to France, Parmentier used every means to encourage the use of the potato as food. He is said to have resorted to a curious stratagem to make it popular. Having planted a field of potatoes, he stationed around it a line of armed sentinels. This extraordinary precaution, of course, excited much comment, and the precious treasure, thus securely guarded, became very desirable to the neighbors. The vigilance of the guards was judiciously relaxed to such an extent that the crop was gathered by the more venturesome among the covetous neighbors, and thus the excellence of the potato became established in the vicinity. Parmentier next undertook to place the potato upon the tables of the rich. He presented himself before his king, Louis XVI., with a bouquet containing a flower of the *Solanum tuberosum* (potato); asked to describe the pretty flower, he spoke of the value of the tuber, and he induced the king to have it cultivated upon the royal grounds. In Germany the potato was known as a garden plant as early as 1710; it was not cultivated on the large scale till much later, and it required the famine of 1771–1772 to overcome all prejudices against this esculent. Even at the beginning of the present century, according to M. Pepin, very few varieties of potato were cultivated, and these chiefly for cattle; it was not used by the better classes until 1818 or 1820.

In the *Grand Encyclopedia*, commenced in 1750, it is stated, under the title *Potato*, that the peasantry of certain districts made use of it as an article of food, but that it is a crude element, difficult of digestion.

RULES TO MAKE A FARMER POOR.

1. Not taking a good agricultural paper.
2. Keeping no account of home operations. Paying no attention to the maxim: "A stitch in time saves nine," in regard to the sowing of grain and planting of seed at the proper season.
3. Leaving the reapers, ploughs, cultivators, etc., uncovered from the rain and heat of the sun. More money is lost in this way than most people are willing to believe.
4. Permitting broken implements to be scattered over the farm until they are irreparable. One of the Seven Wise Men of Greece said only this to prove his sense: "The time to mend the plough is when the plough breaks."
5. Attending auction sales and purchasing all kinds of trumpery, because in the words of the vender, the articles are "very cheap."
6. Allowing fences to remain unrepaired until strange cattle are found grazing in your fields and bruising the fruit-trees.
7. Planting fruit-trees with the expectation of having fruit, without giving the trees half the attention required to make them produce.

MISCELLANIES.

Hemlock Wood Proof against Rats. — A correspondent of the *Philadelphia Medical and Surgical Reporter* says: —

"Being surrounded by these animals, I found it necessary to keep fruits, butter, cheese, and other articles in boxes made of hemlock (*Abies Canadensis*). In these boxes I could keep the most toothsome delicacies in the cellar with impunity, even though the box afforded free ventilation, which, in many cases, is highly necessary.

"To test the matter still further, I made a box of dry hemlock boards, perforating each end of the box with a 7-8 inch circular hole. Into this box I put a large healthy rat, caught in a hemispherical wire trap, nailed it up securely, put it in a dark, quiet place, and awaited the result.

"On inspection, at the end of twenty-four hours, I found he had scarcely more than touched the wood. I returned the box, leaving the rat to his cogitations, which horn of the dilemma to choose.

"At the end of forty-eight hours, I made him another visit. He had evidently come to the conclusion that remaining inactive was to strand upon Scylla, while the effort to buy his liberty could do no worse than wreck him upon Charybdis. He had enlarged the hole sufficiently to get his head out, in which condition I found and dispatched him on the third morning of his incarceration."

Adulteration of Manures in England. — The subject of manure adulteration has attracted the attention of the Royal Agricultural Society of England, whose chemist, Dr. Voelcker, is now authorized to publish every month all analyses of adulterated foods and manures which pass through his hands. He has accordingly shown up several very glaring instances of worthless guanos and superphosphates, in which gypsum, earth, chalk, and sand figure in place of the genuine guano and bone-ash. One sample of bone manure contained only one per cent. of phosphate of lime and one per cent. of nitrogen; it was made up chiefly of gypsum and some cheap organic refuse, impregnated with sulphuric acid. It cost four and a half pounds sterling per ton, and was worth less than a pound and a half. Other specimens were still worse. This exposure is the more necessary now that the English farmer, as some one has said, "depends for success mainly on brains and bones, — his own brains, and somebody else's bones."

British Farm Statistics. — According to statistics recently published, there are 1,141,996 farm-horses at work in Great Britain. The aggregate of farm stock is decreasing. The reduction within a year amounts to 70,000 cattle, 350,000 pigs, and 1,100,000 sheep. 20,000 more acres are devoted to wheat, 84,000 to barley, 22,000 to oats, 14,000 to rye, 45,000 to beans, and 100,000 to peas, while of clover there are 365,000 acres *less* than there were the preceding year.

Virgin Soil in the South. — The South has an immense area of lands untouched by the plough, and destined hereafter to be the source of wealth and power, such as that section has never yet known. The extent of Government lands in acres in the Cotton States is put down as follows: Alabama still has 6,790,776; Mississippi, 4,828,069; Louisiana, 6,583,841; Arkansas, 11,574,430; Florida, 17,425,438; whilst Texas has over seventy millions belonging to herself. The homestead and preëmption laws of the United States afford an easy means to the immigrant of becoming at once a thrifty farmer in any of the States where the public lands are still unsold.

Hints about Flowers. — House plants ought to be stimulated gently once or twice a week. Rain-water, so refreshing to summer flowers, always contains ammonia, which also abounds in all liquid manures. If you take an ounce of pulverized carbonate of ammonia, dissolved in one gallon of water, it will make spring-water even more stimulating to your plants than rain-water. If you water your plants once in two weeks with guano water (one table-spoonful to a pail of water) they will grow more thrifty. Chicken manure dissolved in water is excellent.

Always keep the soil in your flower-pots loose. A common hair-pin used daily will stir the earth sufficiently.

Russian Apples. — The Commission of Agriculture at Washington has just received from the Imperial Botanical Gardens of St. Petersburg a collection of Russian apples, embracing specimens of about 400 varieties. These have arrived in perfect condition, and are well provided with grafts, which will be at once distributed to nurserymen and others who desire to experiment with them. It is believed that they will prove a valuable acquisition to the pomologists of our Northern and Northwestern States.

Climbing Plants. — According to M. Lévy, some species of climbing plants show a preference for particular trees, refusing to twine about some kinds, and clinging eagerly to others, to reach which they may have trailed for some distance along the ground.

Grape-leaf Pickles. — The Moravians in Salem, N. C., are said to put up cucumber pickles as follows: Put up a layer of the sour, wild grapes with the leaves of the vines in the bottom of the vessel, then a layer of the cucumbers, and alternate thus until the vessel is full, or until you have put in as many cucumbers as you desire. Then put in water enough to cover them, and place boards and weights on top to keep them under the water. They do not require any further attention, although you may, if you desire, take them out and finish them with vinegar

THE CATHEDRAL AT STRASBOURG.

THE siege of Strasbourg has drawn the eyes of the whole civilized world to "the old Alsatian city" and its magnificent Minster. The famous astronomical clock has also been an object of no small interest, and some of our Yankee newspapers have seemed to think that its fate was of more importance than that of the cathedral itself. But the clock is merely a gigantic toy, or at best a marvel of mechanical ingenuity. It is not the original mediæval horologe, as has been repeatedly stated in print, but, with the exception of a portion of the case, is wholly a work of the nineteenth century. It was begun by Schwilgue in 1838, and finished in 1842, and is far more wonderful in its way than its antique prototype. Even the moving images which amuse the looker-on when the hour is struck, especially at noonday, have been greatly improved by modern skill, and go through their various antics in a less jerky and stiff-jointed style than of yore. It would be tedious to tell all the manœuvres, whether chronological or comical, of this complicated time-keeper. It measures and marks periods from one second up to the slow cycle of the equinoctial precession, which takes over *twenty-five thousand years* for its completion. It has dials for all sorts of astronomical, civil, and ecclesiastical divisions of time; and it has processions of heathen deities, holy Apostles, and allegorical personages, — Youth, Manhood, Old Age, Death, and the like, — to say nothing of the cock that flaps his wings, ruffles up his neck, shakes his head, and wakes up the echoes of the church with his sonorous crow. But, after all, it is nothing more than a piece of cunning mechanism, and, being such, we need not wonder that it surpasses its predecessors of 1352 and 1547, — for the present is the third of these curious clocks. This is an age of machinery, as that was an age of art. It can build a better clock than was possible in the fourteenth century; but it cannot build a Gothic cathedral, — an achievement infinitely nobler. The clock is a machine; the cathedral is "a hymn to God sung in obedient stone."

This grand old Minster, like nearly all the European cathedrals, was never completed. According to the original plan, it was to have two spires of equal height; but only one was finished, and that not until more than four centuries after the edifice was begun. Indeed, the cathedral is an embodied history of Gothic architecture from its birth to its decline. The southern portal, in Byzantine style, dates back to the year 1002; the body of the church, to 1275; the façade and towers were begun in 1277, and the spire was finished in 1439.

If Longfellow's "Golden Legend" were as widely known as many of his poems, its references to Strasbourg cathedral would have gone the rounds of the papers ere this, but we have not seen the first hemistich of them in all that has been written on the subject. The opening scene of the poem is on (or around) the spire of the cathedral, where Lucifer is inciting the "powers of the air" to tear down

> "the ponderous
> Cross of iron, that to mock us
> Is uplifted high in air."

But the "Saints and Guardian Angels throng in legions to protect it," and the evil spirits are baffled. Neither can they

> "Seize the loud vociferous bells, and
> Clashing, clanging, to the pavement,
> Hurl them from their windy tower,"

for the bells have been baptized, as was the pious custom of that day, and can therefore defy the devil and all his imps. They cannot even break the windows, for the Archangel Michael flames from the painted panes. Then Lucifer says: —

> "Aim your lightnings
> At the oaken,
> Massive, iron-studded portals!"

But the Apostles and the Martyrs whose statues stand there as sentinels and warders repel the infernal invaders. Those same Apostles and Martyrs are still on guard to-day, but they would have been poor defenders against the thunderbolts of Prussian artillery, if the demon of war had tried to destroy the sacred structure. And yet were they not its defenders and saviours, after all? Was it not the German love and reverence for this ancient masterpiece of German art, with its myriad statues, its painted windows, its sculptured spire, its wealth of beauty and grandeur, its venerable and holy associations, that kept the cathedral almost scathless amid the storm of shot and shell that swept over the doomed city? Here is a finer theme for our poet than the mediæval superstitions wrought into this opening scene of the "Golden Legend!"

Farther on in the poem, Prince Henry and Elsie come to Strasbourg, and this is a part of their conversation in their first visit to the cathedral: —

> "*Elsie.* How very grand it is and wonderful!
> Never have I beheld a church so splendid!
> . . . . .
> Who built it?
> *Prince Henry.* A great master of his craft,
> Erwin von Steinbach; but not he alone,
> For many generations labored with him.
> Children that came to see these Saints in stone,
> As day by day out of the blocks they rose,
> Grew old and died, and still the work went on,
> And on, and on, and is not yet completed.
> The generation that succeeds our own
> Perhaps may finish it. The architect
> Built his great heart into these sculptured stones,
> And with him toiled his children, and their lives
> Were builded, with his own, into the walls,
> As offerings unto God. You see that statue
> Fixing its joyous, but deep-wrinkled eyes
> Upon the Pillar of the Angels yonder.
> That is the image of the master, carved
> By the fair hand of his own child, Sabina.
> *Elsie.* How beautiful is the column that he looks at!
> *Prince Henry.* That too she sculptured.
> At the base of it
> Stand the Evangelists; above their heads
> Four Angels blowing upon marble trumpets,
> And over them the blessed Christ, surrounded
> By his attendant ministers, upholding
> The instruments of his passion. . . .
> See, too, the Rose above the western portal,
> Resplendent with a thousand gorgeous colors,
> The perfect flower of Gothic loveliness!
> *Elsie.* And in the gallery the long line of statues,
> Christ with his twelve Apostles watching us!"

This is poetry, but it is a very photograph of the Minster as it now stands. We found it better than any guide-book description when we were there some two years ago. Erwin von Steinbach was the architect of the church from 1277 to his death in 1318, and his daughter and his son labored upon it for long years after; and to the three it owes the majestic façade, the sculptures of the south portal, and many other of its best features. "The Rose above the western portal" — a circular window more than fifty feet in diameter — is one of the most conspicuous ornaments of the façade; and seen from within, it is still "resplendent with a thousand gorgeous colors," as the poet has described it.

The spire is famous, not only for its exquisite workmanship, but as being the loftiest in the whole world; but just how high it *is* no two authorities agree in stating. Baedeker, who is usually trustworthy, makes it 524 English feet, but we think he is wrong. One of the best German works on architecture puts it at 442 feet (*German* feet, 34 of which are about equal to 35 English); and this is probably the truth, or near the truth.

ECHOES OF THE WAR.

SOMETHING approaching to regular postal communication with Paris is now established by a singular combination of ancient and modern methods. The outward service is by means of balloons; and the return mails are borne by carrier pigeons, which are brought from the besieged city by the balloons. But as the birds could not carry a heavy mail-bag, the aid of photography is called in to reduce printed and written matter to microscopic proportions. A large newspaper page is thus condensed into the space of an eighth of an inch. It is said that the Prussians are training hawks to intercept these feathered carriers; thus reviving the old art of falconry in opposition to that of sending messages by pigeons. And so, with balloons and photography on the one hand, and carrier pigeons and trained hawks on the other, we have the nineteenth century and the Middle Ages brought strangely together.

In our last, we gave some facts concerning food in Paris, gathered from the *Food Journal.* The December number of that magazine, just received, contains further reports on the same subject, "received by balloon post, Nov. 25th." Beef and mutton were then exceedingly scarce, and horse-meat was in great demand, as the next best thing to be had. The soup made from it is generally considered superior to that from beef,

and many prefer the meat itself to beef on account of its "game flavor." A well-known artist says: "I have taken to horse, not only by taste, but also as a hygienic measure; every day the beef is worse and worse; the cattle want exercise, and perhaps green fodder. As to horse, it is quite the contrary; we first ate the hacks, and now we have commenced on the fine animals. Good horse is undoubtedly better than middling beef." The price of the best equine "cuts" has gone up even to 5 francs (about a dollar) a pound. The flesh of the ass is also liked, and sells, "under the name of veal," for 4 francs a pound. Of other meat supplies the following extract will give an idea:—

"Cat is eaten and sold openly; and although I never had the pleasure of partaking of a *civet* of the kind — to my knowledge — I can assure you that cats are relished by a good many people, and are quoted at 6fr. each, while dog is quoted at 4fr. the half animal. I have, however, doubts about the dog. One journal declares that more than 24,000 cats have been sold and eaten. A student in medicine sent the following note to a friend: 'Come on Saturday to my rooms and eat a broiled cat, seasoned with pistachio nuts, olives, gherkins, and pimento, and washed down with Chablis. After dinner we will drink some Rhenish wine to the indivisibility of France.'"

The scarcity of more legitimate viands is shown by their prices, a few of which we will give in our currency. Ham is about $1.60 a pound; a goose brings $5; a pair of pigeons, $2.50; a turkey, $13; a rabbit, nearly $4; a dozen eggs, $1; a bunch of carrots, 50 cents; a pound of beans, $1. Choice preserved meats and delicacies of any kind command fabulous prices.

Not only is meat scarce, but the means of cooking it are becoming equally so:—

"Coal is always dear in Paris, and is now unattainable; and the charcoal is exhausted. There remains only wood; of this there is yet a good supply, and the price has only been slightly raised; it is now 60fr. the ton. Wood makes a very good fire, but not for roasting in the ordinary way; and we were reminded of this the other day, when we were to regale ourselves upon horse beef, by our cook saying, 'Madame, I have no coke left, so I have put the horse into the oven!'"

But, for all this, the Parisian must still have his joke. When dinner is ready, some one is sure to say, "To horse, ladies and gentlemen, — to horse!" Comical stories go the rounds; like that of the woman who is caught coming out of a house with something hid under her shawl; she is arrested, and a fine cat found upon her: "O! do not expose me," she cries, "it is for a poor sick friend!"

Scientific bodies are discussing matters of diet. Dr. Sée has given a lecture on the subject at the School of Medicine, and the main points of it have been printed and widely circulated. He says that the daily diet of an adult man may be made up of 100 grammes (a gramme is about $15\frac{1}{2}$ grains) of beef, 20 of salt fish, 750 of bread, 50 of bacon, and 50 of vegetables, — in all, 970 grammes, or a little less than two pounds of solid food, containing 88 grammes of albuminous matter; but as he loses daily 120 grammes of such matter, the deficiency of 32 grammes must be made up by auxiliary food or drink. Coffee and wine the Doctor specially commends, as diminishing the waste of the tissues; but he strongly opposes the use of spirits. "The abuse of these liquors," he says, "is the best accomplice of Prussia."

There are other things connected with the war of which we intended to speak; but the length of this article admonishes us to defer them to a future day.

THE STEAM-HEATING APPARATUS.

If we had anticipated exciting so much interest among our readers regarding the "model steam-heating apparatus" noticed in the last Journal, we should hardly have alluded to it. The amount of correspondence thus drawn forth from parties east, west, north, and south, is indeed burdensome, and it is quite impossible to reply by post. The apparatus was noticed as a novelty in mechanics, and as a matter of interest in connection with household economy. It was devised for our private use, and originated in a desire to meet a want which we had felt for many years. At the time the apparatus was constructed, we supplied it to about a dozen of our relatives and neighbors, and most of these, we think, are still in working condition. Some ten or twelve years ago, the patterns for the castings were burned in the great East Boston fire, which put end to further supplies. It is possible that we may be led to reproduce the various parts of the apparatus, and if so, a more detailed description of it, with cuts, will appear in the Journal.

THE METEOROLOGY OF NOVEMBER, 1870.

November has been as remarkable for its high temperature, and for the small amount of rain, as so many of the preceding months had been. According to Prof. Loomis's meteorological report, as given in the *College Courant*, the mean temperature for the month at New Haven was 43.3 degrees, or three degrees above the average temperature of this month. The highest temperature of this month was 62.7 degrees, on the 9th; the lowest was 26.1 degrees, on the 17th. The range of the thermometer for the month was 36.6 degrees, which is nine degrees less than the average range for this month at New Haven.

The mean temperature of the past eleven months has been more than two degrees above the average of the same months for the past ninety years; and the mean temperature of the past seven months has been three degrees above the average temperature of those months. So great a departure from the average temperature, continued for so long a period, has not occurred before for more than a century.

The amount of rain for November was 2.80 inches, which was nearly an inch less than the average fall for that month. The entire fall of rain for the last ten months has been nearly thirteen inches less than the average fall of that period.

The drought appears to have extended to the regular November shower of meteors. Prof. Newton reports that not more than 75 meteors were seen at New Haven on the mornings of the 13th and 14th, whereas 7,000 were seen two years ago. His conclusion is, that either the earth had not reached the margin of the great meteor stream by sunrise on the 14th, or else the stream itself, which for several years has been crossing the earth's orbit at a velocity of about 100,000 miles an hour, has all passed by, to return about the year 1900.

On the other hand, Prof. Rockwood, of Bowdoin College, says he saw enough meteors on the morning of the 14th to prove the return of the usual November shower, though the meteoric flights were at no time more frequent than one a minute.

☞ The subscriptions of some of our patrons expire with this number. We shall be happy to receive a remittance for another year, in token that they desire the paper continued.

THE DEATH OF GENERAL LEE.

Dr. R. L. Madison and H. T. Barton, attending physicians of General Lee, have contributed to the *Richmond and Louisville Medical Journal* a detailed account of his last sickness and the treatment pursued. They sum up the case as follows:—

"*Remarks.*—We had long been painfully impressed with the conviction that depressing moral causes were slowly but steadily undermining General Lee's health in a ratio far exceeding the inroads of mere physical disease. Indeed, how could it be otherwise? The terrible strain upon him during the momentous campaigns of 1863 and 1864, the agony of mind endured at Appomattox, the wail that went up from widows and orphans all over the desolated and ruined South, the bankrupt condition of his native State, the mute and eloquent woe appealing to him on all sides, were enough, and more than enough, to bow his mighty spirit, and to crush out, with fatal tread, the energies of his life! And more than this, with all this mighty sorrow weighing him down, he ever preserved a calm, serene, and even cheerful exterior. Few, even of his most intimate friends, knew the depths of his anguish, rendered all the keener, all the more poignant, by the very effort to repress it. He felt it his *duty* to conceal it, even while conscious that, like the Promethean vulture, it was tearing away his heart! No man less heroic than himself, no man less sustained by Christian faith and Christian principle, could have borne his burden for an hour. Yet, even with him, it was only a question of time. General Lee died of a broken heart, and its strings were snapped at Appomattox!

"In reference to the proximate cause of his death, we were of the opinion that it was due to passive congestion of the brain, not proceeding far enough to produce apoplexy or effusion. There was no positive evidence of acute softening, of cerebritis, or of embolism. There was no paralysis of motion or sensation, but marked debility from the first. His symptoms, in many respects, resembled concussion, without its attendant syncope. The treatment was based upon the above diagnosis."

EDITORIAL NOTES.

Velocity of Nerve Force. — Helmholtz has made some new measurements of the rate at which excitation is propagated along the motor nerves of man from the brain to the muscles. The ascertained velocity varies between 260 and 292 feet per second, and is also found to be greater in summer than in winter. This result led to a more exact observation of the influence of temperature, which is ascertained by the artificial cooling or warming of the arm. By this means the accelerating influence of a higher temperature has been clearly determined, so that the interval of time between an impulse of the voluntary power and the corresponding movement of the muscles is greater in winter than in summer.

Wooden Shoes. — The French and Germans out West continue to use wooden shoes, and a large establishment for their manufacture has recently been started in Iowa by a German. The cheaper kinds sell at from thirty-five to fifty cents a pair. These shoes are also much worn by dyers and other workmen whose employments expose the feet to the action of water and other substances injurious to leather.

The clattering of these wooden shoes on a pavement is a sound not readily to be forgotten. We remember well when it first startled our own ears. It was our first day on the Continent in the summer of 1868. We had come across from Dover to Ostend on a Saturday night, and taken an early train to the "quaint old Flemish city" of Bruges, where

we spent the Sabbath. Our hotel was close beside the venerable Church of St. James, and we had the windows of our room open to listen to the music of the mass. At length the service was over, and a thousand or more pairs of *sabots* came tramping out of the church. It was some moments before we could make out what the strange din might be, and then it seemed as comical as it had been frightful.

COFFEE LEAVES FOR MAKING TEA. — We remember the story of the Irishman, who, on being asked why he had stolen some coffee, replied, "An shure, to make *tay* of." If it had been the *leaves* of the coffee plant that Pat stole, this would have been no bull, after all. A Dr. Gardner of England has discovered that these leaves may be substituted for those of tea without any considerable loss of the peculiar properties belonging to the latter. In examining at a grocer's shop a great variety of teas, he noticed that one chest, labelled "Assam Tea," had a very peculiar appearance. On careful scrutiny he found it to be prepared coffee leaves. These were in small fragments, not rolled, being too harsh for that operation, and yielding a strong, pleasant infusion, acceptable to many on account of its comparative cheapness. The swindle was a more pardonable one than the ordinary sophistications of the Chinese herb. Indeed, if coffee leaves serve as a cheap *tea*, it would be a blessing to the poorer classes to have them generally introduced into the market instead of the "faced" and other adulterated forms of tea that are so common.

SPECIAL NOTICE TO OUR MEDICAL PATRONS. — By an arrangement with Messrs. Macmillan & Co., of London, we are enabled to offer *The Practitioner*, edited by Dr. Anstie, *and the* JOURNAL, at the very low price of *four dollars* per annum. This will be virtually furnishing this English medical monthly, the high character of which is too well known to need any endorsement from us, at the same price as is charged for the unauthorized American reprint issued in much inferior style. The regular price in this country for the English edition is five dollars. To those who subscribe through us it will be mailed from the publishers' branch house in New York, regularly and promptly on its arrival from London. We shall be surprised if very many of our friends do not take advantage of this liberal offer.

For other medical magazines sent in connection with the JOURNAL, see list in our advertising columns.

The price of the *Gynæcological Journal*, for 1871, is raised to *five dollars*.

LITERARY NOTES.

THE Harpers publish, just in time for the holidays, *The Adventures of a Young Naturalist* by Lucien Biart, and *My Apingi Kingdom, with Life in the Great Sahara*, etc., by Paul Du Chaillu, both of which we heartily commend to our young readers, or to their friends who are looking for Christmas gift-books for them.

Messrs. Scribner & Co. have issued three more volumes of their "Library of Wonders" — *Wonders of Bodily Strength and Skill*, by G. Depping; *Wonderful Balloon Ascents*, by F. Marion, and *The Bottom of the Sea*, by L. Sonrel — all excellent in their way. From the book on Balloons, we learn that these were first employed for military purposes in the wars of the French Republic in 1794, and some interesting facts connected with their use at that time are given by the author. The first Napoleon, however, did not favor them, and disbanded the companies of aeronauts that had been attached to the French army. It was not until our own recent war that they again played an important part in military operations. The war now going on in Europe is likely to furnish M. Marion with abundant material for an additional chapter to his entertaining book.

Messrs. A. S. Barnes & Co., of New York, publish, under the title of *The Metric System*, a sketch of the system and a Report upon it to the University Convocation of the State of New York, by Prof. Davies; together with John Quincy Adams's elaborate Report of 1821, and Sir John Herschel's Lecture on the subject in 1863. The publishers make it a volume of their "Teachers' Library," but it has an interest for the general reader as well.

Dr. Naphey's *Physical Life of Woman*, published by Geo. Maclean, Philadelphia, has reached its fiftieth thousand. It has been endorsed by the *Philadelphia Medical and Surgical Reporter*, the *Boston Medical and Surgical Journal*, the New York *Medical Gazette*, and other leading professional journals, as well as by Prof. W. A. Hammond, Pres. Hopkins of Williams College, and others. It is a less exceptionable work than most of its class; but we have our doubts whether the best book of the kind does not do more harm than good.

Land and Water, the English weekly commended in our last, is edited by Frank Buckland, well known as a naturalist and as an author.

By an arrangement with the publishers, we are enabled to furnish *The English Mechanic and World of Science*, together with the JOURNAL, at the very low price of $3.50 per annum; the former to be mailed weekly *post free*. We believe that the *Mechanic* alone has not heretofore been offered in this country for less than five dollars a year.

We can also furnish the *Building News*, published weekly in London, and the JOURNAL (the former post free), for $4.50, which is only *one half* the price ordinarily charged for the former on this side of the Atlantic.

The Academy, the admirable monthly review started by Murray a year ago, has passed into the hands of Messrs. Williams & Norgate, of London. It is still published at sixpence a number. Its scientific department, though but one sixth of the paper, is of itself worth more than that.

Nature, which has steadily improved from the start, has just commenced its third volume. It will be remembered that we furnish it with the JOURNAL for *five dollars*, and any one who makes the investment will find that he gets more than his money's worth before the year is out.

☞ WE learn from Messrs. Lebosquet Bros., of Haverhill, that they have placed in operation about one hundred of the new dust-and-gas-tight furnaces which we devised, and that every one is giving the highest satisfaction. The only reward we expect for our labors is in the feeling that we have contributed in no small degree to the comfort and health of so many of our patrons and friends in their happy homes. We predict that in ten years no other form of air furnace will be used by intelligent housekeepers in the country.

OUR MEDICAL EXCHANGES.

THE *New York Medical Journal* for December has the following Original Communications: I. E. S. Dunster, M. D. — The Relations of the Medical Profession to Modern Education. II. L. D. Mason, M. D. — The "Rubber Air-Cushion" in the Treatment of Complicated Fractures, and other Severe Injuries of the Lower Extremities, with Illustrative Cases. III. Frederick D. Lente, M. D. — Dangerous Effects of a Hypodermic Injection; Extraordinary Slowness of Respiration; Recovery. IV. E. Holden, M. D. — Relation of Hæmoptysis to Phthisis. V. J. H. Hobart Burge, M. D. — A Case of Partial Placenta Prævia. Novel Mode of controlling Hemorrhage. VI. P. De Marmon, M. D. — Report of Three Cases of Poisoning by Whiskey in Children, with Remarks on Alcoholism.

The *American Practitioner* has original articles on Non-malarial Origin of Fever, by S. Littell, M. D.; Carbonic Acid and Fever, by H. Beauchamp, M. D.; An Attempt to Designate and Identify the Cause of Several Diseases, by Duff Child, M. D.; A Musket-ball in the Frontal Sinus — Removal after Six Years, by Preston Peter, M. D.; Removal of a Pessary from the Bladder with Remarks, by Levin J. Woolen, M. D.; On the Treatment of Typhoid Fever, by J. Hale, M. D.; A Case of Chronic Spermatorrhea, by J. R. Barnett, M. D.

In the *Chicago Medical Journal*, the leading articles are as follows: I. Injury of the Head — Abscess, with Absence of Symptoms, etc., by C. T. Parkes, M. D.; II. A Case of Traumatic Tetanus, treated with Hyd. Chloral, by A. H. Kinnear, M. D.; III. Read to the Muskingum Co. Med. Society, by A. Ball, M. D.; IV. Clinical Experiences in Private Practice, etc. by Z. C. McElroy, M. D.; V. A Day amongst the Surgeons of Philadelphia, by John E. Owens, M. D.; VI. Prof. Beale and his Doctrines, by I. N. Danforth, M. D.; VII. Case of Irregular Innervation, by Walter Hay, M. D.; VIII. Cases from the Surgical Clinic of Prof. Moses Gunn, of Rush Medical College, reported by H. F. Chesbrough, M. D.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

ANSWERS to questions sent us will often be found elsewhere in the paper. Quite a number of our correspondents are referred to the article on the *Aurora* on page 73; others to "Useful Recipes," on page 75, and to items under "Arts" on page 76.

J. E., of HIGH GROVE, Ky., writes as follows: "You gave a rule in the JOURNAL for estimating the number of bushels in a bin or box. Another convenient one is as follows: Multiply the number of cubic feet in the box by the decimal .8, and the product will be bushels and tenths of bushels, very nearly. The decimal carrried out to five places is .80031."

QUERIST, from NEW YORK, wants to hear "what becomes of the water whirled down in the Maelstrom on the coast of Norway." It ought to be generally known, by this time, that this fearful whirlpool, as described in old books (and new ones not up with the times), is a myth. At certain stages of the tide there is something like a whirlpool, and in bad weather the place is a dangerous one, even for large vessels; but if these are wrecked, it is by being dashed against the rocks, or by foundering, — not by being drawn down into a vortex. See Lord Dufferin's "Letters from High Latitudes," Bayard Taylor's "Norway, etc.," and other recent books of travel. In 1859, an official report on the subject was made by Mr. Hagerup, Minister of the Norwegian Marine, who says that more violent currents of the kind are to be found at other points on the coast of Norway, but the worst of them is not so bad as the Maelstrom of the old stories.

A. V., BALTIMORE. See recipe for "Camphor Ice" on page 84.

W. R. Y., MILLERSBURG, Ohio. The following is a recipe for violet and other colored inks: Digest half an ounce of the proper aniline color in five ounces of alcohol, in a glass or enamelled iron vessel for three hours. Then add a full quart of ice or distilled water, and heat gently for several hours, until the odor of spirits has disappeared; then mix in two drachms of gum-arabic dissolved in half a pint of water, and allow the whole to settle. From the first experiment the exact proportions of color must be seen.

But, as we have said before, these inks are liable to fade, and cannot be commended. We heartily endorse the following from an exchange: —

"We deprecate, as wasteful of time, temper, and eye-sight, the fashion now prevalent of using violet and other tinted writing-inks. The chemist who will give to the world an ink *perfectly black in the act of writing*, and remaining so for all time, and of proper, but not a too watery fluidity, will confer a great benefit, and may make a fortune beside."

W. E. R. inquires why the sun and moon appear larger on the horizon than high in the heavens. The explanation generally accepted by scientific men is the fact that we judge of the distance of unknown objects (and consequently of their size) by comparing it with the distance of known objects. When the moon is on the horizon, we see that she is beyond all the objects on the earth in that direction, and therefore she seems farther off than when overhead, where there are no intervening objects to help us to judge of the distance.

J. R. H., ATHENS, Ala. We gave an account of the Metric system, with simple rules for reducing the denominations to English equivalents, on page 99 of our last volume (March, 1870).

A READER, commenting on our statement that the inventor of the lucifer match is not known, says that the person was a Mr. Walker, chemist, living at Stockton-on-Tees, England, and that he brought his invention before the public about forty years ago.

W. H. J., BOSTON, inquires for a simple way of coloring bee's-wax *red*, without injuring its properties.

J. G. P. asks why a wet rope contracts in length. Because the water, absorbed by capillary attraction into the fine tubes of the fibre, increases their diameter, and so diminishes their length.

JANE E. GILLIS, of RICHMOND, sent us $1.00 some time ago; but as she forgot to give the State, and as there are *twenty* post-offices of that name in the United States, we do not know where to send her paper.

A. R. TUCKER, of WOLCOTT, sends $1.00; but he fails to add his State, and there are five post-offices of that name.

Medicine.

HYDRATE OF CHLORAL.

Dr. J. P. Chesney, of New Market, Mo., communicates to the *N. Y. Medical Gazette* an account of his experience with hydrate of chloral, from which it appears that he has put in jeopardy the lives of several patients by using what is evidently a vile, impure compound. In describing what he has been using, he remarks as follows: —

"It looks like a translucent salt in a half deliquescent state — like a mass of clean snow saturated with clear water until it reaches the 'mushy' condition: and when taken up on the point of a clean knife-blade, leaves a greasy-looking moisture; it is perfectly soluble in a small quantity of water. The bottle containing it was two thirds full, and about half the size of an ordinary quinine jar, closed with a well-fitting glass stopper; label, in large blue capitals, 'HYDRATE OF CHLORAL.' No name of place nor of the manufacturer given. My druggist lives twenty miles distant, and I have had no chance to make inquiry as to its origin. Price $1 per oz. I have no doubt that the extensive demand for this article will cause our markets to be, for a time, flooded with worthless imitations, and the journals should warn the medical public of such a possibility, if not the probability."

Now, it is very strange that any physician should *risk* so much as to use a new and powerful agent which comes into his hands without assurance from any one that it is the article he wants. Upon the vial the name of maker was not given, and undoubtedly it was an impure, dangerous compound, bought by some druggist at a low price, and sent out to be dispensed to the sick and the suffering. Tens of thousands of ounces of *impure* hydrate of chloral are made and sold in this country every week, and no wonder physicians have such fearful experience with it. We have tested specimens of two lots of several thousand ounces each, which were loaded with impurities; and yet we have reason to believe that every ounce was placed in the market, and is probably now being dispensed by physicians. If physicians fully realized how they are deceived and cheated in this way, they would be more cautious, and thus save their own reputations and the lives of their patients.

THE PHYSICAL UNITIES OF THE HUMAN BODY:

DYNAMICAL, PHYSIOLOGICAL, PATHOLOGICAL, AND THERAPEUTICAL.

BY Z. C. M'ELROY, M. D., ZANESVILLE, OHIO.

If the human body were presented to a competent physicist for study, acquainted with the accumulated facts of its anatomy, physiology, pathology, dynamics, and therapeutics, unembarrassed by any previous theories, speculations, or conjectures concerning it, he would not consume much time in unveiling most of its hitherto impenetrable mysteries.

As the initial step, he would determine, as he could readily do, that it was composed of certain definite elementary bodies, common to earth, or inorganic nature, and in definite proportions; and controlled in all its processes of growth, repair, and decay, by the earth's forces, except in, as yet, one unexplained feature, to be noticed hereafter.

But little observation would satisfy him of the intimate relationship existing between it and all organic life on the globe, be it biped or quadruped, fish or fowl, worm or insect, in both material and force. Nor would he be long in determining that all animal life was but a higher type of the vegetable, seeing that directly, as in the herbivora, indirectly, as in the carnivora, or those subsisting on parts of both, the omnivora, they were all alternately dependent on the vegetable kingdom for food, from which to construct their tissues; and that there is, in certain vegetable products, material common to them all; so that at last the only real difference between them lies in their *forms*; and that in the scale of animal existences from the lowest, or most simple, to the highest, or most complex, each added function has behind it a special form of structure.

Nor would he fail to notice the almost continuous stream of material, solid, fluid, and gaseous, organic and inorganic, going from without into the interior of the body, as well as the equally continuous return current of matter, having undergone chemical changes in it, through the skin, from the lungs, and at stated intervals the contents of reservoirs of sewerage, — the bladder and lower bowel, — from the interior of each and all animal existences; the quantity being the chemical equivalents of the dynamic, or mechanical, chemical, thermal, sensory, emotional, intellectual, and psychological results, evolved in a given time.

Neither would he dwell long on the determination of the problem whether organic instrumentalities performed their functions at the expense of their substance, as the candle, or only furnished conditions for chemical changes in other matter, as the lamp. And his conclusion could hardly fail to be that they performed their functions at the expense of their substance.

No candle is designed or expected to be chemically changed at once, evolving all its light, heat, and other chemical products, as in the chemical changes occurring between the materials of gunpowder in the act of explosion; but for all the light and heat evolved, so much of its substance has been chemically changed into carbonic acid and aqueous vapor.

Entering upon the duty of grouping the separate viscera and tissues, no greater difficulties would be presented than those he had already overcome. It would be plain to him that provision must exist for the transformation of the food eaten into the forms and substance of the viscera and textures; and that from the means to these ends little or no sewerage would be necessary, after leaving the main alimentary tract; and consequently all so-called viscera, without conduits to the exterior, must of necessity act only in the interest of repair; and further that as each organic instrumentality performed its function at the expense of its substance, a general system of sewerage must exist to convey to the exterior waste or effete educts and material, much of which cannot be worked over again in the system, though some, as the alkalies, undoubtedly are, and perhaps others, as carbon and hydrogen. This is found in the system of so-called absorbents, while much effete gaseous matter finds exit at the lungs.

These things determined, as they all have been, and that beyond all cavil or doubt, the induction would necessarily follow that the leading processes of any animal body would be repair and waste, — histogenesis and hystolysis, — *i. e.*, constructive and destructive metamorphosis; and that so long as these processes proceeded normally, and molecular forms of structure normally reproduced, the result would be health, or ease of body; and that when disarranged, or molecular forms of structure lost, the opposite condition, or dis-ease, or want of ease, must necessarily result.

And from these premises the further induction would unavoidably result, that the physical and physiological unities of the human body are, —

1st, Material, *i. e.*, certain elements in definite proportions; 2d, Form, *i. e.*, that these elements must be worked into definite molecular forms of structure; 3d, Motion, *i, e.*, chemical changes, whose unit is motion, must occur in the molecular forms of structure, as fundamental conditions for the performance of normal functions.

Function is, then, demonstrated to be the expression, or so to speak, the language of the molecular forms of structure, and depends on the molecular forms of structure, and motion in the molecular forms of structure itself.

And these are the ideal unities into which merge all the accumulated facts of anatomy, physiology, pathology, therapeutics, and dynamics; and these ideal unities give rise to mental conceptions, which correctly represent the facts of organic life to the mind of each and every student of the human body, anatomically, physiologically, pathologically, therapeutically, and dynamically, which the separate facts themselves as certainly fail to do, disconnected from any ideal unities into which they can all be merged.

It is, then, apparent that there are not now, and never have been, and never are likely to be, any separate and specifically distinct pathological states or conditions in a human body; and, therefore, the long catalogue of what are now taught and believed to be separate and distinct so-called diseases must be materially abridged, if, indeed, the wet sponge is not necessary to erase them entirely. For, as they stand now, they certainly give rise to mental conceptions or ideals which do not represent the facts of life to any mind. A necessary condition for specifically different pathological states is human bodies specifically different in material, forms, and forces, which as certainly have no existence.

A physiological human body is made up of certain definite materials, with definite molecular forms of structure, and a definite velocity of motion, or chemical changes, in the molecular forms of structures. A human body in a pathological state can only consist of abnormal velocity of molecular changes, or changed or changing forms, one, or two, or all three. And into one or some combination of these ideal unities merge every known past, present, or possible future pathological condition. And farther, the causes of all the so-called separate diseases, organic or inorganic, gaseous, fluid, or solid, or naked modes of force, can do nothing more, or nothing less, or nothing different, than to retard, accelerate, or arrest motion, or chemical changes, or change molecular forms of structure in a human body, dead or alive, sick or well.

These facts and inductions make it further apparent that all present classifications of therapeutic, remedial, or hygienic agencies or measures whatever, and the ideals to which they give rise, must also be materially modified, if not wholly abandoned, and others substituted, based on the ideal unities of organic life, to the end that the conceptions to which they shall give rise may correctly represent the facts to the mind. For all that any therapeutical, remedial, or hygienic agency or measure ever has done, or ever can do while the laws now governing the universe are in force, is, —

1st, To promote or retard motion or chemical changes in the molecular forms of the viscera or textures.

2d, To change the molecular forms of structure. These are the naked facts and inductions of modern science, or rather warranted by modern science, in reference to organic life; and they would be speedily recognized and accepted, but for the hypothetical existence of a peculiar force termed vital, manifested nowhere else in the universe, except in living beings. What is called vitality, spirit, or life, is a resultant, and not a cause, of the chemical transformations of the matter composing a human body. Nothing is or can be known of soul, spirit, or life, except through

the forms and motion, or chemical changes, in the molecular forms of structure of the human body. The existence of spirit is self-evident; but no shadow of proof is in existence going to demonstrate that it in any wise controls the physical organization of the human body. This is, through almost innumerable facts, clearly traceable to the ordinary physical forces, in all that concerns its growth, repair, and decay. The sole fact, not as yet accounted for by science, is its molecular forms of structure, as well as physical contour. But that these — physical contour and molecular forms of organic structures — are due to peculiar modes of the physical forces, not as yet identified and separate from them, is well nigh certain; for the constant forms assumed by inorganic matter in passing from fluid to solid states are probably due to a common or uniform form force, operating alike in organic and inorganic natures, just as the chemical transformations of matter are due to a uniform formless or working force, whether in the animal, vegetable, or mineral realms of nature.

It is due to medical science that this advanced ground be speedily occupied. Biology as a science has now no existence in fact; while pathology, therapeutics, and dynamics are simply empiricisms.

Among the cultivated outside of the profession, these truths are, to a greater or less extent, recognized, and hence, with them, the profession, as a body, has but an equivocal status; while the disagreements of the practitioners of its several departments are a standing reproach. A recognition of these, or, if not these, any ideals into which all the accumulated facts of life can be merged, will at once establish scientific order — a standard by which to judge empirical observations and experiences; then disagreements among practitioners of any of the several departments of the healing art will disappear, because they will be impossible.

On a physical basis, physiology, pathology, therapeutics, and organic dynamics may speedily attain a certainty little short of mechanical engineering in our own times. The culture of the age demands it, and sooner or later will possess it. Why does the profession defer it to the future?

MEDICAL MEMORANDA.

Glycerine. — Dr. Unziger recommends to the profession the use of glycerine instead of syrups when prescribing medicines in a liquid form. His reasons are: that it possesses great solvent powers, and mixes well with most substances; that it acts as a great preservative to the medicine by preventing fermentation and decomposition; that in the practice of children especially, it counteracts fermentation in the stomach, acts as a nutritive, and thereby greatly diminishes irritation in the alimentary canal. It has no superior as a vehicle for giving acrid substances, such as tincture of guaiac, turpentine, ammonia, chloroform, acids, etc. In prescribing glycerine for internal use, only the very best ought to be used, as an inferior, impure article would only produce adverse results.

Maxims of Success. — The celebrated Scotch surgeon, Dr. James Syme, used to give his students the following rules to insure success in practice: —

1. Never look surprised at *anything.*
2. Before stating your opinion of a case on your second visit, ascertain whether your previous directions have been complied with.
3. Never ask the same question twice.

Hygienic Treatment of Disease. — The following is an extract from the admirable Address in Medicine, by Dr. Francis Gibson, at the last meeting of the British Medical Association: —

"Side by side with the use of medicine, and not second to it, is the so-called hygienic treatment of disease, — the study and regulation of the vital forces. The influence that the physician exercises over the mind, and through the mind over the body; the soothing or the stimulation of the nervous power; the calming of exaltation or the stirring up of apathy; the quieting of the over-busy brain or the spurring of the flagging will; the repose of over-used powers or the awakening of suspended vital functions; the subduing of the over-sensitive skin, or the stimulating of it where wan, muddy, and lifeless; the limiting of supplies to the over-fed frame or the repair of the wasted body by the proper kinds of food and stimulants; the bringing into play, and so again into existence, muscle that had become wasted and paralyzed by disease, — these are among the aims the physician seeks to accomplish, and these are among the means which he seeks to employ irrespectively, but by no means necessarily, without the use of medicine; these are among the agencies which you hold in your power in the treatment of disease, and that you, each of you, exercise daily in coping with the various forms of malady, of ailment, and of constitution."

Leeches. — Few persons have any conceptions of the magnitude of the leech trade. France is said to consume annually 100,000,000 of leeches, England and Germany the same, and other countries in proportion. From official statistics of France, Germany, Russia, Italy, and Turkey, it has been gathered that the prime cost of leeches sold in Europe exceeds $10,000,000 per annum. Some parts of Australia abound with leeches, those which frequent the Murray River being preferred by the medical faculty to any other known specimen. They bite freely, and leave no inflammatory wound or mark behind. They thus equal, if they do not surpass, the famed freckled leeches of Northern Europe.

Pharmaceutical Homicide. — "Little mistakes" in dispensing medicines are becoming more rather than less frequent. The *New York Medical Gazette* says: "Two more deaths from ignorance or carelessness of druggists' clerks were reported last week. At Batavia, in this State, a young man was given eighty grains of tartrate of antimony in mistake for a dose of salts (so the Albany *Evening Journal* has it, although such an error seems almost inconceivable), death ensuing in a few hours; and in Bridgeport, Connecticut, a girl aged twelve was killed by the substitution of morphine for quinine in compounding a prescription. When shall we have laws prohibiting the dispensing of drugs by any save graduates of a College of Pharmacy?" — And when, we may add, shall we have "Colleges of Pharmacy" that are worthy of the name, so that their graduates may properly be intrusted by law with this responsible business of dispensing medicines?

Singular Cause of Death. — The *Lancet* states that a woman named Cooper, housekeeper to Mr. W. Boyce, at Newmarket, was sitting near a table on which were some poisoned papers for the purpose of killing flies. A fly was seen to go to one of these papers, and then to alight on the woman's nose, which was slightly scratched. The wound became speedily inflamed, in a short time her whole system became affected, and in about twenty-four hours she died.

Carbolic Acid and Street Watering. — Dr. Whitmore, in his Report of the Health of the Parish of St. Marylebone, London, for August, says: "During the summer most of our crowded streets have been watered on alternate days with a weak solution of carbolic acid, as has been the custom for the last four years, and there is no doubt that this excellent antiseptic and disinfectant has been very beneficial in a sanitary point of view. The inhabitants of those streets have often expressed satisfaction at the freshness and removal of disagreeable smells which this acid produces, and they regard it as an addition to their comfort."

QUACK MEDICINES.

Quack medicines, like Macbeth, bear a charmed life. Serious argument, ridicule, the inexorable logic of repeated failures and exposures, have no effect on their consumption, so long as the proprietors supply the "go-power" by untiring advertising. For this reason, we think most of them will survive the following smart attack made on them by the *San Francisco News Letter.* Our contemporary writes: "We have a suggestion to make to the medicine men, which we will preface by the statement that for a considerable part of the nineteenth century we have been taking their prescriptions with an unquestioning and lamb-like compliance that entitles us to a respectful hearing in return. The principal affliction under which our healthless community writhes like a colicky worm is 'ye Nostrum.' Why should it longer writhe? Granted that the community is an ass, which gets itself poisoned by cropping a noxious weed in preference to a healing herb. Asses, on account of their relationship to ourselves, must be tenderly looked after and firmly restrained. There are an infinite variety of ways to restrain them, all more or less ineffectual. Probably the one that is least so is the crunching of their heads with the back of an axe, or some process that shall give a similar result. And this is the method we would employ in dealing with their fellow brutes who stuff their systems with patent medicines and feed the same to their females and young. We would mash their heads. But inasmuch as, under our mawkish civilization, this is quite impossible to accomplish in any kind of peace, there is no choice but to be content with a method less satisfactory to the feelings, but equally efficacious, so far as concerns final results. Our leading physicians of the McNulty-Maxwell stripe should combine in an anti-nostrum society. They might employ an experienced chemist whose duty it should be to carefully analyze every patent medicine in the market, and publish its composition to the world; with some judicious remarks — adapted to the meanest capacity extant — as to the probable or observed effect of taking it into the stomach. There is little doubt, such is the influence of the mind upon the body, that a great multitude of the unlucky wights who have been dosing themselves with these villainous drugs would, upon learning what they have got inside them, keel over and die. This would be a positive blessing. It would materially decrease the vote at primary elections, and would render anti-coolie conventions impossible. It would probably not interfere more than temporarily with the profits of apothecaries, for people would take more medicine of the proper kind. By the same token, it would increase the fees of the regular practitioners. Upon this cogent argument we rest our case."

SCARLET FEVER.

According to the *British Medical Journal*, during the 21 years from 1848 to 1868 inclusive, there were registered in England and Wales 415,982 deaths from scarlet fever and its allied disease, diphtheria. To bring this number down to the present time, exact data are not yet forthcoming; but it may be estimated that at least 40,000 deaths occurred throughout England last year. In the six months ending June last, 13,000 deaths were returned as resulting from scarlet fever and diphtheria, — a number which we suspect, however, to be under rather than over the mark. Here, then, we have an aggregate in round numbers of 470,000 persons who have fallen victims to one type of zymotic disease in the last 22½ years. But what of those whom the diseases attacked, but did not kill outright? On the most moderate assumption, it is probable that at least 5,000,000 of persons in England have, during the last 22½ years, suffered more

or less severely from attacks of scarlet fever and diphtheria. That a considerable number of these persons ultimately perished by other maladies, either induced by the original attack or supervening on a broken constitution, must undoubtedly be taken for granted.

Speaking of the propagation of the fever, the *Medical Gazette* says: "It is spread by personal carelessness, by neglect, and by recklessness of individuals as to the public safety. Scarlet fever is propagated from person to person by culpable ignorance and criminal neglect. Cleanliness and general sanitary regulations are of use in mitigating the severity of the disease, but are no bar to its propagation. Scarlet fever is one of the most intensely and continuously contagious diseases. From the outset of the disease till the completion of the subsequent process of peeling the skin, the patient, his clothing and discharges, and the light scales which are diffused in the atmosphere from his poisonous surface-skin, are pregnant with poison. Not only should he be carefully isolated; not only should his clothing and all that comes in contact with him be carefully and thoroughly disinfected; not only should his body be anointed, as Dr. Budd has recommended, with oil to limit the aërial diffusion of the epidermal scales, but the utmost care should be exercised by the persons attending him not to become carriers of this virulent and subtile poison. To send to the laundress garments fatal as those of Dejanira, to expose in a public carriage or a crowded waiting-room the fertile sources of a deadly and volatile poison, are terrible offences against the public safety. They are constantly and carelessly committed, and it is thus that scarlatina is spread."

AN EXCESSIVE DOSE OF CHLORAL.

Dr. James Rodman, of Hopkinsville, Ky., relates the following case in the *American Practitioner*: —

Forty-five grains of hydrate of chloral was prescribed for an insane gentleman, of spare frame and delicate organization. This dose had on several former occasions been administered to him with the effect of producing from seven to nine hours of unbroken sleep. On this occasion, the first dose of forty-five grains proving insufficient, the nurse, without consulting Dr. R., allowed the patient to take two hundred and twenty-five grains more, making in all two hundred and seventy grains in less than two hours. Deep sleep followed, which was not regarded with concern by the attendants until seven or eight hours had elapsed. Dr. R. then found him sleeping heavily but quietly, his skin rather warmer than natural, pulse less frequent than in health, but full and strong; his pupils were sluggish and contracted, conjunctiva injected, respiration normal in character and fifteen in a minute, and he could with difficulty be aroused to any sense of his surroundings. Sleep continued eighteen hours, during which time the patient was aroused only occasionally by considerable effort, and swallowed a little water.

The treatment consisted of cold affusions to the head, not frequently repeated, and he was walked at short intervals between two assistants, and vapor of ammonia applied to his nostrils. This expectant treatment was adopted, as the condition of the patient was by no means alarming, and the lapse of time after the exhibition of the drug rendered an antidote unavailing, even if he had known of any that had been properly demonstrated to possess antidotal properties. When the patient awakened, he presented the appearance of a man recovering from profound alcoholic intoxication. There was no headache nor nausea. He had a keen appetite, healthy pulse, warm extremities, but a constant sense of chilliness, that passed away in a few hours.

This case is very remarkable for the absence of those alarming symptoms which we should naturally expect to result from such an enormous dose of this substance.

THE TREATMENT OF THE INSANE WITHOUT MECHANICAL RESTRAINTS.

Dr. Henry Maudsley, writing on this most interesting subject in the London *Practitioner*, says: "The principle of the non-restraint system, in the true acceptation of the term, is, while avoiding a meddlesome interference, to make all the surroundings of the poor lunatic as tranquil, as orderly, as gentle, as may be consistent with his proper care, — to counteract the commotion in him by an absence of commotion in what is around him. The lunatic cannot, any more than the sane person, resist the steady influence of his surroundings; he assimilates them unconsciously, and they modify his character for good or for evil. How little a system of mechanical restraint fulfils the conditions of the just principle of treatment is so plain that a wayfaring man, though a fool, can hardly fail to see it. An excited, active patient, urged by an uncontrollable instinct of movement, desiring and needing above all things freedom of limbs, is secured hand and foot by mechanical appliances — with what result? That he is provoked into furious mania, expends his energy in shouting and raving, and becomes dirty in his habits, — dirtiness in some shape is, in fact, unavoidable under such circumstances. . . . There can be no greater fallacy than that of supposing what is called a moderate use of mechanical restraint to be consistent with a general plan of treatment in other respects humane and beneficial. It must be dispensed with altogether, or deterioration will ensue in the patient, and all kinds of neglect and tyranny will be engendered by degrees, until restraints become the usual substitutes for forbearance and watchful attention. . . . It is necessary that the abolition of restraint should be absolute to be efficient; the principle of the non-restraint system will admit of no compromise. . . . . I do not hesitate to express a strong personal conviction that the use of mechanical restraint in any asylum, public or private, is an indication of a badly managed institution, and that its use in the treatment of private cases is unnecessary and prejudicial. Where it is entirely dispensed with there will be less excitement, fewer scenes of violence, less need of secluding patients, and earlier and more numerous recoveries than where it is in use. For it is not only an evil itself, but it is the fruitful parent of a multitude of ills, not the least of which is the certain deterioration of all who have any part in its employment, whether suffering or doing."

THE THERMOMETER IN MEDICINE.

The *British Medical Journal* expresses the hope that "it will not be long before every intelligent mother of a family is familiar with the use of the thermometer for the discovery of disease. In many respects, it is far more reliable than the tongue or the pulse. As a means of ascertaining when it is desirable to consult a doctor, and when advice may be deferred with safety, it would be invaluable. By its aid the difference between insignificant skin-rashes, which will disappear in a day or two, and those which imply a constitutional fever, may usually be satisfactorily determined. Under many circumstances, the early discovery that a child was sickening for scarlatina or measles might be of great importance. We hope that before long a few brief rules adapted for home employment will be prepared, and that, aided by them, the mothers and nurses of our land will at once commence the acquisition of a kind of experience which will become every year of increased importance. In addition to its practical value in reference to the health of their households, we must also add that all who becom familiar with the facts of human thermometry mu learn some very interesting lessons in physiology."

VALUABLE FORMULÆ.

Cologne Water. — The following gives an arti cle of superior quality, if the oils are pure and th alcohol good: —

Pure Alcohol	6 gallons.
Oil of Neroli	4 ounces.
" " Rosemary . . .	2 "
" " Orange . . .	5 "
" " Citron . . .	5 "
" " Bergamot . . .	2 "

Mix with agitation; then allow it to stand for few days perfectly quiet before bottling.

The following affords a good article, but no equal to the preceding: —

Pure Alcohol	6 gallons
Oil of Neroli	2½ ounces
" " Rosemary . . .	2 "
" " Orange peel . . .	4 "
" " Lemon . . .	4 "
" " Bergamot . . .	4 "

Treat in the same way as the first.

Camphor Ice. — Expressed oil of almonds an rose-water, each 1 pound. White wax and sper maceti, each 1 ounce. Camphor, 2 oz. Oil of rosemary, 1 dr. Melt together. Glycerine may b substituted in part for the oil and rose-water.

Tincture Kino. — In our last we referred to a inquiry for a method of preventing the gelatinizin of Tinct. Kino. A friend in Brooklyn, N. Y., send us the following formula: —

Kino	℥iss.
Logwood, in coarse powder .	℥ss.
Alcohol, dilute	q. s.

Moisten the logwood with dilute alcohol, an pack in a glass percolator; dissolve the kino b trituration in successive quantities of dilute alcohol pour this solution and dilute alcohol over the log wood until one pint of tincture has passed.

Our correspondent says that tincture prepared a year ago by this formula is now just as liquid as when first made, while that made according to th Pharmacopœia became in a short time so thick that it could not be poured from the bottle.

Burns and Scalds. — Dr. Ferguson gives th following recipe which he has tested in the severes cases of burning and scalding from railroad an steamboat accidents with invariable success: Gly cerine, five ounces; white of egg, four ounces tincture of arnica, three ounces. Mix the glycerin and white of egg thoroughly in a mortar, and grad ually add the arnica. Apply freely on linen rags night and morning, washing previously with warn castile soap-suds.

The celebrated English surgeon, Mr. Skey, recom mends the application of a solution of nitrate of sil ver in a proportionate strength, varying from five t twelve or more grains to the ounce, according to th extent and severity of the burn and the age of th patient. The whole surface of the burn should b brushed over with the solution, cotton-wool applied and a moderate opiate administered in a glass of brandy and water, proportioned to the age and hab its of the patient, with the object of counteracting the sense of chilliness that will otherwise necessarily follow in all these cases.

Many will recollect the anecdote told so often by Dr. Chapman, in regard to himself, when called to visit a little boy who had swallowed a silver twenty-five-cent piece. "Madam," said the renowned joker, in all solemnity, "was the piece good?" "Indeed it was, sir," replied the surprised but excited lady, "I got it myself from the mint." "Then, my dear madam," said Dr. Chapman, "if the money was good, give yourself no further uneasiness, for *it will certainly pass.*"

Boston Journal of Chemistry.

VOLUME V. BOSTON, FEBRUARY, 1871. NUMBER 8.

Familiar Science.

THE CLOTHING WE WEAR.

WE seldom pass through the thoroughfares of a great city without thinking how much the woolen, cotton, silk, and linen fabrics which the crowd of men, women, and children carry about with them upon their persons have to do with their health, comfort, and success in life. Clothing is used not only for warmth, but to secure coolness and to adorn the person. It also serves an important end in keeping the body clean; for with our ideas of cleanliness, if the whole surface were exposed, it would need as frequent washing as do the face and hands, which we leave bare. In our rigorous northern climate, clothing is worn chiefly for the sake of its warmth; and this is indeed the most important point which demands consideration. The human body is a singular machine, and no function of its complex organization is more wonderful than that connected with the production of animal heat. We are warmed by the process of combustion as truly as are our workshops and dwellings; but the furnace within us is a far more perfect apparatus than anything ever constructed through human ingenuity. The regulation of this internal combustion is so beautiful and exact, that the heat of the body in its normal condition never rises above or falls below 98° F. Place a thermometer under the arm so that it will be fully influenced by the animal heat, and it will rise to 98° and remain thus, no matter whether it be summer or winter. Upon our common thermometer this temperature is marked "blood heat," and it remains a fixed point in the scale. We may take up our residence within the arctic circle, or directly under the equator, and there will be no change in the internal temperature of the body. To keep up combustion, and maintain warmth in our dwellings, we use coal or wood as fuel; the body requires more refined combustible materials, such as beef, mutton, poultry, bread, butter, and vegetables, articles which we class as foods, and which are daily placed under the influence of the digestive processes in the stomach. But the stomach is not the furnace where these substances are burned to warm the body. The fireplace or furnace of the body is in the capillary system, or in the minute, invisible vessels which ramify through every part of the organization. The food we consume is not burned directly, but the tissues which are formed from the food are undergoing the process of oxidation or burning every moment of our lives, and from this burning the body is warmed. Every part of us where blood-vessels are to be formed, every part where nervous influence is perceptible, every organ, every tissue,—muscle, and brain, and nerve, and membrane,—waste away like a burning taper, consume to air and ashes, and pass from the system rejected and useless; and if we did not repair the waste by supplying food, the body would "burn up" as truly as if consumed by a blazing pile. Starvation is a burning process; and those who perish from want of food may be said to die from slow combustion. But we must not be enticed away from the topic which it was our purpose to consider.

Clothing is composed of a variety of materials, and these are used with reference to their influence upon the body. Cotton and linen are cooler than wool or silk, and consequently in this climate we prefer the latter in winter and the former in summer. The former are bad conductors of heat, but the animal products, the wool and the silk, are much worse. Clothing serves the same purpose for the body as coverings of wool or hair felting do for steam or hot air pipes, namely, to keep in the heat, or prevent loss by radiation. The worse conductor any substance may be, the warmer it will prove as clothing. Linen jackets and muslin dresses take the place of cloth overcoats and thick shawls in summer, because they are better heat conductors than the heavy woolen garments. In winter we desire to retain as much animal heat as possible, and so we don the very imperfect conducting substances of wool and silk.

The color of clothing is by no means a matter of indifference. White and light-colored clothes reflect the heat, while black and dark-colored ones absorb it. White is the comfortable and fashionable color for clothing in summer. It reflects heat well, and prevents the sun's rays from passing through and heating the body. If white is the best color for summer, it does not follow that black is the best for winter. It must be remembered that black radiates heat with great rapidity. Give a coat of white paint to a black steam radiator, which is capable of rendering a room comfortably warm at all times, and the temperature will fall at once, though the heat-producing agency remain the same as before. A black garment robs the body of a larger amount of heat than white, and consequently the latter color is the best for winter garments. It is the best color for both summer and winter. Although this statement may seem like blowing hot and cold, it is nevertheless true. Let those who are troubled with cold feet, and who wear dark socks, change to white, and see if the difficulty is not in part or wholly removed. Utility in color is confined to the different shades merging from dark into light; but we find in connection with dress all the beautiful tints of the rainbow, and these are used for the ornamentation of the person. The rich and varied colors which are so extensively worn are by no means to be condemned; adornment of the person to a reasonable extent is commendable. We all love the beautiful in nature, and what adds so much to the attractiveness of woman as the ribbons and scarfs, stained with magenta, mauve, or solferino, which adorn her person? Deep in the instincts of our nature is laid the admiration of color; and we love beautiful flowers and birds and — beautifully dressed ladies.

The abuses in dress must not pass unnoticed. The tight waists, the low necks to dresses, and the high-heeled shoes are most flagrant abuses, and ought not to be longer tolerated. We shall not quarrel with the little jaunty hats of the ladies; for they are indeed pretty, and no harm results from them, as of all parts of the body the head needs the least clothing. But, to pass to the other extremity, we have to say that the detestable high heels to ladies' boots and shoes, running as they do down almost to a point, are spoiling the gait and ruining the ankle-joints of children and young misses. We are careful to order our shoemakers to remove such heels from shoes before permitting them to be brought into our dwelling. Heels of moderate height and good breadth are of great service in elevating the feet, so as to avoid direct contact with moist earth, and they also give support and afford firmness to the step. Why should Fashion push good devices to absurd extremes? We must aid in dethroning the tyrant when her decrees lead to the physical or moral injury of the race. The present fashion of leaving the neck and the upper part of the chest bare, is fraught with evil consequences. It would be less objectionable in countries uniformly warm; but that our daughters, here in this frigid and changeable climate, should constantly expose to chilling winds a vital part of the body, is one of the evils of fashion which should be discountenanced by every mother, and father, and brother.

No part of the dress of men is really more absurd than the hard "stove-pipe" hat so generally worn; and yet all attempts to subvert it have proved abortive. For thirty years we have worn this kind of head covering, and we like it better than any other; we have tried hard to like the low soft hats, but we cannot; and this is the experience of thousands. Absurd as the high, hard hat is, it does keep the head more comfortable, it does maintain a more equable temperature, it does *feel* better, than any other form of head covering; and so let us continue to knock them against beams in attics and the branches of trees. If they serve a good purpose in brushing cobwebs from the roofs of old garrets and stables, they also protect us from bad bumps, and keep our heads comfortable.

There is much to be said upon the subject of dress, but we have not room for further remarks at present.

ALLYL.

To many of our readers allyl is probably not a very familiar word; but, like many terms found in the vocabulary of the chemist, it is connected with sundry matters of every-day interest. It is the name of one of a large class of vegetable oils which consist of only two elements, hydrogen and carbon. Many of these volatile oils are exquisite perfumes,—as, for instance, those to which the rose and the lemon owe their fra-

grance; but allyl and its compounds exhale an odor of another sort, and by no means so generally acceptable to sensitive nostrils. The onion and the garlic derive their smell and their flavor from the *sulphide of allyl*, a combination of sulphur and this hydrocarbon allyl. But in these plants we do not have the compound in its full pungency. To obtain an ounce of the odorous oil, we must distill the sweetness of thirty or forty pounds of garlic or fifty pounds of onions. *Assafœtida*, which in its commercial form is the dried juice or sap of an Asiatic plant, contains a similar compound of sulphur and allyl. The characteristic flavors of horse-radish and mustard are likewise due to allyl united with sulphur and a substance of much chemical interest, known as cyanogen.

These plants containing allyl are very widely distributed over the earth, and from the earliest times have been more or less popular as articles of food. When the Israelites were wandering in the wilderness, we are told (Numbers xi. 5) that they murmured, saying, "We remember the cucumbers, and the melons, and *the leeks, and the onions, and the garlic.*" These alliaceous vegetables were even objects of worship among the ancient Egyptians, which suggested the satirical exclamation of the Roman poet: —

"O happy country! where the gardens bear
A crop of gods through all the lengthening year."

The assafœtida is rather too strongly flavored to be tolerable to European palates, but in Asia it is a favorite condiment for food. The Frenchman makes the garlic an ingredient of countless dishes, but generally in moderation, and delicately mingled with other flavors; with the Spaniard the garlic and the onion are every-day relishes and more freely used; while, if we cross over into Africa, we find these vegetables the seasoning of the universal food throughout the whole region from the Pillars of Hercules to the mouth of the Nile. The Teutonic races, with their Anglo-Saxon offshoots, make up in their fondness for mustard for their less ardent devotion to the onion; but the latter is by no means an insignificant item in their food. England has to import hundreds of tons of onions from Spain and Portugal, to eke out the supply from home production; and in this country we consume a good part of our large onion crop, though we have a surplus for exportation.

Man has not unwisely "followed his nose" in selecting these strong-smelling plants as articles of food. Human instinct, in this case as in so many others, has proved a trustworthy guide; for the onion is one of the most nutritious of vegetables. It contains a large quantity of gluten (from twenty-five to thirty per cent. of the dried bulb) and of uncrystallizable sugar. In Spain and Portugal, the working man who makes his dinner of a piece of bread and a raw onion, eaten as a Yankee would eat an apple, does not make so poor a repast as we might at first consider it. Like plain bread and cheese, it is a cheap and simple meal, but one which is nourishing and strengthening. With such a diet a man may work hard year after year, and yet "hold his own" quite as well as some of his brethren in other lands who can command more varied and more costly fare.

NAPHTHALINE may be used instead of camphor as a protection against moths and other insects.

OZONE.

WHEN an electrical machine is worked, a peculiar pungent odor is produced, which has sometimes been called "the electrical smell." It has been found, however, that the same odor can be developed by other means, as by allowing phosphorus to remain for some time in moist air or oxygen, and by the slow combustion of ether and certain other volatile liquids. This odorous principle has been the subject of much investigation during the last thirty years, especially by Prof. Schönbein, of Basle, to whom it owes its name of *ozone*, from a Greek word (ὄζω), meaning *to smell.* After so much research, it might be supposed that we should know all about it, but ozone is still one of the mysteries of modern chemistry. Prof. Balfour Stewart, writing on the subject only a few months ago, says that it "is supposed to be a peculiar modification of oxygen, into which ordinary oxygen is converted by the passage of the electric current;" but it is now pretty generally conceded that ozone *must* be an allotropic form of oxygen, unless oxygen, instead of being an *element*, is a *compound*, of which ozone is one of the constituents.

There are several of the elements, — sulphur, phosphorus, and carbon being familiar examples — which are capable of existing in states so unlike that they would naturally be taken for radically different substances. The *diamond, plumbago* (or *black lead*, as it is popularly called), and *charcoal* are three such states of carbon, very different in their appearance and properties, and yet easily proved to be chemically one and the same element. These states are called *allotropic*, from two Greek words meaning *of a different character*, and the capability of existing in such states is known as *allotropism.* In the case of sulphur and phosphorus the element can be readily changed from one of these states to another, and back again; and it can be proved beyond all question that we have the very same portion of matter, with nothing added to it or taken away from it, from the beginning to the end of the experiment. *How* this can be we are absolutely ignorant: we give a name to the phenomenon, but as yet we have no knowledge whatever of its nature.

That ozone is either oxygen or a constituent of oxygen would appear to be proved by the fact that it can be produced by sending electric sparks through pure, dry oxygen sealed up in a glass tube. If this be done, the bulk of the gas is diminished somewhat, and the presence of ozone can be detected by the smell, as well as by chemical tests.

Assuming ozone to be oxygen, it is a remarkably energetic form of that element. It oxidizes metals on which ordinary oxygen does not act at all; indeed, it attacks all the metals except gold, platinum, and the rare metals chemically related to platinum. It corrodes cork, india-rubber, and most other organic substances; and hence it is a powerful bleaching and disinfecting agent. When breathed, even in a very dilute state, it is exceedingly irritating to the lungs, its effects being much like those produced by chlorine. Its density is greater than that of oxygen, — just one half greater, according to some authorities.

Ozone instantly decomposes the iodides of the metals, and this fact has suggested a ready test for its presence. A slip of paper dipped in a solution of iodide of potassium and starch-paste is turned blue if exposed to its action. The ozone unites with the potassium, liberating the iodine, which forms a blue compound with the starch. Since paper thus prepared is often turned blue by exposure to the atmosphere, it is supposed that ozone is present in the air in variable quantity. But as the same effect may be produced by other oxidizing agents sometimes found in the atmosphere, this test is not conclusive, unless confirmed by others. On the whole, the weight of evidence is in favor of the theory that ozone *is* a constituent of the atmosphere, and that the variation in its amount may have an influence upon health. It may often act as a disinfectant by oxidizing and destroying the organic "disease germs," if such there be, floating in the air. It is claimed that infectious diseases have sometimes abated with the coming of an ozoniferous wind. On the other hand, the irritating influence of the gas may, as some physicans believe, give rise to diseases of the respiratory organs. There is considerable evidence that colds, influenza, sore throats, and kindred complaints have been especially prevalent at times when the amount of ozone in the air was greater than usual.

It is not improbable that ozone may yet play an important part in the arts. If it can be cheaply obtained in considerable quantities, it may come to be used extensively as a bleaching agent. If it does not take the place of chlorine, it may be made available where chlorine cannot be employed. An apparatus for producing ozone by means of an induction coil has been devised, which promises to furnish the gas abundantly at small expense; and a patent has been taken out in England for the application of ozone to the bleaching of syrup in the manufacture of sugar. We shall not be surprised if the industrial uses of ozone should be as rapidly extended as those of certain other chemical agents have been in our day. Iodine, bromine, paraffine, glycerine, and carbolic acid are but a few out of many illustrations we might give of substances that a few years ago were little more than curiosities of the laboratory, while now their commercial importance is immense. Ozone may soon be added to the same list.

In this familiar account of ozone we have said nothing of *antozone*, which many chemists believe to be another allotropic form of oxygen, produced simultaneously with ozone and often confounded with it, but distinguishable from it by certain chemical tests. Its properties have been less thoroughly investigated than those of ozone. We know little enough about that, but we know even less about antozone. It is, nevertheless, a very interesting substance, and we shall speak of it hereafter.

THE STEREOSCOPE.

MR. A. C. NICHOLS, of Leavenworth, Kansas, sends us the following novel and interesting suggestions with regard to this instrument: —

One idea the stereoscope suggests is, that our involuntary seeing — that is, our seeing least changed by directed attention — is a vital act; in other words, the convergence of the lines of vision from our two eyes just necessary to prevent seeing double is such an act. But it is an act of life so constant and unremitting, in our wakeful moments, as to be far less apprehended by us than the motion of the lungs, or the beating of the heart; an act similar to that which, in our wakeful period, holds open our eyes.

I think there are moments when this life tension

is somewhat let down, and that this diminution of tension may be easily detected by a careful observer. In the half-asleep period, just between slumber and waking, if there be sufficient languor, objects will be seen double, and just the distance apart at which the stereoscope presents them.

We are told, moreover, that certain abnormal conditions of the brain give rise to double vision; and we all know that this is said to be one of the effects of intoxication.

Again, medical works state that the extract of Gelsemium is one of the most powerful relaxing agents known; and it is recommended to administer it in small doses, repeating them at short intervals till the patient complains of double vision.

Now I believe that in all these cases the vital or semi-vital act, by which the axes of our two eyes are sufficiently converged for seeing objects solid or single, is interfered with by relaxation or languor, normally or otherwise brought about.

It may be said that while the head, with its two eyes, is constantly, by mechanical formation, the original of the double-tubed stereoscopic camera, the final stereoscopic result — brought about in the mechanical world by a separate instrument — is in animate vision only realized in connection with certain degrees of wakeful attention.

Another idea with me is, that this delightful little instrument, the stereoscope, may, in the hands of astronomical calculators, be made to give us the true shape of our moon. Some astronomers hold that she is not exactly spherical, but egg-shaped, with the pointed end toward us. Might not the stereoscope settle this question?

It is well known, among photographers, that if the picture of a light-stand, whose top is round, be taken for the stereoscope, it will appear in the stereoscope in positive relief, and the top *round*, when the camera tubes were used two and a half or three inches apart; but if the camera views be apart as many or double the number of *feet*, the result in the stereoscope will be an *oval*-topped stand, sharply standing with its longest diameter pointing toward the observer, as though the circular top had been pushed out of round by a lateral pressure. In this case, the relief is simply exaggerated. The human face, treated in the same way, appears in the stereoscope sharpened or distorted from the excess of relief.

The fine point to calculate in photographing the moon for the stereoscope would be to find just how much of her libration is needed for a true production or representation of her shape; and also whether this could be secured when she is at exactly the same point in her passage from new to full; and at the same elevation in the heavens, between zenith and horizon.

Again, besides the misrepresentation of form caused by taking the two pictures for the stereoscope from widely separated points of view, there is a belittlement of the object represented. For instance, if a considerable portion of a city be taken from quite an elevation, with widely separated view points, the stereoscope will make the buildings look like martin-houses thickly set along narrow footpaths.

If, in taking a stereograph of the moon, it be possible to obtain too great a relief by using her whole libration as difference between the two camera views, thereby gaining the advantage of a "giant vision, with eyes thousands of miles apart," as Sir John Herschel aptly says I apprehend that, instead of being conscious of being magnified ourselves, we should only find the moon diminished to a foot-ball.

HAIR-BRUSHES are best cleaned by washing them in saleratus or soda-water, which removes all the oily coating. The alkali of course unites with the oil to form *soap*, which aids in the cleansing.

NOTES ON FAMILIAR SCIENCE.

TO FREEZE WATER. — At this time of year most of our readers can suggest a ready way of performing this experiment; but in hot weather or in a warm room they might not find it so easy a feat. They are aware, however, that evaporation is a cooling process, just as freezing is a warming process; in other words, that a liquid in passing to the gaseous state *absorbs* a good deal of heat, while in passing to the solid state it *gives up* heat. Taking advantage of this simple law, water may be readily frozen by the evaporation of ether. Put the water in a small test-tube; and place the test-tube, surrounded with cotton moistened with ether, in a wine-glass or tumbler. Put the nozzle of a bellows into the cotton, and blow vigorously. The current of air passing over the cotton acts on a very large surface of ether, which is thus evaporated fast enough to freeze the water in the tube.

A TRAP FOR SUNBEAMS. — In the JOURNAL for November, we explained the difference between luminous and obscure heat, and how the heat of the sunbeams is caught and confined by hot-houses, and also by the watery vapor in our atmosphere. Saussure illustrated the same thing by an interesting experiment. He made a wooden box, blackened within, having one of its sides formed of three panes of glass, separated by thin layers of air. He then put a vessel of water in the box, and exposed the glass side to the rays of the sun; and in this way he succeeded in making the water boil. The luminous heat easily passed in through the glass and the air, and was absorbed by the blackened surface; but when radiated back as obscure heat, it could not escape from the box, and after a time it had accumulated sufficiently to boil the water.

Ericsson has long been experimenting upon means for utilizing the solar heat, and has succeeded in making an engine whose motive power is sunlight. The full details of his invention are not yet made public, but it is not unreasonable to hope that it will prove of great practical importance. The amount of *force* in the solar rays that are virtually wasted on the surface of the earth is almost beyond calculation; and if even a small fraction of it can be made available for mechanical purposes, the gain to industrial interests will be immense.

WATER IN PLANTS AND ANIMALS. — Hamlet complained of "this too, too solid flesh" of ours, but it is not so very far from being fluid, after all. Organic bodies in general are made up of a very little solid matter to a great deal of liquid. To quote from Rolfe and Gillet's *Handbook of Chemistry*, "Water constitutes the greater part of all plants and animals. The human body is four fifths water. In many of the lower animals the proportion is much greater. From a sun-fish weighing 30 pounds, only 240 grains of solid matter were obtained; so that water makes up about .999 of the weight of such animals. The vegetable substances which we use for food contain almost as large a percentage of water. In potatoes, the fraction is .75; in apples, .80; in turnips, .90; in watermelons, .94; and in cucumbers, .97."

HOUSEHOLD RECIPES.

REMEDIES FOR POISON BY IVY. — 1. Olive oil is said to be a sure cure for the effects of the Poison Ivy or Poison Oak (*Rhus toxicodendron*). In severe cases it is to be taken internally as well as applied externally. Dose, two table-spoonfuls three times a day, keeping the affected parts well oiled all the time. Anointing the exposed parts with the oil will prevent poisoning.

2. Take a handful of quick-lime, dissolve in water, let it stand a half-hour, then paint the poisoned parts with it. Three or four applications never fail to cure the most aggravated cases.

TO MAKE OLD KID GLOVES NEW. — Make a thick mucilage by boiling a handful of flaxseed; add a little dissolved soap; then when the mixture cools, with a piece of white flannel wipe the gloves, previously fitting to the hand; use only enough of the cleaner to take off the dirt without wetting through the glove.

HOW TO SAVE YOUR SHOE SOLES. — Melt together tallow and common resin, in the proportion of two parts of the former to one of the latter, and apply the preparation, hot, to the soles of the boots or shoes — as much of it as the leather will absorb. One farmer declares that this little recipe alone has been worth more than the cost of five years' subscription to the newspapers publishing it.

A REMARKABLE SPRING.

A CORRESPONDENT sends us the following account of a remarkable spring in Texas: —

"About sixty miles north of Galena, near the town of Liberty, there is a spring, the water of which is quite acid, simulating lemonade, and those who taste it like it so much that they drink it almost immoderately. When you feel hot, it is quite delicious; and under any circumstances, whether you are hot or cold, the drinking of it produces perspiration, with no unpleasant effects afterward. The spring has no apparent outlet or inlet. It is probably sixty feet across it, and it is covered with a white froth or foam, which upon close examination appears like cream of tartar on a wine-cask. It kills insects, worms, and other small animals that come near and use it. No fish or other evidence of life is seen within its waters."

BIG TREES IN MISSOURI. — It is popularly supposed that California has the biggest trees in the world; but Prof. Swallow, of the Missouri Geological Survey, claims the distinction for his own State. He gives the following actual measurement of trees in southwest Missouri: —

"The largest is a sycamore in Mississippi County 65 feet high, which, 2 feet above the ground, measures 43 feet in circumference. Another sycamore in Howard County is 38 feet in circumference. A cypress in Cape Girardeau County, at a distance of one foot from the ground, measures 29 feet in circumference. A cotton-wood in Mississippi County measures 30 feet around at a distance of 6 feet above the ground. A pecan in the same county measures 18 feet in circumference. A black walnut in Bentou County is 26 feet in circumference. A tulip tree (poplar) in Cape Giradeau County is 30 feet in circumference. There is a tupelo in Stoddard County 30 feet in circumference. There is a hackberry in Howard County 11 feet in circumference. A Spanish oak in New Madrid County is 26 feet in circumference. A honey locust in Howard County is 13 feet round. There is a willow in Pemiscot County that has grown to the size of 24 feet in circumference, and 100 feet in height. Mississippi County boasts of a sassafras that must be king of that tribe; it measures 9 feet in circumference. In Pemiscot County there is a dogwood 6 feet in circumference. In Mississippi County pawpaws grow to a circumference of 3 feet, and grape-vines and trumpet creepers to a circumference of 18 to 20 inches."

RELIGION AND SCIENCE. — The devout man trembles without cause at the progress of science; science has power and permanence only as it is true; and, so far as true, science can only be a reading of part of the thoughts of God. The man without religious faith boasts without cause over the reduction of all things to scientific law. Scientific laws constitute only the *grammar* of the Divine speech. For the meaning of the creative word, we look much higher. — *Rev. Thos. Hill, D. D.*

The Arts.

MEMORANDA IN THE ARTS.

Adulteration of Aniline Colors. — The *Manufacturers' Review* states that aniline dyes are now frequently adulterated, chiefly with sugar and starch, and gives the following methods for detecting the fraud: —

"To test for sugar, dissolve a quantity of the aniline dye in water, add a little yeast, and place the solution where the temperature is between 68° and 77° F. If sugar is present, fermentation will set in in a few hours, the progress of which will be indicated by the abundant evolution of bubbles of carbonic acid gas.

"In testing for starch, we must remember that aniline colors are soluble in alcohol, while starch is not. In this case, therefore, we take a quantity of the aniline color, pour alcohol on it till it is saturated with color, and then pour it off from the undissolved residue. The treatment with alcohol is repeated till the residue is no longer colored. We may then examine the residue under the microscope, or by boiling it with hot water, to satisfy ourselves that it is really starch."

If the insoluble residue does not appear to be starch or sugar, further chemical examination will be necessary. It is said that soda salts are often used to adulterate aniline dyes, and that their amount sometimes rises as high as 20 per cent.

Vegetable Down. — From the same excellent authority we learn, that in Europe the decreasing supply of horse-hair from America and the increased demand for the article have led to many efforts to find a good substitute for it. Most of these have proved failures; but a Mr. Kratzenstein, of Amsterdam, has prepared a "purified vegetable down" which appears to be even better than the horse-hair itself. "This down is the envelope of the cotyledon of an Indian fruit, for the cleansing and working of which Mr. Kratzenstein had a special machine constructed. The advantages claimed for this material, which is offered on its own merits, are — great durability; greater lightness, as a mattress requires, according to its size, from six to eight pounds less of it than it would of horse-hair; it is easily worked and reworked, requiring no preliminary preparation; greater cleanliness. Being a purely vegetable article, it cannot become the home of moths or other vermin. It costs about 38 cents (gold) per pound."

Russian Cotton Factories. — Russia has 667 cotton factories, employing 180,000 operatives. Before the war in this country, cotton manufacture had scarcely commenced in Russia. During that period, however, the Russians began to manufacture Bokhara, Persian, Indian, and other cotton; and it is said that their factories are now the most magnificent in the world, exceeding in style and completeness even the English establishments. The products amount to $50,000,000 annually.

Petroleum as Fuel. — There is a fair prospect at last that crude petroleum can be used advantageously as fuel for steam boilers. The great difficulty hitherto has been the clogging up of the tubes used for feeding the flames by a deposit of solid carbonaceous matter. This obstacle has at last been removed, and there is a factory in Philadelphia which is running night and day with no other fuel. The fires have now been running six months continually. There is no smoke from this new fuel, no gas, and no trouble in feeding the furnaces; the engineer is also the fireman, as he has only to turn a stop-cock to increase or diminish his fire. Having no ashes to clean out, and being able to keep his engine room in good order at all times, the smell of the burning oil is scarcely perceptible. This material for generating steam is likely to prove a great saving in large factories, as petroleum costs only about half as much as coal when used as fuel, with a very large saving in labor. It generates steam much more rapidly than coal, and with ordinary care is just as safe to use. If it can be used on ocean and river steamers, much of the room required for coal can be devoted to stowing cargo, thereby materially increasing the profits of the voyage.

Lively Work on the Wires. — There was quite a rivalry among the telegraph companies between Washington and New York in transmitting the President's Message this year. The document contained about 9,000 words, and was transmitted over 10 wires by the Western Union Company, dropping copies at Baltimore and Philadelphia, in 37½ minutes, or at the average rate of 25 words per minute on each wire.

The entire message was transmitted by the Bankers' and Brokers' and the Franklin Companies in seventy minutes, employing two wires each. This was at the rate of 33 words per minute.

The Franklin Company used two wires until the message was completed, and a third wire for 15 minutes, the average time being 70 minutes and the average speed 28 words per minute.

The Bankers' and Brokers' Company used two wires, the average time being 70 minutes, and the average speed 35 words per minute. One of these wires averaged 39 words per minute.

Household Steam-engines. — Some months ago, we referred to the fact that steam-engines of about one "Biddy" power had been made for domestic use in France, and that they gave good satisfaction wherever they had been tested. More recently we have met with the following description of one of these engines in an English paper: —

"The apparatus consists of a small vertical boiler, heated by several Bunsen burners, the supply of gas to these burners being governed by a simple automatic arrangement dependent for its action upon the pressure of the steam. Thus, as this pressure rises, the supply of gas is diminished, the adjustment being such that practically the steam is maintained constantly at any pressure to which the apparatus is set. The engine, which is of very simple construction, is carried by the boiler, and the latter is of such capacity as to contain sufficient water for a day's supply. In using the apparatus, all that is necessary is to charge the boiler in the morning and light the gas, and the engine will run the whole day without further attention."

A New Field for Chloral Hydrate. — It appears that the fame of this remarkable compound is not to be confined to medical circles. It has already found its way into the laboratory of the photographer, and we will not venture to predict in what other art processes it may hereafter be used. The *Photographische Archiv* mentions, that to freshly prepared and slightly colored collodion (iodo-bromized) one per cent. of chloral hydrate was added. With a neutral silver bath it gave a good white film. The developer consisted of sulphate of iron and acetic acid. The plates were considerably more sensitive than those prepared without the chloral hydrate. The plates worked very clean.

COTTON-SEED OIL IN ENGLAND.

The Liverpool Circular of Alexander S. Macrae, under date of Nov. 19th, says: —

"The cotton-seed oil of the Southern States has a great future before it, second only in importance to the gigantic petroleum trade of the Northern States. Its sweetness, utility, and price are now commending it everywhere; and though in England we are manufacturing 20,000 tons annually (chiefly from Egyptian seed), the quality is not to be compared to the American, as the following values will testify. The price of English to-day is £34, at which it is slow; the value of American £36 to £4[illegible] per ton, at which it is in strong demand.

"The range of quotations for American oil begins from the worst of it (which eclipses any of ours) to the best of it, — that is, from ordinary yellow to the fine bleached. The bleaching of this oil is of the veriest importance, and, whether effected by the sun or chemically, will have a marked advantage from Southern climes. Our consumption for it is practically inexhaustible — we use it for soap, for salads, for lubricating, and for burning, and the whole continent of Europe consumes it largely. It is sold by the ton of 2,240 lbs., and if £3 to £5 per ton be taken off the above quotations, producers may see at a glance the 'net profit' on consigments to Liverpool from the Southern and Western States of America."

Collodion for Photographic Purposes. — The following formula for collodion is said to have been given to a novice by a noted photographer in New York: —

"Ether, ... 6 ounces.
Some brains.
Alcohol, ... 6 "
Some more brains.
Cotton, ... 72 grains.
Some iodide.
A little more brains.
Some bromides and a large quantity of brains.
After the above is all dissolved and settled, add enough brains to make good negatives."

"Faced" Tea. — The detection and examination of the facing is simple, as its presence may be at once ascertained, by either examining the tea with a magnifying lens, or by simply washing it off by agitation with cold water. The determination of its nature after removal is accomplished by the usual processes of qualitative analysis, into which it is not our province in these popular articles to enter. We may, however, indicate the manner of detecting Prussian blue, because this "facing" is at once the most dangerous, and yet very easy to discover. Let the green tea be violently shaken up in a little bottle with some cold water, and the resulting fluid quickly poured into a wine-glass to settle. The blue powder thus detached from the tea will subside, and the water having been carefully poured off, it will remain at the bottom of the glass. If a few drops of strong solution of washing soda be now added to the powder, it will change from blue to dirty brown, thus indicating the presence of Prussian blue. — *Food Journal.*

Another Submarine Tunnel. — An engineer in the employ of the Turkish government has planned a railway tunnel made in sections, to be submerged thirty-four feet below the surface of the water, and moored to the bottom by chain cables. He proposes to sink it across the Bosphorus, and thus connect Europe and Asia by railway.

The *Ironmonger*, a prominent organ of English industrial interests, says: "A company has been projected at Birmingham for the purpose of manufacturing screws by means of new and improved machinery which has been recently introduced from the United States, and which is believed to produce a better article, at a lower price, than any machinery in use in Great Britain."

The French and Dutch were the first to use blast furnaces; they were about 10 ft. high, charged with ore and coal at the top in alternate layers. The blast was introduced at the bottom. The exact time of their invention is not known; subsequently blast furnaces were built 25 ft. high on the Rhine. At these furnaces cannon were cast in one piece and stoves made, in the fifteenth century.

Agriculture.

MINERAL FERTILIZERS.

A CLERGYMAN in New Hampshire has written ıs a letter calling attention to the "Stevens Mineral Fertilizer," which is produced in the town of Lisbon. We have heard of the "*Grafton* Mineral Fertilizer," but were in ignorance of the fact that Lisbon had commenced to grind her barren silicious rocks also, and offer them as fertilizers. It appears that Lisbon is now fairly pitted against Grafton, and in the contest it will be interesting to learn whether the *silex* of the former or the *dolomite* of the latter shall come out ahead. The parties have of course rushed to the chemists, to procure "analysis" and indorsement of their rocks; and they claim to have secured both, and are now ready to "fill orders." We give the analysis of these fertilizers, for which we make no charge.

GRAFTON MINERAL FERTILIZER.

Silica	30.30
Protoxide of iron	6.27
Lime	20.60
Magnesia	11.17
Carbonic acid	32.11
	100.45.

LISBON, OR STEVENS MINERAL FERTILIZER.

Silica	90.60
Lime	3.27
Oxide of iron	3.06
Alumina	.31
Magnesia	.38
Carbonic acid	1.35
Water	1.06
Alkalies	a trace.

Good solid plant food truly! It would be as unreasonable for a baby to turn away from a set of cast iron, as for the grasses and cereal plants to reject such delectable nutriment as is here afforded.

Our correspondent's zeal is all enlisted in favor of the silica of the Lisbon mountains. He writes as follows: "Perhaps you will be glad to know that God has prepared just such an agricultural desideratum as a *pure fertilizer*. It has been found on the Gardner Mountain during the past season," etc. In this connection we would remark that it is pleasant to know that the Supreme Being has not been partial in his favors, for there are a great many *banks* of just such *pure* fertilizers scattered all over New England. We have not been forgotten; for directly in the centre of our farm we have a deposit of this "fertilizer," from which we have taken 500 horse-loads, to cover a peat bog. It is most excellent for low, swampy lands, bringing in the rich upland grasses, when a little ashes and bone dust are mixed with it. Our deposit is a little richer in silica (sand) than the Stevens or Lisbon fertilizer. Upon analysis we find ours to give 93 per cent.; the Stevens only 90. Our price for the fertilizer taken at the farm is 25 cents a horse-load. We have not learned what the price of the Stevens article is, but have no doubt that it is *much higher*.

Our correspondent continues: "The effects of this fertilizer upon the products of the garden and field are almost *incredible*. On trees it has wrought marvelous changes, which are seen in the change of *complexion*," etc. If trees in New Hampshire have *complexions* which need improving, why not try the "Balm of a Thousand Flowers," or "Phalon's Cosmetic," and compare the effects with the Stevens fertilizer? He closes as follows: "May I ask you to visit Lisbon, and see the remarkable effects of the fertilizer yourself?" Thank you; the season of the year is rather unfavorable for visiting farms and examining crops, and besides, it is quite unnecessary, as our mind is fully made up as regards the *merits* of the fertilizer.

But enough. Ridicule is the readiest weapon with which to combat such nonsense as this, but there is a serious side to the business. It is evident that there are parties who are intent upon inducing farmers to purchase a powder, alleged to possess fertilizing properties of a high order, which is made up of 90 *per cent. of sand* and 10 per cent. of other almost valueless substances. A long article appears in the *N. H. Telegraph*, in which a specious and artful attempt is made to convince farmers that this silicious powder has a real money value, and that it is something worthy of being bought, at a price probably of 15 or 20 dollars a ton. Prof. Seely's name is used, also Dr. Jackson's and those of some other chemists, in a way seemingly to recommend the powder, but they do not in fact do this. They *dare* not do it. As a protection against such schemes, farmers everywhere should remember that the geology of New Hampshire and of the other New England States affords not the least ground for hope that any rocks (save gypsum) or deposits exist which can possibly have any considerable commercial value as plant fertilizers. Rocks and deposits, to have value worthy of attention, must hold either the phosphatic nodules or potash in some available form. The carbonates of lime and magnesia, or the magnesian and common limestone, have some value; but they are not fertilizers to be bagged or boxed up, and sent off to be sold in the market, as are the concentrated compounds holding phosphoric acid and the alkalies; neither is *silica*, which is usually the largest constituent in the soils found upon every farm. We think well of the New Hampshire rocks for building bridges and abutments; but for soil fertilization we prefer to employ something better suited to the wants of plants.

THE SUPERPHOSPHATES.

AT the meeting of the State Board of Agriculture at Framingham, in December, a lively and interesting discussion arose upon the subject of commercial fertilizers. What is known in this section as "Bradley's Superphosphate" came in for a full share of comment and criticism, and there was a free expression of views regarding the compound. Hon. Simon Brown remarked that he had learned that what was called "sugar-house waste" was largely consumed by the manufacturer, and also vast quantities of "fish pomace" were carted to his factory. The inference drawn from these facts was, that the compound contained other and cheaper materials than should be found in a true superphosphate of lime. Mr. Brown further observed that the "waste" from the sugar-house was alleged to be of trifling value, and therefore unsuited to become an ingredient in an expensive fertilizer. Mr. Brown's remarks were liable to be misunderstood, although he was quite right in his meaning; and we should have ventured upon some explanations, but exhaustion from a talk of quite two hours' continuance compelled us to leave the hall. President Clark, of the Agricultural College, however, continued the discussion, and stated, as we were informed, that the article known as "sugar-house waste" was carbonized bone, and a fertilizing substance of much value; also that fish pomace was an excellent plant stimulant, and one largely employed. We regret that we did not hear his remarks; but we have no doubt they were perfectly in accordance with facts and the deductions of science. Still, whilst the two speakers were perfectly correct in their statements, there were some important points overlooked in the discussion, which, when understood, serve to clear up what possibly might appear to some as a conflict of statement and opinion. Sugar-house waste is composed of materials derived from sugar refining, other than the bone coal used for decolorizing syrups. This rejected coal is submitted to the action of heat, and the charring process is renewed, when from use the pores become filled with impurities, and it is then fitted again to serve as a decolorizer. The amount of bone coal ultimately rendered worthless by repeated charring is considerable; and undoubtedly this, with the organic filth removed from dark sugars, constitutes "sugar-house waste;" and this is what Mr. Brown was told by the refiners was of but "little value," and all of it went to the "superphosphate" maker. We know that good dry fish pomace is a manurial agent worth about $20 the ton. The price in the market in large quantities is sometimes as low as $15 the ton. Now, the superphosphate maker alluded to may employ both of these articles in compounding his mixture, as intimated by Mr. Brown, and the ingredients, as stated by President Clark, are not worthless; but the important point is, *what is the mixture worth? what is its actual value?* That is what farmers wish to know. Has it a fertilizing value of $60 the ton, or only of 20, 30, or 40 dollars? Farmers do not care what fertilizing substances a manufacturer employs, or where he procures them, or how cheap he may be able to buy them. They are willing to pay a fair profit to the maker for any concentrated assimilable plant food that he may be able to compound; but they *do want to know* the exact character of the substances they are solicited to buy, and also their exact commercial and farm value. If a manufacturer can buy sugar-house waste at one quarter of a cent a pound which is actually worth two cents, he is driving a sharp trade, and is entitled to the benefit of his shrewdness. A fertilizer worth 50 or 60 dollars a ton cannot be made from fish pomace and sugar-house waste, and this was the idea intended to be conveyed by Mr. Brown. We have yet to find in the market a "superphosphate," or any other manufactured fertilizer, that we would purchase for farm employment at any cost approaching that sum.

ADDRESS UPON MANURES.

WE have received many letters requesting copies of our address upon "Manures Special and General," delivered before the Massachusetts State Board of Agriculture at Framingham, in December. In reply to our correspondents, we would say that the address will appear in the State Agricultural Report, to be published in March. We shall probably have a hundred copies or so printed separate from the Report, which we shall be happy to send to our friends when they are ready. If the demand increases, it is possible

we may issue an edition of one thousand, copies of which will be sent, postpaid, on receipt of *twenty cents* for each copy. We will send a copy *free* to any one who will send us a new subscriber to the JOURNAL, with one dollar.

The *Boston Cultivator*, one of the oldest and best of our agricultural journals, remarks upon the address as follows: —

"Dr. Nichols's lecture at the meeting of the Board should be heard before every enterprising farmers' club in New England. It was the most profitable address we have ever heard at the meetings of the Board."

Hon. Marshall P. Wilder, the distinguished horticulturist, was pleased to remark that "the address was the most practical and useful one which had been delivered before the Board since his connection with it, a period of sixteen years;" and President Clark of the Massachusetts Agricultural College, Hon. Simon Brown, and many other distinguished gentlemen, bestowed upon it the warmest commendation in the debate which followed its delivery. We are pleased to have presented anything which meets with the approval of the true friends of agricultural progress and are fully rewarded for our labor.

BEET CULTURE FOR THE SOUTH.

OUR much esteemed contemporary, the *Rural Carolinian*, strongly advises the farmers of the South to introduce the culture of the sugar beet. Two crops a year can be raised, and instead of impoverishing the land, like sorghum, imphee, and other sugar plants, it will greatly increase its fertility, as well as its capacity for stock raising. The soil and climate in many parts of the region are precisely adapted to this line of cultivation. Capital is required for establishing sugar factories with the proper machinery; but it is believed that this would readily be attracted by an enterprise promising such rich returns. The writer gives the following facts in regard to the recent progress of beet culture in France: —

"The prize of Argenteuil of twenty-four hundred dollars ($2,400) for the most useful invention during the last five years in France, has been awarded to Mr. Champonnois, the inventor of the distillation of alcohol from the beet root. Some idea of the importance of his discovery may be obtained by comparing the following figures: Before the alcohol was distilled from the beet root, 4,867 acres of land, carrying this crop, were under cultivation, the proportion of wheat grown to the acre on this land being fifty-three bushels; the number of cattle supported being 25,386 head; the number of cattle fattened being 6,955 head; and the number of workers employed being 16,618. Since Mr. Champonnois' discovery, the number of acres of land devoted to the cultivation of beet root, divided into five hundred farms, has increased to 53,512 acres; the yield of wheat per acre, to seventy-four bushels; head of cattle supported, to 51,449; head of cattle fattened, to 46,656; number of workers employed, to 40,453. 735,000 tons of beet root, yielding 6,468,000 gallons of alcohol, at the average rate of two francs and twenty-five centimes per gallon, produce a gross annual income of $2,911,000."

"The northern part of France was, at no very remote period, the least remunerative portion of the empire. The average production of wheat was about twelve bushels to the acre; the product now averages about forty-five bushels, and that region supports large herds of cattle, unsurpassed in size and quality, with corresponding amelioration in the condition of the population. This revolution has been effected through science, by the culture of the beet; and the manufacture of sugar from that 'providence,' to use the words of her distinguished statesman, Monsieur Thiers, 'the beet, has at three separate periods saved the empire.'"

HOW TO MAKE FARM LIFE ATTRACTIVE.

1. BY less hard work. Farmers often undertake more than they can do well, and consequently work too early and too late.

2. By more system. The farmers should have a time to begin and stop labor. They should put more mind and machinery into their work. They should theorize as well as practice, and let both go together. Farming is healthy, moral, and respectable; and, in the long run, may be made profitable. The farmer should keep good stock, and out of debt.

3. By taking care of health. Farmers have a healthy variety of exercise, but too often neglect cleanliness, eat irregularly and hurriedly, sleep in ill-ventilated apartments, and expose themselves needlessly to cold.

4. By adorning the home. Books, papers, pictures, music, and reading should all be brought to bear upon the in-door family entertainments; and neatness and comfort, order, shrubbery, flowers and fruits should harmonize all without. There would be fewer desertions of old homesteads if pains were taken to make them agreeable. Ease, order, health, and beauty are compatible with farm life, and were ordained to go with it.

FARMERS' MEETING IN NEW HAMPSHIRE. — The State Agricultural Society of New Hampshire will hold a convention at Manchester, commencing Tuesday, January 24, and continuing three days. We have accepted an invitation to deliver an address on the second day, or Wednesday the 25th inst., and shall endeavor to discuss some topic of practical importance to husbandmen. Some of the best farmers and horticulturists of the State and of New England will be present and take part in the proceedings. The meeting will undoubtedly be full of interest, and we hope our farmer patrons will be present.

VARIETY OF FOOD FOR THE HOG. — In an experiment detailed in *Deitz's Farm Journal*, where hogs were fed on cooked potatoes and oats, the excrement showed by the iodine test that a large portion of starch was passing off undigested. The addition of a small amount of peas to the feed caused all the starch to be appropriated to the animal economy. Experience has demonstrated that a variety of food is essential to the perfect development of animals. When hogs are fed for any length of time on the same food, they become "glutted," and the addition of even a single article of food to their accustomed diet causes a marked improvement. If they are fed on corn, they should have pumpkins or potatoes; access to grass should be allowed them when they do not have a variety of food.

TO PROPAGATE JAPANESE LILIES. — The *Vermont Farmer*, a promising agricultural journal, just started at Newport in that State, gives the following hints concerning the propagation of Japanese lilies, which are as hardy as they are beautiful, and ought to be more generally cultivated: —

"If one has a bulb or two to start with, the stock may be readily increased. If left to themselves, the bulbs become large clumps by natural subdivision, but this is a slow way of multiplying them. If a lily be taken up in autumn, after the leaves have withered, there will be found upon the stem, just above the old bulb, a mass of small bulbs intermingled with roots. A dozen, and even more, are frequently found. The little bulbs may be removed and planted out separately, or the stem to which they are attached may be cut off just above the old bulb, and set out with the cluster of bulbs and roots attached. They should be covered the first winter with a few inches of litter. The next season they will make strong bulbs."

A LARGE PEAR. — A friend has shown us a California pear of almost incredible size. It measures around, 13½ inches, and lengthwise, 17½ inches. It is now somewhat shriveled, but it was said to weigh *three pounds* when taken from the tree. The variety we judge to be the Vicar of Winkfield although not quite certain. These pomological monstrosities are not uncommon on the Pacific coast, but to us they seem wonderful. We should be careful in venturing under trees loaded with such fruit, as the effect of the blow resulting from the fall of a specimen might prove decidedly unpleasant.

PINE-TREES THEIR OWN INCENDIARIES. — A French writer thinks that the very frequent fires which occur in pine forests in summer, far from any habitation, are not due, as has been commonly believed, to careless or mischievous people, but to the action of the sun's rays concentrated by the globules of resin which exude from the trees. These act as burning lenses, and start the conflagration, which of course, spreads rapidly among such inflammable material.

RAG PULP IN BUTTER. — After melting a sample of butter purchased at Brixton, a large clot separated, and although the sample was left all night in a cool place, it did not again solidify. This led to an immediate microscopic examination, and proved beyond a doubt that rags in a state of pulp had been employed in large quantity. The rags themselves conjure up ideas sufficiently nauseous; but, in addition, *the dyes had not even been discharged*, as the filaments presented a great variety of magenta, blue, brown, and other colors. — *Food Journal.*

STEAMING FOOD FOR CATTLE. — The *Practical Farmer*, in an article on this subject, makes the very sensible suggestion that galvanized iron pipe should not be used in the apparatus, as the zinc coating is liable to scale off and poison the food with which it becomes mixed. It would appear that in some cases cattle have actually been poisoned in that way. These dangerous pipes should under no circumstances be used in conveying water for either man or beast, or in any process connected with the preparation of their food or drink.

BIG VINES AT THE SOUTH. — The "Walter Raleigh vine," on Roanoke Island, nearly three hundred years old, covers one acre of ground; the wine from this vine last year sold for $3,000; another vine in Tyrrel County, N. C., in 1869, produced 2 530 gallons of wine; several other large vines in the South produce each from 1,000 to 2,000 gallons of wine per annum.

COTTON-SEED FOR SMYNRA. — A new branch of commerce has just been opened between this country and the southern part of Europe and Asia. An invoice of forty-five tons cotton-seed was recently shipped from New York to Smyrna for the purpose of planting, the object being to start the raising of cotton in these sections from American seed.

☞ WE would call the attention of our farmer friends to the agricultural journals offered in our clubbing list.

Boston Journal of Chemistry.

Jas. R. Nichols, M. D., *Editor.*
Wm. J. Rolfe, A. M., *Associate Editor.*

BOSTON, FEBRUARY 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

ZINC POISONING.

GALVANIZED IRON WATER-PIPES.

No source of danger to the public health, that we have detected, and pointed out in the Journal, has awakened greater interest, or provoked more opposition and controversy, than our statements regarding the dangerous nature of galvanized iron water-pipes. Before we called attention to this alarming source of danger, no physician, chemist, or journal of any kind in this country, so far as we can learn, had ever alluded to the matter, or manifested any suspicion of peril. This apparent neglect or indifference arose probably in part from the circumstance that the galvanized pipe had come into use for water conduction so rapidly and quietly that it was not generally known, among those competent to judge of its character, that it was being extensively employed; and also a popular idea has prevailed, and unfortunately still prevails to some extent, that the salts of zinc are not specially poisonous to the human system. Where or how this idea originated, it is difficult to understand. The exact character of the zinc compounds, it is true, has not been carefully and properly investigated; and therefore we find in books but little regarding their nature as toxicological agents. From experiments and observations made during the past six months, and from a knowledge of some of the sad instances of poisoning which have occurred in this vicinity, we have no hesitation in declaring that zinc is at least as virulent and fatal a poison as lead. We think it quite possible or probable that it may be proved to be even *more dangerous* than lead. In small quantities it produces nausea, in larger it produces vomiting with violent retching and great cerebral distress. The chloride is the most active in its effects, and numerous instances of poisoning from its use have been recorded. Those engaged extensively in Burnetizing timber (a process by which wood is impregnated with chloride of zinc in solution) suffer from zinc poisoning; and the symptoms are strikingly like those of lead poisoning. Instances are recorded of poisoning from the use of chloride of zinc as a disinfectant. More of these have occurred in England than in this country, as the liquid is largely employed there. The chlorides are not often found in water passing through galvanized iron pipes. The protoxide and carbonate of zinc prevail in these waters. Fifteen grains of the protoxide, given daily to a dog, soon made the animal ill, *and killed it in less than a week.* Painters who use, and manufacturers who make oxide of zinc suffer from its poisonous effects. It produces a colic resembling that caused by lead, and which is known as *zinc colic.* We have ascertained that some painters are so sensitive to zinc poison that they will not use it. Those who are not affected by lead suffer terribly from zinc; and when attempts have been made to deceive workmen, by alleging that lead was used instead of zinc, the falsehood has been detected by the peculiar effects experienced. By far the most common compounds of zinc found in water which has passed through galvanized iron pipes are the protoxide, and the carbonate of the protoxide. These usually make their appearance in a few hours after water is first drawn from the pipes, and they continue to form so long as any zinc remains upon the interior. The manufacturers have recently contrived to make the coating of zinc quite heavy, which of course greatly enhances the danger, as it affords a longer time for the coating to be removed, and the poisoning effects are protracted. We have in several instances had brought to us, for chemical examination, a whitish powder alleged to have been taken from joints in the galvanized pipes, which we found upon analysis to be carbonate of zinc mixed with a little sesquioxide of iron. In one instance, *nearly half an ounce* of this salt was scraped from the interior of a galvanized pipe of sixty feet in extent. This powder, in minute quantities, produces exceedingly disagreeable effects upon the stomach and bowels, indeed upon the whole system. We took *half a grain* in the evening an hour before retiring, and passed a very uncomfortable night. The disturbance is not alone confined to the digestive and assimilating organs, but all the secretions become affected, and a persistent metallic taste remains for a day or two. We are led to think that this mixed carbonate of zinc, formed under peculiar circumstances in water and in the presence of organic matter, is different from *calamine*, or the impure carbonate of zinc of commerce, and a more potent poison. There is manifestly much to be learned in relation to the salts of zinc, and their effects upon the system; and we are certain future investigations will afford much light upon the subject. The recent sad case of zinc poisoning by water drawn from galvanized iron pipes, occurring in Melrose, is a warning which cannot fail of being heeded. It is not necessary for us to dwell upon it, as Dr. Smith, in another column, under the medical head, has presented a full account of the distressing case. Mr. Sargent, of the house of Sargent Bros., is one of the best known and most extensive dealers in dry goods in this city, and one of the most respected and influential citizens of Melrose.

Instances of poisoning, of greater or less severity, are not rare in this vicinity. One physician has informed us that six cases have come under his care within a few months. With these indubitable facts before us, there is reason to be thankful that we have been led to point out this new source of danger to the health of individuals and families.

Since the above was in type, our attention has been called to the report of Dr. Winsor, of Winchester, Mass., upon galvanized iron pipes, made to the East Middlesex Medical Society, and published in the *Boston Medical and Surgical Journal* of December 5th. The question that Dr. Winsor, as chairman of a committee, was appointed to report upon was this: "Does galvanized iron pipe impart any poisonous quality to water conducted through it?" We have not space for the comments upon this singular medical production which we would like to make. It may be stated in brief that the committee, after consulting Appleton's "Cyclopædia," and the *manufacturers of galvanized iron pipes*, find themselves ready to report "that there is no proof that water derives any poisonous or harmful quality from passing through galvanized iron pipes." This conclusion is reached after admitting that water freely dissolves the zinc coating, and that quantities as large as six grains of the carbonate to the gallon are often found. They state that where the joints of the pipe are screwed together, they are packed with red or white lead, and coolly remark, "*So one has a chance of drinking a little lead in their water when they begin to use galvanized pipe.*" It appears, then, that in addition to large quantities of carbonate of zinc, the water which passes through these pipes holds *lead* also, and this disgusting, poisonous, metal-impregnated water is not harmful to the men, women, and children of the households where it is used!

The writer or writers of this report assume that the carbonate of zinc is the only salt of the metal ever present in water, and that the carbonate is not poisonous. They do not appear to have any knowledge of the important chemical fact that the formation of the carbonate is dependent upon the prior production of the oxide. The oxide or protoxide of zinc is the compound first formed when water comes in contact with the metal, and this highly poisonous substance often remains unchanged when the water is used freely by families. If the committee had made a few simple chemical experiments, their report would have been essentially modified. When water is poured into a galvanized iron pipe, or when a little granulated zinc is thrown into a glass of water, decomposition of the water almost immediately commences. The oxygen of the water unites with the zinc, forming the oxide, and the hydrogen is set free. Little bubbles of this gas are seen to form upon the surface of the metal at once. Zinc is the metal commonly used to procure hydrogen for experimental purposes. If when water is added to zinc the surface did not become covered with the oxide, it would not be necessary to add sulphuric acid to produce active decomposition. The only use of the sulphuric acid is to keep the surface of the zinc clear of the oxide, which it does by converting it into a sulphate. Water acts with great energy upon zinc when a clean surface is presented to it. The oxide is, then, *first formed* in the pipes, and held in the water, unless there is carbonic acid enough present to change it into a carbonate. This is by no

means always or usually the case. The oxide that falls off from the surface of the zinc-covered pipe, and is precipitated to the bottom, remains long enough in the pipe to be converted into the carbonate. But much is held in suspension, and passes as unchanged oxide into households to be employed in food and drinks. The idea that the carbonate is the only compound of zinc found in the water passing through galvanized iron pipes is an error, and also it is an error to suppose that the carbonate is not poisonous. The two assumptions found in this report are unwarrantable and dangerous; and it is difficult to understand how a body of cultivated, intelligent medical gentlemen could allow the publication in their name of a report upon an important subject so ill considered as this. It supplies a capital advertising hand-bill to makers and venders of the galvanized pipe, and doubtless it will soon be published in their interests, and thus it will aid in extending a sanitary evil of no small magnitude. It should be observed here that zinc, like lead, does not affect all persons alike. It is probable that there are many who can allow considerable quantities of the salts of the metal to enter the system, and remain in apparent health. We know that lead, copper, mercury, and the other poisonous metals act in this singular way upon the human organism. It often happens that in a family using water contaminated with zinc or lead, no one apparently suffers, or perhaps one or two may sink under the poison. In Mr. Sargent's family, consisting of seven, only the children suffered severely. All, however, were affected in a sensible degree. It is usually those constitutionally weak, or of low vitality, who are prostrated, or there may be some idiosyncrasy of organization which causes metals to act with great energy as poisons. This matter is imperfectly understood at present; but so long as we *do know* that many are liable to be brought under a deadly influence when even minute quantities of zinc or lead are introduced into the system, it is our duty to guard with watchful care every avenue through which these metals may find access to the food and drinks used in families. We shall refer to this report again.

THE PEAT DELUSION.

In our daily visits to the city, we pass on the line of railway a dilapidated building, from the chimney of which, a few years ago, smoke and puffs of steam issued most vigorously, and it was evident that considerable activity prevailed within. This was a "peat manufactory;" and in front of it a vast wet bog composed of the substance stretches away in the distance. But alas, all is silent in that vicinity now, and the frogs and tadpoles of the meadow are no longer disturbed in their day slumbers, and the mosquitoes are able no longer to insert their sharp tubes into the bare arms of the peat-diggers. It is a little hazardous to mention the subject of "peat" in that neighborhood; indeed, it is a disagreeable topic to converse upon in any part of the county of Essex, and, we may say, in any part of the State. We have, however, recently seen some indication of an attempt to revive the peat excitement; and as it is now about six years since the last spasm, it may be time to try it again. New dupes turn up, ready to bite at any bait which is artfully presented, as often as twice in each decade; and it is by no means impossible that a repetition of the peat fever may occur in some sections.

There always have been, and we presume there always will be, plenty of people ready to engage in projects and speculations regarding which they know nothing, and in which they are sure of being pretty effectively fleeced. In regard to peat the idea held out is that the wet bog as found in our New England meadows can be dug out, and, by the aid of somebody's patent machine, speedily and cheaply compressed into compact, dry fuel. This is a delusion, a complete delusion. No machinery ever has been constructed, and in our view it is extremely doubtful if any can be constructed, which will transform the tenacious water-impregnated peat of our low grounds into cheap fuel. We have examined some specimens alleged to have been made by various machines, which were of tolerably compact and dry structure, and which of course burned freely and pleasantly; but we have no doubt the article cost the manufacturer at least fifty dollars a ton. We have made a sufficient number of experiments upon the peat from our own bogs to learn that it is a difficult and expensive article to manipulate, — a very unpromising material to attempt to improve by the aid of machinery or other appliances. Dry compressed peat affords upon combustion less than one half the heat afforded by anthracite coal of equal weight; and it has the disadvantages of giving off an exceedingly unpleasant odor, and leaving a huge mass of light and troublesome ash. It cannot be dug out, dried, and compressed for any sum that will bring it into competition with coal; and therefore it is perfectly preposterous to give the matter any further attention. There has been lost by victims of the peat delusion, in New England alone, nearly or quite *a million of dollars*, and this has gone into the pockets of the owners of "patent peat machines," and speculators interested in keeping up the excitement. We advise our readers to have nothing to do with any schemes for manufacturing peat, however flattering the prospects may be made to appear.

SPECTROSCOPIC RESEARCH.

Among those who are devoting themselves to scientific research in this country, there is no one who is attracting more attention at home and abroad than Prof. C. A. Young, Professor of Natural Philosophy and Astronomy in Dartmouth College. We have for several years watched the career of this gentleman with much interest; and we are certain that there are few men living who pursue science with more indefatigable, intelligent zeal than Prof. Young. He is an honor to the venerable and excellent institution with which he is connected, and to our common country. The department of science to which he is devoting special attention is connected with spectroscopic research, and recently he has devised a form of spectroscope which embraces some new principles of the highest importance to science. In the construction of this instrument he had the aid of those distinguished American opticians, Messrs. Alvan Clark & Sons, of Cambridge. The instrument has the dispersive powers of thirteen prisms, and, even with a low magnifying power of only five on the observing telescope, shows perfectly the lines of aqueous vapor which make their appearance between the sodium lines when the sun is near the horizon. Everything shown on the maps of Kirchhoff and Angström is readily seen, and many lines beside. During the months of September and October, Prof. Young carefully examined many sun spots with the new spectroscope, using it in connection with the small 6-inch telescope of the Dartmouth observatory; and also the wonderful solar protuberances, concerning which, at the present time, so much interest is felt, have been repeatedly examined. These consist of vast clouds of luminous matter which are projected with inconceivable force beyond the sun's disk, away into space. Some of these columns of flame, 30,000 miles in height, have been examined throughout their whole extent, and the new instrument reveals the most delicate details with great beauty and clearness. The workmanship is so exquisite that this is accomplished although the light, in passing through, is reflected or refracted by 43 different glass surfaces. The flame clouds move with immense velocity; one of those examined was flying at the rate of 120,000 miles per second, and the space it passed over was more than 90,000 miles. One of the most interesting of Prof. Young's discoveries is that of a brilliant cloud of flame *upon the sun's disk*. These bright clouds have seldom been observed when projected beyond its edge; but it is now certain that they form, or break off from the great mass of flame, and float away until from some cause they are extinguished. The cloud seen and carefully examined was more than 130,000 miles long, and it was in the field of the instrument for nearly one hour. How inconceivably grand and startling are these discoveries! How sublime, how vast, are the operations of nature! The field for research is immense, and we are pleased to know that our countrymen are doing their part in the work of exploration.

A DANGEROUS FRAUD.

The following letter from Francis Lee, Esq., of Clinton, Iowa, and the reply, are published in the *Clinton Daily Herald* of December 15th: —

Clinton, Ia., *Nov.* 22d, 1870.

Messrs. Jas. R. Nichols & Co.: —

Gents., — A burning fluid designated as Danforth's Non-explosive Petroleum Fluid is being sold and introduced into dwellings and business houses by S. R. Snyder & Co., and is represented as being perfectly safe. I send you by express one of their circulars, and a sample of the fluid. Will you please examine it, and give me your opinion. Is it as represented, and perfectly safe?

Francis Lee.

Boston, *Dec. 9th*, 1870.

Mr. Francis Lee: —

Dear Sir, — The bottle holding the fluid sent to us for analysis reached our Laboratory in safety, and a portion of the contents has been subjected to chemical examination. We find it to be Coal Oil Naphtha, having a specific gravity of 7.12 and igniting at a temperature as low as 44 degrees F. This is a very dangerous fluid to use in lamps for the purpose of household illumination, and every family into which it enters is subjected to fearful danger. Any party offering for sale such a fluid for illuminating purposes in Massachusetts would be liable to fine and imprisonment, and under United States laws the offending party can be punished. Very truly yours,

James R. Nichols & Co.

The following item is taken from the *Boston Traveller* of December 28th: —

"*Killed by Non-explosive Oil.* — A girl named Mary Gibson was fatally burned at Poughkeepsie, N. Y., last evening, by the explosion of a lamp containing *Danforth's Non-explosive Oil.* She has a mother living in Providence, R. I."

Another murder from the use of naphtha, alleged to be *non-explosive* by an impudent charlatan. We have exposed this dangerous liquid a dozen times, but still there are people willing to listen to any empirical statements. If the good people of the Western and Middle States do not "crush out" this dreadful business, they deserve to be "blown up."

QUACK CHEMISTS.

UNDER this head, Prof. F. W. Clark, in the November number of *Old and New*, after alluding to some of the difficulties of chemical analysis, especially in the case of mixtures of organic compounds, goes on as follows to expose the falsehood and worthlessness of many of the "certificates" given by these chemical quacks: —

"In many cases, these certificates are given without even an attempt at analysis having been made. For example, a friend of the writer was one day in the office of a noted quack chemist in one of the New England States, when a stranger entered with a new nostrum to be analyzed. The chemist, scarcely glancing at the substance, asked its proprietor what it contained, and received a list of ingredients in reply. Then, depending solely upon the word of the stranger (quacks are proverbially truthful), a *certificate of analysis* was made out, paid for, and the fellow went on his way rejoicing. The guilty chemist in this case has attained to some celebrity, and by the outer world is regarded as a high authority. This sort of thing happens every day; and many of the certificates printed upon the labels of proprietary medicines are of this character, and not worth the paper upon which they were first written.

"These certificates, however, vary in form, the absolute lie being probably rare. A favorite style among those quack chemists who fondly imagine themselves possessed of consciences runs somewhat as follows: This is to certify that I have *examined* Mr. Smith's, Brown's, Jones's, or Robinson's (as the case may be) elixir, panacea, spirit, oil, or balm of a thousand humbugs (as the case may be), and find in it nothing of a deleterious character. The whole is wound up with a glowing panegyric (the degree of enthusiasm being measured by the amount of the fee received) upon the wonderful properties and virtues of the nostrum in question. Now, the analytical part of this is literally true in most cases. The substance is examined, — the chemist looks at it, smells of it, and, if he is very courageous, tastes of it; and nothing injurious, in fact nothing whatever, is found. But the certificate is intended to convey the idea of analysis, and therefore is to all intents and purposes a lie. In fact, it is worse than a lie; for to the crime of deception is added the disgrace of cowardice and hypocrisy. The truth is used as a mask for the falsehood.

"Many certificates, however, are given, which merely state that the nostrum examined is free from lead, mercury, silver, iron, or other metallic ingredients. These substances being easily detected, there is nothing necessarily false in such a certificate; and the value of the latter then depends wholly upon the character of the chemist giving it. It is to be hoped that they are usually true. But, notwithstanding these exceptional cases, the great majority of quacks' chemical certificates are absolutely worthless.

"It is hard to overestimate the harm done by this scientific swindling. Many of the most widely advertised 'remedies' are pernicious, not to say poisonous; and oftentimes serious illness, sometimes death, results from their use. . . .

"At present, thoroughly educated, reliable chemists are loath to undertake 'job-work' of any kind, preferring rather to obtain permanent situations as professors, superintendents of chemical works, or managers of assay-offices. They dare not give false certificates, or such as would be available to the venders of patent medicines; nor will they even run the risk of being confounded professionally with their disreputable (half) brethren.

"But it is not only in the analysis of unanalyzable nostrums that chemical quackery is evident; the same lack of conscience is manifest in other kinds of work. The mining company whose mines are deficient in metal wish a better certificate than truth will allow, and straightway the quack chemist finds for them as much of the precious material as they desire in their ores. The most worthless minerals are found to be rich in everything, and a hundred per cent. of gold from pure quartz is quoted on the prospectus of the mine. . . .

"But perhaps the most glaring examples of scientific criminality may be found in the recommendation given by some chemists for dangerous and explosive naphthas and petroleums. Here is a case in point. A dealer carried a sample of a patent oil or burning-fluid to a well-known Massachusetts chemist, desiring a good recommendation, whereby he might secure better sales. The fluid was so inflammable that its vapor would ignite from a lamp placed ten feet from the bottle; and yet the chemist recommended it as an excellent article, much less explosive than other similar products which he had examined. Possibly the latter part of the assertion may have been true; but the bare recommendation of so dangerous an article was criminal."

EDITORIAL NOTES.

CHEMICAL NOMENCLATURE. — We have seen the following item in several of our medical exchanges: —

"*A Chemical Expert not Expert.* — A chemist who was examined as an expert in a recent trial in a San Francisco court, spoke of 'Chlorate of Potassium' and 'Carbonate of Sodium,' and described the former as composed of chloric acid and potassium — at least he is so reported in the papers."

It is the critic who is not an expert in the rival forms of chemical nomenclature to be found in recent books. In Miller's great work on Chemistry you will find all the names of ternary salts after the above pattern; and, on the face of it, "sulphate of *potassium*" is as appropriate as "sulphate of *iron*." The question at the present time, however, appears to be between such forms as "*potassic* sulphate" and "*potassium* sulphate;" of which *we* prefer the former.

INFLUENCE OF DIET ON THE COMPOSITION OF BONE. — Some very interesting experiments have been made by M. Papillon, and communicated to the French Academy. He fed pigeons and rats with food containing small quantities of phosphate of strontia, phosphate of magnesia, and phosphate of alumina. These substances were given daily in small doses for several months without any visible effect on the health of the animals. On analyzing the bones of the pigeons that had been fed with the strontia, there were found in a hundred parts of the ash of the bones: —

Lime	46.75
Strontia	8.45
Phosphoric acid	41.80
Phosphate of magnesia	1.80
Residue	1.10
	99.90

The ash of the bones of the rats that were fed with the alumina gave: —

Lime	41.10
Alumina	6.95
Phosphoric acid, &c.	51.95
	100.00

while in the bones of those fed with the magnesia were found: —

Lime	46.15
Magnesia	3.56
Phosphoric acid, &c.	50.29
	100.00

It is very remarkable that strontia, magnesia, and alumina can be made to enter into the composition of bone by means of an appropriate diet. A fact of this kind is calculated to raise our hopes of the possibility of modifying the animal body by means of medicines. Possibly ossification of the arteries might be stopped by an appropriate diet.

CATS' MEAT IN LONDON. — It is stated, on good authority, that from 900 to 1,000 horses, averaging two hundred weight of meat each, are boiled down every week, and sold as food for the cats and dogs of the British metropolis. These 200,000 pounds of meat are sold at an average price of about five cents a pound; so that the trade amounts to $10,000 a week, or more than *half a million of dollars* a year. At least a thousand persons are occupied as carriers or sellers of this provision for the feline and canine population of the great city.

ON GRINDING COFFEE. — A London paper says that the Germans have lately found that it is not economical to use coffee ground so coarse as is common; if ground fine, one half the quantity will make equally good coffee; and if pounded in a mortar till reduced to an impalpable powder like flour, as practiced in Turkey and other Eastern countries, still less, only two fifths, is needed. Further experiments went to show that the result was the same whether the beverage be prepared by simply pouring boiling water over the coffee and letting it stand a short time to draw, like tea, or if the infusion be allowed to boil up once or twice, or the coffee simply filtrated. But it was abundantly proved that by the last-named mode of proceeding, though the strength of the coffee remained the same, the aroma was preserved to a much greater extent than by either of the other methods.

On the other hand, the *Food Journal*, which is unexceptionable authority on all culinary matters, says that if coffee be ground very fine, there is a decided loss of aroma in the infusion. It commends the coffee prepared by the French Coffee Company for the coarseness of the grinding.

If the coffee is kept for any length of time after being ground, we are inclined to think that this latter view is correct; but if it is ground at home just before being used, we should rather side with the Germans.

ATOMS.

THERE has been a case of hydrophobia in England caused by the bite of a donkey, but it is thought that the animal must have been previously bitten by a mad dog. — Leaves of fresh wintergreen scattered where red ants congregate will disperse them as effectually as camphor. — A railway, twelve hundred miles long, is to be built in Siberia; the greater part of it extending through desert regions covered with ice and snow for ten months of the year. — In the French army more than thirty per cent. of the conscripts can neither read nor write; in the Prussian army, only four per cent. — A cheese factory, of two-thousand-cow capacity, is building in Minnesota. — Much of the "jujube paste" sold in the shops is made of glue and molasses, or the same composition as is used for printers' rollers. — In England there are sixty-five persons to each acre of potatoes; in France, thirteen; In Ireland, five and

a half. — The State Medical Society of Ohio has asked the Legislature to make it a penal offense for any one except a regular physician to perform vaccination. — A fine work on European Spiders has just been issued at Upsala. Singularly enough, it is printed in English. — Three tons of coal represent the labor power of a man for his life-time. — The Prussian Government has already given orders for 200,000 wooden legs. — The frequent explosions of nitro-glycerine nowadays suggest the necessity of more stringent laws concerning the manufacture, storage, and transportation of the dangerous compound. — Colorado built about three hundred miles of railroad in the last nine months of 1870, which is no mean achievement for a territory whose population numbers only 75,000. — Soluble glass is coming into use in Europe for "waxing" floors, and is found to answer the purpose admirably. — The *Manufacturer's Review*, of New York, claims to be "the only paper in the English language, devoted to the technical aspects of textile manufacture and dyeing;" but even without the stimulus of competition in its special field, it is as excellent as it is cheap. — It is said that "the heathen Chinee," in his native land, has life insurance companies three thousand years old, and marine insurance companies dating back to antediluvian times. — We see "Montauban's Patent Prepared Tragacanth" advertised in the *Food Journal* as "an adjunct to the breakfast and luncheon table, valuable to both the robust and the weak in health." — From the Paris correspondent of the same journal for January, we learn that "some gastronomical philosophers of the Acclimatization Society have been banqueting on all the extraordinary viands which they could collect, and *salmi* of rat and broiled dog's liver are declared by them to be exquisite, while the young rats which furnished the garnish to a roast cat were admitted to be uneatable, and a dog's hind-leg was pronounced as tough and stringy as it is proverbially crooked." — Of seventy samples of petroleum oils tested by the Board of Health in New Orleans, *thirty-seven* were dangerous, nine of the number burning at a temperature *below* 32° F. — The New York *Medical Gazette* warmly commends *Zell's Popular Encyclopœdia*, which, by the by, will be completed in fifty-five numbers, the last five of which are furnished gratuitously to subscribers. Baron Haussman is said to have spent about 425 millions of dollars in Paris during his rule; but it must be admitted that the improvements made in the city are worth a good part of the money, if not the whole of it. — A paragraph is "going the rounds" to the effect that "the largest room in the world," is in a Rhode Island cotton-mill, the said room being 750 feet long by 76 wide; while, we may add, the main hall of the Crystal Palace at Sydenham is only about 1,600 feet long and 380 wide. — Another migratory item states that the Croton aqueduct is the largest in the world; but the aqueduct which brings the water of the Yonne to Paris is some ninety miles long (an American scientific journal says 140 miles, apparently confounding kilometres with miles), or more than double the length of that which supplies the wise men of Gotham. — A medical exchange says that the student who translated *tempus fugit* into "few get time" was clever in his Latin compared with most doctors and druggists. — The question whether aniline colors are poisonous appears to have been settled thus: they are never poisonous when pure, but they are so rarely pure that the safest rule is to consider them as *always* poisonous. — The price of the *Technologist* has been advanced to *three dollars* a year, but it is cheap enough at that, especially when taken in connection with the BOSTON JOURNAL OF CHEMISTRY. — The *American Chemist* promises to be a success financially, as it unquestionably is every other way. — Be sure to read our clubbing list and premium list, which you will find in our advertising columns.

LITERARY NOTES.

MESSRS. HURD AND HOUGHTON have published *Suburban Sketches*, by W. D. Howells; a series of papers in the author's best vein. It is one of the pleasantest books of the season, and we wish we had room to speak of it more at length.

The same publishers have issued a new uniform edition of Cozzens's Works. In the volume which chronicles *The Sayings of Dr. Bushwhacker*, among other good things are some capital papers in the "familiar science" way, like the "Journey around a Tapioca Pudding," "The Radiant Dinner Castor," "A Peep into a Salad Bowl," etc.

Want of space forbids us to enlarge upon these genial volumes, or to make more than a passing reference to Appleton's cheap reprint of Huxley's *Lay Sermons and Addresses;* the bound volume of *Good Health* for 1870, which we heartily commend to all who have not read it in its monthly instalments; and Rolfe's edition of *The Merchant of Venice*, which *Harper's Magazine* thinks "will prove not only useful as a school-book, but a favorite as well in the parlor." Other books and pamphlets on our table must lie over to another month without even this "mere mention."

THE NEW CATTLE DISEASE. — The farmers and cattle breeders of New England are greatly alarmed at the appearance of the new disease in their herds, affecting the mouth and hoofs of the animals, a disease exceedingly disgusting and inconvenient, but not very fatal. In this country we have been singularly successful in "stamping out" cattle plagues, and we do not feel particularly alarmed in view of the appearance of the new one. We shall soon conquer it, as the usual energetic measures are being taken for its suppression. We employ in our barns *carbolate of lime* as a preventive or disinfectant. It is very effective and not costly. A handful or two thrown around the cattle stalls every morning and night will serve to destroy contagion, and it will in no way injure animals. J. R. Nichols & Co., Chemists, 150 Congress St., can supply the carbolate of lime in any quantity. The solution of carbolic acid is excellent to apply to the hoofs of affected animals.

☞ SINCE the last number of the JOURNAL was issued, large accessions to our subscription list have been made, many of the new patrons residing in distant lands. We have new subscribers from Para, in Brazil, and from Rio Janeiro, and not long since a fine list was sent us from Melbourne, Australia. From a single town in Tennessee we have received *eighty new subscribers*, and all parts of the South are giving us a most generous support. Thanks, friends, your kindness is fully appreciated.

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

THE *American Journal of Science and Arts* (Silliman and Dana's), for January (the first number of the monthly issue), contains articles on the Quaternary or Post-tertiary of the New Haven Region, by Prof. Dana; on the Solar Corona, by Prof. Norton; on the Duration of Flashes of Lightning, by O. N. Rood; on the Electro-tonic State, by A. M. Mayer; on Some Phenomena of Binocular Vision, by J. Le Conte; on the Earthquake of October 20, by Prof. Twining, etc., etc.; with the usual valuable summaries of scientific intelligence, etc.

The *New York Medical Journal* has the following Original Communications: I. Fordyce Barker, M. D. — Blood-letting as a Therapeutic Resource in Obstetric Medicine; II. Albert H. Buck, M. D., and Francis Delafield, M. D. — Abstract of Virchow's Lectures on Morbid Tumors; III. J. H. Hobart Burge, M. D. — A Sexless Child; IV. John H. Packard, M. D. — Notes on Hæmorrhoids; V. J. C. Nott, M. D. — Carbolic Acid as a Remedy for Carbuncle; with Proceedings of Societies, Reports on the Progress of Medicine, etc.

The leading articles in the *Chicago Medical Journal* are, I. Cavernous Tumor of the Orbit, complicated with a large Sanguineous Cyst: Successful Removal without Injury to the Globe or Optic Nerve, by E. L. Holmes, M. D.; II. Chronic Pemphigus, by Walter Hay, M. D.; III. Cook Co. Hospital Clinic, by C. T. Fenn, M. D.; IV. Hydrate Chloral, by S. W. Gould, M. D.; V. Trismus Nascentium, by Theo. W. Stull, M. D.; VI. Case of Imperforate Anus, etc., by Moses Barret M. D.; VII. Cases in Private Practice, by Jno. E. Owen M. D. There is the usual interesting variety of Selections, Re views, Medical Items, News, and Gossip, etc.

Most of the medical journals for January have not come t hand before we go to press (Jan. 16).

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — hom science, arts, agriculture, medicine, etc. — will be answered unde this head, but *only when the subject is one of general interest to ou readers.*

VICTIM, of TITUSVILLE, PA., and all others must remembe that we do not answer any inquiry in this department of th JOURNAL unless we have the true and full name of the corre spondent.

H. A., BEAVER, PA. Perhaps soluble silicate of potassa, o marine glue, will serve to attach glass labels to bottles, so tha they will remain unaffected by water or acids.

W. J. H., MESOPOTAMIA, OHIO. It is quite in accordanc with the practice of our best physicians to combine opium wit belladonna, and we see no incompatability in the association.

C. J., TROY, N. Y. Hair dyes containing nitrate of silve should be kept in a dark place to prevent change. Light pro motes chemical decomposition, and the solution is spoiled.

C. B. P., CHAUMONT, N. Y. Fish specimens can be pre served in alcohol or in a weak aqueous solution of carbolic acid Glycerine is also a good preservative agent, if the specimens ar not to be kept for a long time.

B. C. S., CENTRE, ALA. To kill animals with strychnine the pure alkaloid in crystals should be used. A few grains (thre or four) will almost immediately destroy life in a fox or a dog.

I. T. S., SALEM, MASS. But little good could result fro any statute laws against medical quackery. We must rely upo the intelligence of the people for the doing away of the evil. I the people can be educated and made acquainted with the gen eral principles of the natural and physical sciences, they will dis card quacks and quackery, and the business will soon end.

F. B., BOSTON, MASS. Soaps containing carbolic acid may b used for cleaning the teeth, without injury. Many, indeed mos of the soaps alleged to contain carbolic acid hold no trace of th agent. They are simply cheap soaps of no special merit.

J. C. C., NORTH VERNON, IND. Gasolene is a very danger ous fluid to use for household illumination. Pour all you hav into the sewer, and never allow, as you value the lives of you family, a single ounce again to enter your dwelling.

E. N. S., CLINTON, IOWA. Naphtha, or what is the sam thing, "Danforth's" *safe oil*, does not explode; it is the air mixed *vapor* which comes from it that causes the terrible deto nations. When the reckless fellow ignites his naphtha to prov that it will not explode, he is deceiving you. No illuminatin fluid is explosive in itself, but there arises a vapor from all the light naphthas, which, when mixed with air and confined in a lamp, will explode with great violence. The vapor even will no explode without the air. Any fluid which will ignite in a warn room when touched with a lighted match, no matter what nam it may bear, no matter what statement may be made regardin its safety, is as dangerous to have in your house as gunpowder *Use nothing but good legal Kerosene Oil, which is cheap enough and you are safe.* It gives off no vapor at ordinary tempera tures, and will not take fire unless heated above 110° F.

G. D. B., BOSTON, MASS. It is probably better to remov plants from sick-rooms, especially if there are many of them To disinfect sick-rooms, the pure carbolate of lime is efficient and cleanly. A teaspoonful or two, allowed to remain open in a saucer, will accomplish the work.

B. P. S., WASHINGTON, D. C. Hydrate of chloral is incom patible with mercury, and the salts of the metal. It should not be administered in association with calomel, or with the alka lies and alkaline earths.

R. G. C., JACKSONVILLE, FLA. Possibly dissolved bones may not be adapted to the dry sandy soil of Florida. The season has much to do with the effects of fertilizers. With a moister season doubtless your success will be greater.

S. M., CONCORD, N. H. Corn is not all constituted alike chemically, each variety having its own peculiar powers of assimilation. Two varieties may *grow on the same cob*, and be entirely dissimilar. Usually the common yellow corn has double the amount of phosphates that is found in the sweet varieties. The *oil* in corn varies from six to eleven per cent. It is analogous to animal fat, and almost by simple transference it takes its place in the adipose substance of animals.

H. O. M., MARSHFIELD, MASS. Your meadow holds undoubtedly what is known as the "vitriol peat." It is sour, unproductive, almost corrosive in its character. It is permeated with the sulphate of the protoxide of iron, and the best way to destroy the deleterious quality is to use carbonate of lime. When carbonate of lime is brought in contact with this salt of iron, mutual decomposition takes place, forming sulphate of lime (gypsum) and carbonate of protoxide of iron; soon the latter substance absorbs oxygen from the air, and the inert protoxide of iron remains. A cask of quick-lime, which soon changes to hydrate, and from that to carbonate, will be sufficient for a cord of the peat.

B. VAN ZANDT of KIT CARSON, COLORADO, wishes a recipe for curing buffalo hides with the hair on. Can any one of our readers give it ?

Medicine.

;ES OF POISONING FROM GALVANIZED IRON WATER-PIPE.

BY J. HEBER SMITH, M. D., MELROSE, MASS.

OLLOWING close upon your earnest protest ;nst the use of galvanized iron pipes for water duction, come some sad cases of zinc poisoning, ch should be recorded for the benefit of the med- profession and families who employ this danger- pipe for the conveyance of water for household I beg leave to submit the following cases occur- in my practice.

bout a year ago Mr. W. P. Sargent, Chairman ie Board of Spot Pond Water Commissioners in town (Melrose), connected his well and a force p in the kitchen with upwards of seventy feet of and a half inch galvanized iron pipe; and to itate the working of the pump, a large reservoir tructed of galvanized iron was placed near to it. hout entering into the details of the minor ail- ts of the family during the past twelve months, ously resulting from zinc poisoning, but which e not sufficiently alarming to be brought to the ce of the physician, it may be stated that in ember last the two daughters were seized a peculiar and persistent inflammation of the at, with extensive ulceration of the pharynx and ils. The ulcers were round, sharply defined, red, everted edges, and gradually coalesced. y were filled with a yellowish white matter. ile convalescing, the youngest, aged five and a years, began to present indications of some un- l derangement of the nervous system. On wak- in the morning, for about ten days, there was re inability to move the head and limbs, with ex- ne sensibility of the whole surface to contact. er about an hour this paralytic state improved ugh to permit walking, but with a staggering, un- ain gait, and a marked tendency to fall to the side. The eyes were turned outward; pupils rnately dilated and contracted, but usually di- d; falling of the upper lids and œdema of the r; objects apparently elongated, and, at times, ble; expression vacant and apathetic or irrita- ; constriction and spasm of the œsophagus dur- deglutition; accumulation of mucus in the nx and posterior nares, with obstruction of both rils and nasal speech. For twenty-four hours ere croupy condition, with symptoms of paraly- of the cervical nerves; considerable gastric dis- ance, eructations, loss of appetite, vomiting of , offensive diarrhœa, alternating with constipa- , and diminished secretion of urine, approaching ne time entire suppression. The pulse, wiry and gular, averaged one hundred and twelve per min- Febrile flushes, with sudden crying out to be ned, and thirst; sleep agitated and unrefreshing, h occasional nightly perspiration. In the evening bility to support the head; great emaciation, ca- etic look, complexion bluish white. On the 15th December, from the general correspondence of symptoms with the records of zinc poisoning, diagnosis and treatment became clear. On same day, the only son, aged thirteen, a very icate child, was indisposed from what had been ught a cold. On examination he presented an aciated, feeble appearance, the face wrinkled and ish; the pulse only forty beats a minute, and in- mitting. There were no other signs of local inflam- tion than a slight tenderness to pressure over the mach, and a dry, spasmodic cough. On Friday, 16th, he was no better, but dressed and lying on sofa. Complained of occasional fleeting pain in hypogastrium on rising, continual nausea, and ire loss of appetite, with disgust at the sight of d; vomited mucus several times the following ht. Sunday morning, vomiting of bile, and indications of intense nausea. Although there were marks of gastric suffering about the mouth, he complained of no pain from pressure over the stomach and abdomen. There was absence of pain or complaint to the hour of his death. Only milk was retained, of which a little was taken at intervals. He vomited again in the evening, and once the following morning, but passed a quiet night in sleep. Monday evening, vomited a brown fluid once, pulse sixty, face flushed, but no delirium nor stupor. Tuesday morning, at six o'clock, he died very suddenly, soon after passing about a gill of disorganized blood at stool. There was slight thirst before death, and faintness. A *post mortem* examination, made by Dr. G. M. Pease, of Boston, and others, confirmed the opinion that the action of the zinc on the nervous centres, inducing paralysis of the heart, was the immediate cause of death. The stomach presented internally marks of a highly inflamed condition, being extensively injected and showing traces of sanguineous exhalation. Dr. Charles T. Jackson, State Assayer, reports, December 23d, that "the water from Mr. Sargent's pump is charged with a very large quantity of the oxide of zinc and a little iron," and that "the zinc renders the water dangerous to health." At the time of his analysis the doctor was not only ignorant of the sickness in Mr. Sargent's family, but also of the source and medium of conduction of the water. At date of writing, January 1st, the little girl, though partially paralyzed in her lower extremities, is fast regaining health and strength. Among other cases of less interest, brief mention may be made of one. Mr. W. B. Burgess, while drinking water conducted by a pipe of this kind, only thirty feet long, had constant dull frontal headache, with occasional attacks of vertigo, preceded by sharp pressure at the root of the nose, and a sensation of drawing together of the eyes, followed immediately by nausea, faintness, and trembling of the hands and weakness of the legs. Examination of the pipe, ordered to be removed from the well, showed a thick incrustation, throughout its whole inside, of a white substance on uncorroded iron, with no traces of its metallic zinc covering. This white powder, analyzed by Dr. J. R. Nichols, chemist, of Boston, was found to consist of carbonate of zinc with a little oxide of iron. This pipe was put in position about six years ago, and more or less water which passed through it has been used in the family.

These cases, with many others occurring in this vicinity, show that zinc is a slow but fatal poison, when introduced into the system through the medium of water, and will serve to put families on their guard against the use of water flowing through galvanized iron pipes.

CHLORODYNE.

In the October number of your valuable Journal of Chemistry, I find an article on the formula of Chlorodyne. During the prevalence of cholera in New Orleans from 1865 to 1867, I used the following formula in its treatment with the greatest success, and never heard of Chlorodyne till 1869.

℞ Chloroform	ʒi.
Morph. Sulph.	grs. xv.
Tr. Camph. fort.	ʒiv.
Tr. Capsici.	ʒij.
Spts. Ammon. arom.	ʒij.
Syrup. Zingib.	ʒij.

From 20 to 60 drops every half-hour or hour, in the first stages of cholera, soon checked and relieved all distressing symptoms (in a large majority of cases) such as nausea, or vomiting, or purging, or crampings. This dose was repeated immediately if rejected, and every half-hour or hour afterwards till the patient was relieved. In addition to this remedy, I invariably used hot fomentations to the extremities by enveloping the patient in blankets wrung out of hot water, and the heat kept up by pouring upon him, thus swaddled, streams of hot water from a tea-kettle. This formula was always immediately tranquillizing in its effect, subduing and relieving the great restlessness and jactitation usually accompanying this disease in its earlier stages. This is a very important object to attain in every case of cholera, as quiet and the recumbent position are *absolutely* necessary to save the patient in a vast majority of cases. In the more advanced or collapsed condition I equally relied upon this formula. To conquer the great thirst, I allowed ice only to be taken into the stomach. After the disease was abated, I of course then directed my remedies to restoring the secretions, etc., of the patient.

This formula was communicated to me by a French physician in New Orleans, who attended a meeting of the medical savants of France in Paris, convoked by order of the French Emperor to investigate this disease in the hospitals of Paris during the great epidemic of 1863–1865. An English physician from London communicated this formula, as the result of this commission's investigation, to his apothecary in London, who immediately compounded it and sent it forth to the world under the captivating name of Chlorodyne. I think upon trial you will find this a most excellent remedy in the treatment of all cases of looseness or gripings of the bowels, or pains from indigestion, or almost any irritability whatever of the system. In cases of insomnia it is fully equal in all respects to the great hypnotic, Hydrate of Chloral, when it is given in teaspoonful doses at bed-time, mixed in two ounces of water. Owen M. Long, M. D.

U. S. Consulate, Panama, *Nov. 4th*, 1870.

DISPENSING MEDICINES.

In the December number of the *Druggists' Circular* is a communication calling the attention of physicians and druggists to the discrepancy between the strength of syrup tinctures and infusions made from Wood and Bache's Dispensatory, and those made from fluid extracts by Tilden's formulas.

Now, it is not generally known by physicians that a large number of their prescriptions for these preparations are made up from fluid extracts, or extemporaneously made from private formulas; but such is the fact.

I will relate one instance of my own experience, which will more fully illustrate how we are imposed upon by those who ought to be above it.

Less than two years ago I took a prescription for Infusion Rhei Comp. to one of the oldest established stores in your city, and asked one of the proprietors how long it would take him to prepare it. He replied two or three minutes; but when I demurred, saying it was too short a time to have a good infusion, he replied, "Your physician may have told you it would take two or three hours; but Dr. So-and-so used to prescribe it, and we always keep it prepared, and the *older* an *infusion*, the *better*."

At the next store I went to, the clerk very kindly offered to make it up in two or three minutes from fluid extracts. It had been put up the day previous at another first-class store in a few minutes, by triturating some powder with hot water in a mortar, the clerk directing the person to "shake well and swallow dregs." And yet you are often told to take your prescriptions to these stores when perhaps you may have to pass some half-dozen where you would be properly served, from the very fact that physicians do not frequent them enough to become familiar with their method of preparing and dispensing, and some they shun altogether. What is the remedy? Go in and familiarize yourselves with those who make and dispense the medicine; and if they are wrong, suggest the right, and then if they heed not, discard them. B. F. Clough, M. D.

Worcester, *Dec.* 10, 1870.

ERYSIPELAS.

In your November number I noticed, among other very able articles, one of value in regard to a specific in Erysipelas, by Dr. T. Temple, of Amherst, Mass. Please permit me to say, that iron has been used in Erysipelas, both internally and externally, for some time past, but it does not necessarily follow that Iodine should be entirely discarded. For many years I have been in the habit of treating Erysipelas, both idiopathic and traumatic, in private and military practice, in the following manner: I surround the margin of the parts inflamed with an inch or less wide stripe of the *etheric* Tr. of Iodine, in order to produce a line of demarcation; this will dry almost immediately; then I cover this band so formed with a coating of collodion, to which, during late years, I have been adding a drop of glycerine. Over the whole I use a thin compress of linen, soaked in a solution of sulphate of iron (about one drachm to the ounce of water), to be renewed as often as it evaporates. I have not yet seen any reason to alter the treatment, being perfectly satisfied with the *modus operandi.*

E. Seyffarth, M. D.

Lawrence, Mass.

PERSULPHATE OF IRON AS A HEMOSTATIC.

October 30th, I was called to a young man with Epistaxis, who had been suffering for three days with hemorrhage, and had been attended by two other physicians without any good result. I plugged the posterior nares; hemorrhage ceased for two or three hours, but began again with symptoms seeming critical.

I took a gum catheter, cut it in two, putting some persulphate of iron into it, and thus blowing it up into the anterior nares, previously removing the plug. I found the hemorrhage ceased in a few minutes, with no return since. I then placed him on a full diet, with a preparation of iron, and now he is at work in good health.

In all cases of minor surgery the persulphate of iron is the great *sine qua non.*

J. W. Foster, M. D.

Camden, Mo.

HYPODERMIC INJECTION OF ATROPINE IN HYSTERIA.

December 6th, 1870. Visited a lady aged thirty-five who for five years has been periodically (usually twice yearly) affected with protracted and exhausting hysteria attended with severe eclampsia.

Usual treatment has generally proved only palliative. Disease generally lasting from ten days to two weeks. Always complaining of peculiar sensitiveness and much pain in the cerebellum and upper portion of the spinal cord.

On the above date, December 6th, injected 1-30 gr. of Atropine into the nape of the neck. In one hour the urgent symptoms ceased, patient slept, on awaking was natural, and has remained thus to the present writing, December 27th, 1870.

Throopsville, N. Y.

MEDICAL MEMORANDA.

The Pulverization of Camphor. — The *American Journal of Pharmacy* contains a note on the pulverization of camphor. Camphor is easily enough reduced to powder by rubbing with a few drops of alcohol; but after a short time the powder will aggregate to crystals, which have to be rubbed down again. If, however, the camphor is reduced to fine powder as above, and then intimately mixed with carbonate of magnesia in the proportion of 10 or 20 grains to the ounce, a powder is obtained which never cakes or forms crystals. H. F. Fish suggested, several years ago, a process in which a drachm of carbonate of magnesia was used to disintegrate 16 ounces of camphor, by dissolving the latter in alcohol and pouring the solution into a gallon of water in which the magnesia was suspended, and letting the whole settle, and collect in a filter.

A New Material for Suppositories. — The solubility of glue in glycerine has been utilized by Mr. Carre in the formation of a new material for suppositories. It may be used for the administration of any medicine except tannin. The material is prepared as follows: —

Take of	Best Glue	4 oz.
	Glycerine	8 "
	Golden Syrup	2 "
	Water	8 "

Soak the glue in the water at a temperature approaching 212° F. until quite soft. Mix the syrup and glycerine, add them to the glue solution, and boil until the mixture has lost about two ounces in weight; remove scum, and pour into an oiled mould or tray. The elastic substance thus produced will keep a long time, but gradually becomes more difficultly soluble. In preparing a suppository, the composition is dissolved in a little warm water, the drug is mixed with it, and the mixture is then run into a mould.

New Remedies for Old Ailments. — Acetate of lead is recommended as a cure for the *toothache.* Put one or two grains into the cavity for a moment, and then spit it out. The relief is instantaneous, and the remedy does not fail in more than eight per cent. of the cases.

La Santé gives the following as a method of removing *corns*: Macerate the tender leaves of ivy in strong vinegar for eight or ten days, then apply them to the corns. This dressing should be applied twice a day, and in a few days the corns will be removed.

For *rheumatism,* a large piece of flannel well sprinkled with sulphur and wrapped about the part affected will often prove a remedy as effective as it is simple.

Mumps. — Dr. Young asserts that muriate of ammonia will cure any case of mumps in forty-eight hours. Give in doses of from fifty to twenty grains every two or three hours. It is equally good in orchitis.

CHILBLAINS AND CHAPPED HANDS.

The returning cold, damp weather brings in its train the seasonable series of complaints, such as chilblains, chapped hands and lips, etc. These appear to be most prevalent just now, amongst those exposed to the inclemency of changeable weather, who possess a fair complexion, delicate skin, and other constitutional predispositions. To those especially liable to these tiresome and painful affections, we recommend as a preventive wearing kid skin gloves lined with wool, which not only keep out the cold, but absorb any moisture that may be upon the hands; and to rub over the hands before washing a small quantity of glycerine, which should be allowed to dry or become absorbed to a partial extent. When chilblains manifest themselves, the best remedy not only for preventing their ulcerating, but overcoming the tingling, itching pain and stimulating the circulation of the part to healthy action, is the liniment of belladonna (two drachms), the liniment of aconite (one drachm), carbolic acid (ten drops), collodion flexile (one ounce), painted with a camel's-hair pencil over their surface. When the chilblains vesicate, ulcerate, or slough, it is better to omit the aconite, and apply the other components of the liniment without it. The collodion flexile forms a coating or protecting film, which excludes the air, whilst the sedative liniments allay the irritation generally of no trivial nature. For chapped hands, we advise the free use of glycerine and good olive oil in the proportion of two parts of the former to four of the latter; after this has been well rubbed into the hands and allowed to remain for a l[e] time, and the hands subsequently washed with [...] tile soap and tepid water, we recommend the be[lla]donna and collodion flexile to be painted, and [the] protective film allowed to remain permanen[tly]. These complaints not unfrequently invade pers[ons] of languid circulation and relaxed habit, who sho[uld] be put on a generous regimen and treated with [fe]ruginous tonics. Obstinate cases are occasiona[lly] met with which no local application will reme[dy] until some disordered state of the system is remov[ed], or the general condition of the patient's health i[m]proved. Chapped lips are also benefited by t[he] stimulating form of application we advocate, but t[he] aconite must not be allowed to get on the lips, o[r] disagreeable tingling results. — *London Chemist a[nd] Druggist.*

Count Moltke, aged 70. — The most potent man in the world just now is General Moltke, a[nd] the days of his years are threescore years and te[n]. We will leave military critics to do justice to t[he] military genius of Moltke, and to say where he is [to] be placed in comparison with Grant, and Wellin[g]ton, and Napoleon, and Marlborough, and the old heroes of the world. What we design now is mu[ch] more simple, but equally interesting. The "si[lent] strong man," about whom one hears so little, wh[o] can be "interviewed" only by Bismarck and by th[e] royal family of Prussia, and without whom all Bi[s]marck's grand designs might have been unavailing, the man who is renewing the art of war, and con[]centrating with such terrible efficiency the whol[e] force and manhood and discipline of Germany, i[s] seventy years old. The King of Prussia, himse[lf] seventy-three, has made him a count in honor of hi[s] seventieth birthday; but to us it is far more inter[]esting to know that he has reached that age, tha[n] to hear that he has become Count Moltke. Gran[t] is not yet fifty years old. Marlborough was al[l] done with war by the time he was about sixty. Na[]poleon died at the age of fifty-two. Wellington's military career was over before the age at which Moltke began to distinguish himself. Indeed, before the war with Austria, Moltke has kept his power and his genius very much to himself.

Here, then, is a point for physiologists, that a man of seventy may alter the complexion of the world, and the relation of nations, and the history of civilization; that he may at this age have physical power for going through arduous bodily exertion, and mental power for solving the most tremendous military problems. Meantime let the example of Moltke cheer old men, and make many young men more modest. — *Lancet.*

French Wine Baths. — A story is told of an American travelling in Paris, who, on recommendation of his physician, took a wine bath. He inquired of the colored man in attendance, whom he had known in America, how they could give a wine bath for 75 cents, and was answered, "Why, massa, that wine has been used one week, and you is the thirty-eighth person who has bathed in it." "Well, I suppose they throw it away when they are done with it." "O, no, massa, they send it downstairs for the poor people, who bathe for 25 cents." "And then what do they do with it?" "Bottle it up and send it to America, where they sell it for French wine."

An American dentist has written a paper to prove that nearly all the "ills that flesh is heir to" come of eating common salt. He says: "While I would not wish to be understood as believing that common salt is the sole cause, I *do* believe that it is *one* of the giant evils that are tending so remarkedly to undermine the health of man, and, with the health, the mind."

Boston Journal of Chemistry.

VOLUME V. BOSTON, MARCH, 1871. NUMBER 9.

Familiar Science.

INFECTIOUS GERMS.

THE spread of the new cattle disease, *epizoötic aphtha*, in this country, under circumstances so remarkable, has awakened in the minds of farmers and others a desire to learn something of the nature of the contagious principle, and the mysterious manner in which it is communicated from one animal to another.

An agent of infection so subtle that a dog or cat walking through a barn where diseased animals are kept, and then running four or five miles in the open air and entering another barn, infects a herd of healthy animals without contact, must be regarded as extraordinary in its nature. After all, it is no more extraordinary or wonderful than the infectious germs of small-pox, scarlet fever, or measles, which are readily conveyed very long distances in the clothing, and in the air, and which remain uninfluenced by meteorological agencies, heat and cold, wet and dry. The susceptibility of different individuals to the influence of contagious germs is no less wonderful than the nature of the germs themselves. It may be said that no two persons are affected alike by them, and it is probable that the same difference prevails among animals. Indeed, we have instances of some herds attacked by the new disease, in which five, ten, and even twenty per cent. of the animals remain in perfect health. They are confined in the same stalls with those diseased, and breathe the poisoned air night and day, and yet not a function is disturbed or a vital movement interfered with. Among human beings, we know that a physician, nurse, or any person leaving a room in which there is a patient sick with scarlet fever or measles, may, in passing a child upon the opposite side of the way, communicate to it the disease; while during the same walk, another may be taken in the arms and suffer no detriment. There is a small class of persons who can never be brought under the influence of kine-pox virus, and such are usually greatly distressed in consequence of this idiosyncrasy of organization. There is but little occasion for anxiety, however, for such will usually escape the more severe disease of small-pox, if exposed to infection. In our view, those who are most readily and severely influenced by vaccine virus are the persons who will be most likely to contract varioloid, when brought in contact with the germs of small-pox; so that the feeling of safety cherished by such is not well founded. There are individuals and families in every community who are continually suffering from every form of malaria, poison, and contagion known to medical men, and certainly they are deserving of sympathy. Personal cleanliness and the strict observance of all hygienic laws are of no avail with thousands in warding off these disturbing agencies; they are the victims of an organization susceptible to the malign influences of poisons and contagions which lurk constantly in the atmosphere, and even in food and drinks.

We know but little regarding the exact nature of the germs which are capable of implanting disease in the system. That they have substance and form, no one can doubt. As distinct atoms or particles of matter, they are inconceivably small, and capable of being buoyed up or supported in air, and carried from place to place through its agency. In a barn containing animals suffering from pleuro-pneumonia, or from the epizoötic aphtha, we must suppose the atmosphere to be loaded with the infinitesimal particles. If our eyes could be opened so that we could see the particles as we see snow-flakes in the winter, what a fearful spectacle would be presented! The disgusting, poisonous atoms would be seen flying in all directions and resting upon everything; upon the clothing of those in charge of the animals, upon the hay, upon the manure, floors, scaffolds, and upon the backs of any dogs, cats, or birds which might be present. A perfect shower of infectious spores would be seen to prevail, and probably we should no longer wonder how the poison is carried so rapidly from one point to another. It is probable that when one or more of these germs are taken into the system through the organs of respiration, a kind of fermentation is set up in the blood, analogous, perhaps, to that which occurs in vegetable substances during the vinous or acetic change.

In studying disease, or any of the changes which occur in the animal organization, we must constantly bear in mind that the body is simply a piece of chemical apparatus, and that all the movements or changes that occur are simply chemical reactions of one form or another. The disease germs themselves are chemical substances; and the difference in chemical composition gives rise to the different forms of blood poison which manifest themselves as scarlet fever, measles, typhus, etc., in human kind, and pleuro-pneumonia, hoof and mouth disease, etc., in animals.

There is reason to suppose that scarlet fever, measles, and typhus ferments resemble albumen in complexity, and like albumen they may be altered in composition and action by heat, alcohol, and other agents. Small-pox ferment is of a different kind, and is remarkable for the small quantity of substance which produces such extraordinary changes. An atom so small that a microscope of the highest power is incapable of defining it, enters the system through the lungs, and passes on into the blood, and from thence into every texture, nerve, and secretion. In a few days the chemical actions of oxidation and nutrition throughout the whole body are completely altered, and the little particle of matter has reproduced itself infinitely. Pustules appear over the whole skin surface, each one loaded with an infinite number of germs identical in nature with the original particle which set in motion the train of disorganizing forces. There is general peroxidation going on; there is inflammation of the ears, the eyes, the mucous membranes, the joints, the serous membranes; everywhere there is great chemical disturbance. This is *small-pox*, and the terribly disgusting, wretched condition of the bodily functions is due to the introduction of a particle so infinitesimally small that no optical instrument can discern, and no balance can weigh it.

The poisonous germs producing intermittent fever, or *fever and ague*, from whatever source they may arise, are probably of a highly complex and nitrogenous nature, and are capable of being dried and carried great distances by the wind. They enter by the mouth with the dust, pass into the blood, and soon produce a kind of fermentation, which results in high fever preceded by a chill. After this is over, the poison is spent in part; but during the remission of from one to three days, sufficient is reproduced to go through the same action again. This remarkable poison, producing intermittent chill and fever, will work on, unless utterly destroyed by medication, until the victim is so far weakened as to falter and die. The ague ferment is totally unlike that producing small-pox and measles, for by the action of the latter the textures of the body are so changed that they are incapable of going through the same process again; but one can have ague a dozen or more times in the course of his life. It is indeed a great mercy that some of our worst zymotic or infectious diseases can attack us but *once*.

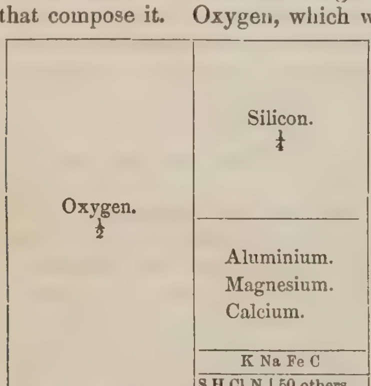
We might as well expect to learn the nature of soul or spirit, as to expect to obtain any precise knowledge of the chemical differences in the germ poisons which affect men and animals. How can we ever know anything regarding the actual difference between a germ producing pleuro-pneumonia or disorganization of the lungs in a cow or ox, and one producing suppurating sores and ugly ulcers in the mouths and hoofs of the animals? Both are specific poisons, exerting specific action upon different parts of the animal organization. It is inconceivable how this can occur; and yet perhaps it is no more inconceivable or mysterious than most diseases, which, after all, are but derangements of the chemical reactions or forces of the animal economy.

We can manage and control chemical changes quite perfectly when they occur in inorganic bodies, and, thanks to science, we can manage tolerably well those which occur in the human or animal organization when they happen under ordinary conditions, and are not of too violent a nature. There is a class of reagents called "remedies," which, when rightly used, serve to control in some degree destructive chemical action in the body. We have learned that the

poisonous germs which we have had under consideration cannot maintain their vitality in the presence of certain chemical agents, among which are carbolic and cresylic acids, sulphurous acid, the chlorides of some of the metals, etc. These destroy the life of spores, as arsenic or prussic acid destroys life in the human body, and therefore they are the proper agents to employ to arrest the spread of infectious diseases. By the exercise of proper caution, and by observing the laws of hygiene, by keeping the body clean, and the blood in good condition, by plenty of air and exercise, we can in a considerable degree fortify ourselves against the attacks of poisonous germinal affections.

SILICON AND ITS COMPOUNDS.

What is the chemical composition of this earth we live upon? The air that envelops the great ball is, as we know, a mixture of two gases, — oxygen and nitrogen, — with a little carbonic acid and watery vapor, and a few other substances in even smaller proportion. The oceans and seas, and all the other waters under the firmament and above the firmament, are also made up of two gases, — oxygen and hydrogen, — with the compounds, comparatively insignificant in amount, which the liquid holds in solution. The solid globe itself — or, rather, its crust, so far as we have been able to examine it — is somewhat more "mixed" in its composition, being made up of a countless variety of substances. If, however, we trace these back to their elements, we find that, as in the case of the atmosphere and the ocean, a few elements constitute by far the greatest portion of the complex mass. The following diagram, for which we are indebted to Prof. Cooke, is intended to show how unequally the *weight* of the earth is divided among the elements that compose it. Oxygen, which we have



already found making up four fifths of the air and eight ninths of the water, is also the most abundant here, forming one half of the whole. Silicon, aluminium, magnesium, calcium, potassium (K), sodium (Na), iron (Fe), carbon (C), sulphur (S), hydrogen (H), chlorine (Cl), and nitrogen (N), fill out nearly the entire remainder. In fact, the thirteen elements already mentioned make up at least 99 hundredths of the whole, while the other fifty elements (including all the useful metals, except iron) do not amount to more than *one* hundredth.

But what *is* this silicon which forms one fourth of the known mass of our earth-crust? Though, next to oxygen, the most abundant of all the elements, it is one of the rarest of substances, on account of the difficulty of obtaining it in a pure state. In this form it is known only as a curiosity in the laboratory of the chemist; but combined with oxygen as *silica*, it is common and cheap, — except when it forms a large ingredient in commercial "fertilizers." Ordinary quartz and flint are pure silica, and the yellow sand of the seashore and the desert is silica contaminated with a little oxide of iron. All the varieties of sandstone, and many other rocks, are mainly made up of it.

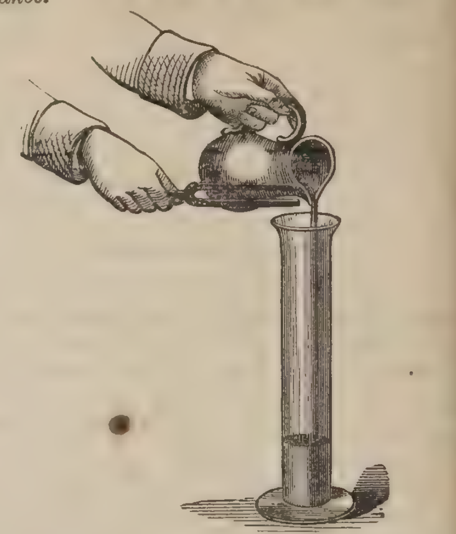
In its chemical relations this tasteless solid is an *acid*, and is known as *silicic* acid. It forms a large class of very important salts, or *silicates*. Among these are the familiar minerals, felspar and mica, which enter into the composition of granite and other extensive rock formations.

Silica is found also in the vegetable kingdom, especially in the grains and the grasses. The outer glossy covering of these plants is mainly this substance, which the plant has sucked up from the earth. There is so much silica in some canes that they will strike fire with steel. Some species of *Equisetum*, or "horse-tail," are used for smoothing and polishing wood, on account of the silicious "grit" in their cuticle. Considerable quantities of the *Equisetum hiemale* are imported into England from Holland for this purpose, under the name of "Dutch rushes." Certain native species are much used by the common people of Great Britain for scouring tin and pewter vessels.

The artificial silicates are of incalculable importance in the arts. When we add that all the forms of *glass* are to be reckoned among these "salts" (for such, chemically speaking, they *are*), it will be readily admitted that their value to mankind is immeasurable. To do justice to so suggestive a theme would more than exhaust the space at our command. In addition to all that we owe to glass in the domestic and the useful arts, consider for a moment how much it has extended the field of human knowledge. There is no one substance to which chemistry has been more indebted for its development and progress. It has given us the microscope, the telescope, the spectroscope, — the windows through which we look out upon the wonders and the beauties of the universe, which were otherwise concealed from our gaze as by thick impenetrable walls. *All* that we know of "the infinitely little," and *all* that we have learned of "other worlds than ours" in the immensity of space, we owe to a few grains of sand fused into chemical union with alkaline earths, — in other words, to a compound of silicon.

RESONANCE.

It is well known that a tuning-fork cannot be heard at any great distance unless its sound is reinforced or strengthened by some contrivance; as, for instance, by attaching the fork to a sounding-box. The figure illustrates another way in which the same result may be attained. If the vibrating fork be held over a glass jar, some eighteen inches deep, and water be poured in slowly and as noiselessly as possible, we find that the sound becomes louder as the column of air in the jar becomes shorter; and when the water reaches a certain level, the sound is all at once greatly augmented. If we continue to pour in water, the sound becomes fainter and fainter until it ceases to be heard. By repeating the experiment we find that there is one particular length of the column of air in the jar which causes the fork to give the loudest possible noise; and this reinforcement of the sound by means of a vibrating column of air is what we mean by *resonance.*



If we try tuning-forks of different pitch, we find that the length of the resonant column of air is not the same for all. The higher the pitch of the fork, the shorter the column will be. Our readers probably know that the *pitch* of sounds depends upon the *rapidity* of the vibrations producing them. The higher the sound, the faster the sonorous body must vibrate. But since all sounds travel through the air with the same speed, the faster the vibrations, the shorter are the sound-waves produced. Now it can be proved — but we shall not take the space to do it here — that the length of the resonant column of air for a tuning-fork is equal to just one fourth the length of the sound-wave produced by the fork. For example, if the fork sounds loudest when the level of the water is 13 inches from the top of the jar (as it will if the fork vibrates 256 times in a second), the sound-wave will be four feet and four inches long.

The experiment we have described is only one out of many that have been devised to illustrate the laws of resonance; and many natural phenomena are due to the same cause. Tyndall, in his "Lectures on Sound," thus refers to some of these: —

"The resonance of caves and of rocky enclosures is well known. Bunsen notices the thunder-like sound produced when one of the steam jets of Iceland breaks out near the mouth of a cavern. Most travellers in Switzerland have noticed the deafening sound produced by the fall of the Reuss at the Devil's Bridge. The noise of the fall is raised by resonance to the intensity of thunder. The sound heard when a hollow shell is placed close to the ear is a case of resonance. Children think they hear in it the sound of the sea. The noise is really due to the reinforcement of the feeble sounds with which even the stillest air is pervaded. By using tubes of different lengths, the variation of the resonance with the length of the tube may be noticed. The channel of the ear itself is also a resonant cavity. When a poker is held by two strings, and when the fingers of the hands holding the poker are thrust into the ears, on striking the poker against a piece of wood a sound is heard as deep and sonorous as that of a cathedral bell. When open, the channel of the ear resounds to notes whose periods of vibration are about 3,000 per second. This has been shown by Helmholtz; and a German lady named Seiler has found that dogs which howl to music are particularly sensitive to the same notes."

SPONTANEOUS COMBUSTION.

A few weeks ago, more than forty thousand dollars' worth of property was destroyed by fire in a furniture manufactory at East Cambridge, on account of carelessness in leaving oily rags lying about. In our January number we devoted a leading article to this subject of spontaneous combustion; and the following communication just received from one of our best chemists furnishes some striking illustrations of the varied ways in which such combustion may arise: —

Any light that can be obtained on spontaneous combustion adds not a little to the value of real estate. We believe a large percentage of the fires charged to incendiarism are really owing to spontaneous combustion, so called. We purpose giving three cases, two of which have come under our own experience.

1. Within a year, twenty-eight rolls of cotton cloth in one of our large dyeing establishments were dyed black, and were delayed a few days before they could be starched and finished. Two of these rolls were discovered to be on fire, — not in flames, but in a smouldering condition, or charred into tinder; a third roll was so hot that hands could not handle the cloth, and the wooden roller upon which the cloth was wound was heated almost to the point of ignition.

The rolls of cloth destroyed were the *first dyed*, and consequently had been longer exposed than the others, which *in a measure* explains why all the rolls were not in the same condition.

In the dyeing, the first rolls were dyed *without washing*, by an oversight of the dyer. This is the *point of importance*, as the chemical salts were left in the cloth. Logwood, potash, sulphate of copper, and sulphate of iron constituted the dye, and we suggest this explanation of the probable cause of the fire. The potash and sulphate of iron change to sulphate of potash and hydrate of iron; the latter changes to oxide of iron by the absorption of oxygen from the atmosphere or from moisture in the cloth, and the heat thus developed reaches the point of ignition. Cloth in drying is very liable to contain heated moisture.

2. Within a year a fire was discovered in a silk-mercer's shop in London. The fire originated in a lot of *black-dyed silk*, and was discovered, as in the first instance, before flame had burst out. The conclusion reached was that it was not safe to have black-dyed silk in large masses, and that each piece ought to be so placed as to allow a free circulation of air. We think it quite probable that the explanation of the combustion is the same as in the preceding case.

3. In trying to get rid of rats in a dwelling-house, the floors were taken up, in order to cut off their ingress, if possible. The box that held the hot-water pipes was found to be a favorite resort for the vermin, and had *actually been on fire*. The sides were charred, but there had not been sufficient air to sustain combustion. Upon investigation as to the cause of the incipient fire, we were not left long in doubt, for a store of remnants of greasy cloths used in washing dishes was found, which had been brought by the rats from the kitchen. Some of these were charred, and the others were well saturated with grease and oils. This fire was quite a distance from the kitchen range, forty feet at the least.

It would be very natural in all these cases, if the real causes had not been so apparent, to attribute the origin of the fire to incendiarism.

We have a very firm impression that the introduction of coal oils for lubrication of machinery has very materially reduced the numbers of fires from spontaneous combustion, owing to the fact that the coal oils *do not absorb oxygen*; and that for this reason, if for no other, insurance companies can afford to insure mill property for less rates than they charge at present.

THE SIZE OF THE SUN.

More than one attempt has been made to convey some adequate idea of the vast bulk of the sun as compared with the earth. The following, which we take from Mr. Proctor's "Other Worlds than Ours" (recently reprinted by the Appletons), is very good in its way, and may serve as an average sample of an exceedingly interesting book: —

"Let the reader consider a terrestrial globe three inches in diameter, and search out on that globe the tiny triangular speck which represents Great Britain. Then let him endeavor to picture the town in which he lives as represented by the minutest pin-mark that could possibly be made upon this speck. He will then have formed some conception, though but an inadequate one, of the enormous dimensions of the earth's globe, compared with the scene in which his daily life is cast. Now, on the same scale, the sun would be represented by a globe about twice the height of an ordinary sitting-room. A room about twenty-six feet in length, and height, and breadth, would be required to contain the representation of the sun's globe on this scale, while the globe representing the earth could be placed in a moderately large goblet.

"Such is the body which sways the motions of the solar system. The largest of his family, the giant Jupiter, though of dimensions which dwarf those of the earth or Venus almost to nothingness, would yet only be represented by a thirty-two inch globe, on the scale which gives to the sun the enormous volume I have spoken of. Saturn would have a diameter of about twenty-eight inches, his ring measuring about five feet in its extreme span. Uranus and Neptune would be little more than a foot in diameter, and all the minor planets would be less than the three-inch earth. It will thus be seen that the sun is a worthy centre of the great scheme he sways, even when we merely regard his dimensions.

"The sun outweighs fully seven hundred and forty times the combined mass of all the planets which circle around him; so that when we regard the energy of his attraction, we still find him a worthy ruler of the planetary scheme."

HOUSEHOLD RECIPES.

Liquid Bluing. — To one part of Prussian blue add gradually two parts of concentrated muriatic acid. Let the paste stand for twenty-four hours, then add nine parts of water, and bottle it.

The solution of indigo in sulphuric acid is also used for the same purpose. To prepare it, pulverize one ounce of pure indigo, and add it by degrees to four and a half ounces of concentrated sulphuric acid, mixing it well by stirring with a glass rod. If desired, the acid may afterwards be neutralized with carbonate of potash.

Yeast. — The following is recommended by first-rate authority as a method of making good yeast that will keep for weeks, even in hot weather: —

On Monday morning put two ounces of best bale hops into a gallon and a pint of cold water, boil half an hour, strain hot, and dissolve two ounces of finest table salt and half a pound of sugar in the liquor; when cooled to new milk warmth, put one pound of sifted flour into a large basin, make a well in the centre of it with the hand, and add the liquor by degrees, stirring round and round with a spoon until the whole of the flour is evenly mixed with the liquor; set the pan containing the liquor on a stool by the stove, in winter time, day and night. In hot weather this is not requisite. On Wednesday morning boil and mash finely three pounds of good potatoes, and mix them with the liquor in the same way as the flour. On Thursday morning there should be a heavy dark scum on the surface. The yeast must now be stirred thoroughly and strained through a sieve or colander into a gallon jug, corked firmly, tied down, and placed in a cool cellar. Shake well before using.

To Remove Grease from Silk. — Rub together fine French chalk and spirits of lavender to the consistence of a thin paste, and apply thoroughly to the spots with the fingers; place a sheet of brown or blotting paper above and below the silk, and smooth it with a moderately heated iron. The French chalk may then be removed by brushing.

Paste that will Keep a Year. — Dissolve a teaspoonful of alum in a quart of warm water. When cold stir in as much flour as will give it the consistency of thick cream, being particular to beat up all the lumps; stir in as much powdered rosin as will lie on a dime, and throw in half a dozen cloves to give a pleasant odor. Pour this flour mixture into a pan containing a teacupful of boiling water, and stir it well over the fire. In a very few minutes it will be of the consistency of mush. Pour it into an earthen or china vessel; let it cool; lay a cover on, and put in a cool place. When needed for use, take out a portion and soften it with warm water. Paste thus made will last twelve months. It is better than gum, as it does not gloss the paper, and can be written on.

Curing Beef and Hams. — The following recipe has been used for forty years by a manufacturer who is noted for the superior quality of his dried beef and hams: —

For every 100 lbs. of beef, 7 lbs. salt, 2 oz. saltpetre, $1\frac{1}{2}$ lbs. brown sugar, 4 gals. water. Boil and skim, and pour over the meat when cold. If properly packed, that amount of water will cover the meat.

For pork, pack the hams and shoulders together. To every 100 lbs. take 8 lbs. salt, 4 oz. saltpetre, $1\frac{1}{2}$ lbs. sugar, 4 gals. water.

The hams and beef for drying may be taken out after four weeks. To keep the meat after warm weather, the pickle will have to be boiled.

A Cheap Breakfast for Eight Persons. — "A good breakfast for eight persons for about a dime. Put half a pound of rice and half a pound of Scotch barley into one gallon of soft water; stew them gently for four hours. Then add four ounces of molasses and a little cinnamon; boil another half-hour. This will produce eight pounds of good food."

The above quotation, clipped from a journal ostensibly devoted to the promotion of health, is a fair sample of the teaching of many of these pseudo-medical publications. The entire amount of solid matter contained in this "mess" is twenty ounces, which gives each person of the eight two ounces of farinaceous food and one half an ounce of molasses for a breakfast. The writer of this recipe ought to be made to take three meals per diem of his "pap" for three weeks. If at the end of that time he should retain strength to write another, we will concede that six ounces of mixed rice and barley and an ounce and one half of molasses are a liberal day's rations for an adult. — *Scientific American.*

Economical Board. — It is said that the hunters of Siberia, when pressed by hunger, take two pieces of board, and, placing one on the pit of the stomach and the other on the back, gradually draw together the extremities, and thus allay, in some degree, the cravings of appetite.

The Arts.

A STEAM LOCOMOTIVE FOR COMMON ROADS.

Ever since the introduction of railways, the problem of the adaptation of the steam-engine to travel upon ordinary roads has attracted more or less attention, but until recently every attempt to solve it has proved a failure. At last, however, we have a road locomotive that both works well and wears well. "Thomson's road steamer," as it is called, is already much used in Europe, and a manufactory for building it has been established in New Jersey. The English manufacturers are unable to fill their numerous orders, and have had to give a firm in Scotland the right to supply that country.

The most important feature in the machine is the construction of the driving wheels, which have a broad rim, covered by a thick india-rubber tire, which is itself surrounded by an endless chain of steel plates. This chain, the rubber tire, and the rim of the wheel are not fastened together; so that, in running, especially with a heavy load, the tire slips gradually around the wheel, and is thus saved from being torn by any sudden strain upon it.

The steering apparatus is simple, and the steamer can turn a very sharp corner, the inner driving wheel describing a circle of less than three feet radius. The gearing and working parts are strongly constructed, and protected from dirt and the weather. An ingenious device in connection with the exhaust steam suppresses almost entirely the noise caused by its escape. There is a single gear for quick speed, and a double gear for heavy loads. Either of the driving-wheels can be thrown in or out of gear, so that, in turning corners, the inner wheel is out of gear while the outer wheel drives the steamer around. Two sizes are made, of 8 and of 12 horse power, which draw loads of 20 and of 30 tons, respectively, on an ordinary level road, and 12 and 17 tons up inclines of 1 in 12. The speed is $2\frac{1}{2}$ to 6 miles per hour for freight steamers, and 10 miles for passenger service. The consumption of coal is about half a ton daily.

This engine not only travels over soft roads without injuring them, but it actually repairs and improves them. This was well illustrated in one of the English experiments, where the steamer, with a heavy vehicle attached, was driven round and round in a field thoroughly saturated with melted snow. The steamer left the merest track in the slushy ground, while the wheels of the vehicle behind cut it into deep ruts. But as the engine passed over these ruts, when retracing the circle, it effaced them; and by and by, being detached and allowed to run over the spot alone, it repaired the surface, and made it perfectly smooth and even.

An eight-horse-power steamer has been in use for many months, making six trips daily from Aberdeen, Scotland, to some flouring mills, three miles distant, and carrying a load of ten tons each time. The road on which it travels is described as "perhaps the worst road in the kingdom," being narrow and crooked, and with gradients for half the distance varying from one in nine to one in eight. Up these inclines the steamer, which weighs six tons, draws a load of ten tons. We may add, to give a better idea of these grades, that the steepest incline on the road over the Simplon Pass, in Switzerland, is one in thirteen.

On the whole, this new engine, which virtually converts all our highways into steam railways, is to be considered as one of the most important inventions of this inventive age.

MEMORANDA IN THE ARTS.

Compressed Air as a Motive Power. — The success which has attended the use of compressed air as a means of transmitting power, in the operations at the Mont Cenis tunnel, has had much to do with the completion of that great enterprise. It would have been quite impossible to carry steam at a high pressure through pipes four miles long; but it was found that very little force was lost in working with air, although all the engines and condensers, as well as the cylinders for storing the air, were outside the mouth of the tunnel. No heat is produced in a tunnel by this process; but, on the contrary, since the escaping air absorbs heat as it expands, it serves at the same time to cool and to ventilate the interior.

It is not improbable that the same means may come to be employed for transmitting the power of waterfalls to great distances, as proposed by Mr. Day, of Bloomingdale. It is in this way that he would convey to Buffalo five thousand horse-power taken from Niagara Falls, twenty miles distant. It is estimated that this may be done by means of a pipe 42 inches in diameter, through which a column of air, compressed so as to exert a force of 100 pounds to the square inch, is sent with a velocity of 10 feet a second; or a pipe of 36 inches would do, if the velocity were $14\frac{1}{2}$ feet a second. It is proposed to make the pipe of boiler iron a quarter of an inch thick, and to paint it inside and out with a strong indestructible varnish, which will at once make it absolutely air-tight and protect it perfectly from corrosion. We shall not be surprised to see the project carried out.

To Cut or Bore Glass. — Any hard steel tool will cut glass with great facility when kept freely wet with camphor dissolved in turpentine. A drill-bow may be used, or even the hand alone. A hole bored may be readily enlarged by a round file. The ragged edges of glass vessels may also be thus easily smoothed by a flat file. Flat window glass can readily be sawed with a watch-spring saw by aid of the solution. In short, the most brittle glass can be wrought almost as easily as brass by the use of cutting tools kept constantly moist with camphorized oil of turpentine.

Parchment Paper. — Paper can be readily converted into vegetable parchment by immersing it for a few moments in a mixture of two volumes of sulphuric acid and one of water. The acid should be washed off the paper by immersing and slightly agitating it in a large quantity of cold water. The last trace of acid may be removed by finally immersing the paper in water to which a small quantity of ammonia has been added. To prevent contraction or wrinkling, the paper should be stretched on a frame while yet wet. Paper so prepared is transparent, and can be used for tracing paper; and may also be employed as a very good substitute for sheepskin parchment.

To Fuse Platinum with the Common Blow-pipe. — It has been found that if the loss of heat by conduction be prevented, platinum can be fused with an ordinary blow-pipe blast through a candle or lamp flame. This is effected by using, instead of the metallic nozzle, a tube of clay or glass. In this way Mr. Skey fused fine platinum points to beads. To make sure that the metal was not rendered more fusible by admixture of other substances, he prepared some pure platinum with special care for experiment; and with this he obtained the same result. As the fusing point of platinum is 4,593° F., it is evident that even that high temperature can be produced by the ordinary blow-pipe, if no heat is wasted.

PRACTICAL RECIPES.

Water-Proof Packing-Paper. — Water-proof packing-paper is now made by some manufacturers. The paper is covered with a resinous liquid, then painted over with a solution of glue and soot, as without this the paper will later show blotches. After this is dried, the actual water-proof coat is applied. This is prepared with two and a half ounces of powdered shellac, dissolved in two pints of water, which is gradually brought to boil, and is stirred until the substance is perfectly dissolved and softened; when gradually one third ounce of powdered borax is added, until an intimate union of the substances takes place. The liquid is then left to cool, and while still hot any mineral color may be added, such as lamp-black, yellow ochre, red ochre, iron blue, or burnt umber, after which it is left to get entirely cold. It is then ready for use. The operation can be so quickly performed with a brush that two women can prepare three thousand feet in ten hours.

Turner's Cement. — The following is a very excellent cement for the use of turners and artisans in general: sixteen parts of whiting are to be finely powdered and heated to redness, to drive off all the water; when cold, this is mixed with sixteen parts of black resin and one part of beeswax, the latter having been previously melted together, and the whole stirred till of uniform consistence.

Printing Ink. — An extemporaneous superfine black ink may be made by the following formula: Take of balsam of copaiba (pure), 9 oz.; lamp-black, 3 oz.; indigo and Prussian blue, of each $\frac{1}{2}$ oz.; Indian red, $\frac{3}{4}$ oz.; yellow soap (dry), 3 oz.; grind the mixture to an impalpable smoothness by means of a stone and muller. Canada balsam may be substituted for balsam of copaiba where the smell of the latter is objectionable, but the ink dries very quickly.

Indelible Ink for Type. — The *Druggists' Circular* gives the following recipes for making ink to be used with type or stencil plates: —

1. Sulphate of manganese, two parts; lamp-black, one part; sugar, four parts; all in fine powder and triturated to a paste with a little water.

2. Black oxide of manganese and hydrate of potassa are mixed, heated to redness in a crucible, and then triturated with an equal weight of *pure white clay*, and water enough to give consistency. The work is to be rinsed well in water after it is dry.

To Revive the Color of Faded Black Cloth or Leather. — Take of the best quality of blue galls, four ounces; of logwood, clean sulphate of iron, (copperas), clean iron filings, and sumac leaves, each one ounce; put the galls, logwood, and sumac berries into one quart of the best white wine vinegar, and heat to nearly the boiling point in a sand bath, then add the iron filings and copperas; digest for 24 hours, and strain for use. Apply with a sponge.

Furniture Oil. — To one quart of linseed oil add one ounce of bruised alkanet root, and boil them together in a glazed earthen vessel until the color is extracted from the root; then cool, and strain for use.

Curing Skins without Removing the Hair. — A correspondent sends the following recipe for curing skins without removing the hair.

Take of soft water	10 galls.
Wheat bran	$\frac{1}{2}$ bushel.
Salt	7 lbs.
Sulphuric acid	$2\frac{1}{2}$ lbs.

Dissolve all together and place the skins in the solution, and allow them to remain twelve hours; then remove and clean them well, and again immerse twelve hours, or longer if necessary. The skins may then be taken out, well washed, and dried. They can be beaten soft if desired.

Agriculture.

HOW TO PREPARE BONES FOR FERTILIZING USES.

We have repeatedly given information in the Journal regarding the best and most convenient methods of preparing bone material for the farm and garden, but requests still come for further or more specific instructions. If a farmer has collected a pile of bones which he desires to utilize or fit for plant food, he can accomplish the end in two or three different ways: 1st, by dissolving them in sulphuric acid in the raw condition; 2d, by dissolving after burning to whiteness; 3d, by dissolving them in connection with caustic lye from ashes and soda. Bones cannot be dissolved in acid economically, unless they are reduced to a fine powder. Pounding them into small fragments will not do, as but a part of the bone substance can be acted upon by the acid when fragments are submitted to its action. An insoluble coating of sulphate of lime forms around each fragment after the first action of the acid, and this arrests further decomposition. As a matter of experiment, we have submitted powdered bones to the action of strong and dilute acid, for six months, and the solution at the end of that time was far from being complete. Raw bones are very difficult to grind in any mill accessible to farmers, and therefore it will be best, if it is desired to make "superphosphate," to construct a rough kiln of stones, throw into it the bones, along with sufficient wood to kindle them; and by igniting the wood, the bones will readily take fire and burn to whiteness. In this state they are brittle, and can be ground in a bark, plaster, or grist mill. The organic matter, or the gelatine, is destroyed in this process, and the bones lose about twenty-seven per cent. in weight. To convert the bone ash into superphosphate, procure two or three good sound molasses casks, divide them in the middle with a saw, and into each half put two hundred pounds of the powder moistened with a couple of buckets of water. A common hoe may be used to turn over and mix the powder and water, and also it may be used to stir up the mass after the acid is added. Oil of vitriol or sulphuric acid should be purchased in carboys, and the common commercial strength is suitable, that of specific gravity 1.70, or 140° Twaddell. A stone pitcher holding a gallon is a suitable vessel in which to receive and measure the acid; and in turning it out of the carboy, do not be nervous or act in a hurry. Turn it out gently, and be careful that it does not spatter upon the face or clothing. Place the carboy upon a low box, remove the stopper, and, tipping the vessel, allow a small, smooth stream to fall into the pitcher. The two hundred pounds of bone powder will require the entire contents of the carboy of acid; in fact, a little more is needed to produce perfect decomposition. A carboy holds about one hundred and fifty pounds, and one hundred and seventy-five will be appropriated by the bone if the action is perfect and entire. The contents of a carboy, however, have answered in our experience. The acid must be added gradually, one gallon at a time, stirring with the hoe, and waiting for the effervescence to subside before more is added. In a few hours the action will be over, and a liquid resembling water will be seen floating upon the top of the powder. This liquid is *excessively sour, being free phosphoric acid*, holding a little soluble lime in combination. Many who have tasted of this liquid have supposed that it was *uncombined oil of vitriol*, and, fearing that it would *burn up* their crops, have been afraid to use the mixture. To *dry* this pasty mass, so that it can be pulverized, is the most troublesome and protracted part of the labor. Superphosphate should be made by the farmer *in the summer* after hoeing, when the weather is warm. He should provide twenty or thirty rough shallow boxes, in which the moist mass can be placed and put in the sun to dry. They can be taken under cover in wet weather. Before drying, a barrel of sifted loam should be mixed with the bone paste, and thoroughly worked into it. This will greatly facilitate the drying process. When the mass is dry, it can be pounded fine with a mallet, or it can be ground in any kind of a mill. The powder thus manufactured is most excellent, and when further diluted with two more barrels of dry soil or loam, is equal to the best superphosphate found in the market. A handful put in each hill of corn or potatoes at time of planting will give fine results. This superphosphate *must not be mixed with lime, or ashes*, as from their action it will undergo decomposition, and new salts will be formed. It may be mixed up with dry fish pomace, and form a very perfect and excellent fertilizer for all kinds of crops.

The manipulation described above is adapted to the preparation of superphosphate from ground *raw bones*. The only variation is in the amount of acid needed. *For raw bone powder, only half as much acid should be used*, or six gallons for a barrel of bone dust. The processes for its manufacture are the same. Bones may be dissolved in moistened wood ashes, if care is taken to bring them completely under the action of the caustic lye.

To accomplish this, it is necessary to break the bones into fragments and pack them in a tight, shallow box with an equal weight of good sound wood ashes. Mix with the ashes, before packing, twenty-five pounds of slaked lime and twelve pounds of powdered sal soda (carbonate of soda) to every one hundred pounds of the ashes. The box in which to conduct that process may be made of rough boards, but it must be tight, and it should not be over eighteen inches deep. It may be as broad as is necessary. The bones should be packed in layers; first upon the bottom a layer of ashes, then a layer of bones, and so alternately until the box is filled. About twenty gallons of water must be poured upon the heap (that is, for every one hundred pounds of bones) to saturate the mass, but more may be added from time to time to maintain permanent moisture. In three, four, or six weeks, the bones will be broken down completely, and the whole may be beaten up together, after adding an equal bulk of good sifted soil. This compost is of the highest efficacy, as it embraces quite all the great essentials of plant food, namely, potash, soda, lime, phosphoric acid, and the nitrogenous element. This is a very convenient way for farmers who have ashes, to dispose of their store of bones. If plenty of ashes can be procured, it will facilitate the decomposition of the bones to employ *twice* as much ashes as there are bones: the solution will be effected sooner, and more perfectly.

If powdered bones are employed, a barrel of the powder may be mixed with a barrel of good ashes, and the whole turned into the half of a molasses cask, moistened with two bucketfuls of water, and stirred up well with a hoe. In a week this will be ready for use, and it forms a most efficient and convenient fertilizer for all the cereal crops. We think it does more for corn, in giving plump, full kernels, than any concentrated fertilizer we have employed. A handful is enough for a hill, put in at time of planting. Before dropping the seed, a little earth should be kicked over the powder, so that it may not come in direct contact with it.

In the statements above given, we have but repeated, although in another form of words, what we have many times before stated. We have endeavored to give the processes for preparing bones, in the most practicable way, and in words unaccompanied with technical phrases. This must make all plain to the comprehension of every reader. Our statements are based on actual experience, and experience probably more extensive than has fallen to the lot of most others.

If farmers will place the paper containing these statements where it can be readily found when wanted, it may be of great service in the conduct of their farms, and it will save them the trouble of writing, and us the trouble of replying, when they desire information upon the proper treatment of bones for fertilizing uses.

ASHES, LEACHED AND UNLEACHED.

Wood ashes have been recognized and used as a manurial agent by nearly or quite all the civilized and semi-civilized nations that have ever existed on the earth. The Roman farmers in the days of the Republic and the Empire were in the habit of burning the stubble of their grain fields and using the ash to enrich succeeding crops; and that stern old husbandman Cato recommends the burning of twigs and branches of trees, and spreading the ash upon lands. The Indians of this country and of South America were led by observation to know the value of ashes, and often burned the stems and leaves of the corn plant to improve the soil. There has never been a time, however, when a higher value was placed upon ashes than the present, and this estimate is by no means an exaggerated one. Inquiries are frequently made regarding the comparative value of leached and unleached ashes; and in order to answer them, let us consider the nature or chemical constituents of the two heaps as we find them at the soap-boiler's. In one bin are the dry, fresh wood ashes; in another the wet, lixiviated mass as thrown from the leach tubs. If the former are like the ashes produced in our own dwelling, by burning in the open fire-place oak, pine, hickory, birch, and maple woods, a bushel will weigh about 50 lbs., six and three fourths pounds of which are soluble in warm water. Of the soluble constituents there are a little more than $4\frac{1}{2}$ pounds of potash and soda, the remainder being the sulphuric, muriatic, and carbonic acids with which the alkalies are combined. Forty-three pounds are *insoluble* in water, and consist of

Carbonate of lime	32 lbs.
Phosphate " "	3 lbs.
Carbonate of magnesia	4 lbs.
Silicate of lime	3 lbs.
Oxides of iron and manganese	1 lb.

It is the work of the soap-boiler to remove from ashes that which is soluble in water, which is accomplished in the leach tub, and this is all the change they undergo in his establishment. The ashes go in dry, holding the soluble and insoluble substances; they come out wet, deprived of $6\frac{2}{4}$ pounds of potash and soda. It should be stated, however, that about one pound of quick-lime is added to each bushel of ashes in the leach, to render the lye caustic. This adds one pound more of lime to the insoluble residuum, or the leached ashes, making it weigh, if it was free from water, 44 pounds. In leaching, the ashes do not change much in bulk, but they are largely increased in weight from the contained water.

Now, what is the commercial value of the ashes before and after they pass through the soap-maker's hands? In the dry state the

$4\frac{1}{2}$ lbs. of potash and soda are worth	6 cts. per lb.	27 cts.
Other soluble constituents		3 cts.
32 lbs. carbonate of lime		3 cts.
3 lbs. phosphate of lime		6 cts.
3 lbs. silicate " "		0 cts.
Iron and manganese		0 cts.
		39 cts.

This estimate, which is a fair one, gives a value per bushel of 39 cts., that is, the substances found in a bushel of good sound wood ashes are worth in the market that sum at the present time. By leaching the ashes, 30 cts. of the commercial value is removed and converted into soap; this leaves 9 cts. as the value of the constituents of a bushel of leached ashes. The silicate of lime and the metals practically have no market value, and are not considered.

What is the agricultural value of the two forms of fertilizers? The ashes holding all their normal constituents are worth more applied to soils than for other uses when separated, dollars and cents being considered. A bushel judiciously employed will return in most seasons 60 or 70 cts. worth of products the first year. The potash and soda combined as they are in ashes, in the form of carbonates, sulphates, and silicates, are in precisely the right condition to be readily assimilated, and also to aid in rendering assimilable many important constituents of the soil.

The leached ashes also are worth more to the farmer than 9 cts. the bushel. Relatively they are worth more for soil employment than the unleached, regard being had to the commercial value of the substances when separated. A good honest bushel of moist leached ashes will give returns the first year of the value of 15 or 20 cts.; and owing to the peculiar decomposing influence upon the insoluble constituents of the soil of the silicates, etc., remaining in the mass, their influence extends outside of themselves, and continues for a long time. A pound of phosphate of lime found in ashes is worth more than a pound of bone dust, as it is in a condition to be readily taken up by plants. The carbonate of lime, we are inclined to think, is worth more than chalk or the same agent in other forms, inasmuch as it has once passed through plant structures.

The estimates here presented are only rough ones, but they are sufficiently exact to serve as a guide in learning the value of leached and unleached wood ashes. We have experimented considerably with ashes in both forms, upon soils of various kinds, and what we have here stated is the result of our practical experience. We shall present soon another article upon ashes, as there is need of more extended remarks than we have room for at present.

COTTON-SEED AS A FERTILIZING SUBSTANCE.

It is pleasant to learn of the great interest felt in agricultural matters at the South. Earnest inquiries are made by soil owners and planters in all directions as regards the most improved methods of cultivating, not only the cotton, but the cereal crops. The best farm implements are brought into requisition, and fertilizing substances are sought for in all quarters. We would caution our Southern friends against the frauds and deceptions connected with commercial fertilizers. They cannot afford to throw away their money in purchasing the worthless compounds which flood the Southern market. They must resort to every expedient to increase home products of manure. No waste should be allowed either in connection with households, stables, or vaults. Many questions come to us regarding the best methods of converting cotton seed into fertilizers. Without having had opportunity of experimenting in this direction, we incline to the opinion that it is not profitable or practicable to use fresh cotton-seed for manurial purposes. If composted, which of course is the readiest way of utilizing it, we think the large amount of oil held in the seeds would interfere with the process of fermentation. We do not well see how a rich oil could be brought readily under the influence of putrefactive changes. The other portions of the seeds would change by fermentation if the oil was removed. The following is an analysis of cotton-seed, whole, and with the husk removed.

	Whole Seed.	Decorticated Seed.
Water,	11.34	8.29
Oil,	6.18	16.05
Albuminous compounds.	23 72	41.25
Gum, sugar, mucilage,	30.98	17.44
Woody fibre,	21.24	8.92
Mineral matter,	6.54	8.05
	100.00	100.00

The demand for cotton-seed oil is increasing rapidly both at home and abroad, and it will continue to command high prices for many years. It will manifestly be better first to express the oil, and then use the remaining rich constituents of the seeds for plant fertilization. If practicable at the South, it would be better to feed the cotton-seed cake to animals, as it is a rich milk-producing and fattening food, and then save the solid and liquid excrement of the animals for the land. There is much to be learned as regards the best course of procedure for Southern farmers, but there are good advisers and many excellent agricultural journals in that section, and improvement must be rapid.

KAINIT.

A NEW fertilizing agent has been recently introduced into the European markets under the name of *Kainit.* It is found as a natural product, in immense quantities, in Germany, and the mines open up an almost inexhaustible supply of *potash.* This is one of the most important discoveries of modern times, and it cannot fail to be of great service to agriculture. With plenty of potash coming to us at cheap rates from natural sources, and with the phosphates from our own immense deposits in South Carolina and New Jersey, the future of agriculture is full of promise. We must not expect to reap immediate satisfactory advantages, as it is by slow processes that the gifts of nature are made fully available. But the time is near at hand when plant food will be furnished in great abundance, and at low prices, to husbandmen everywhere.

Kainit in commerce is a calcined and ground product, and according to analysis contains

Sulphate of potash	30.00
" " magnesia	20.00
Chloride " "	5.00
" " sodium	35.00
Sulphate of lime	10.00
	100.00

The product is not uniform, as it varies in quality in various localities or parts of the same deposit. These potash, magnesia, soda, and lime salts are all of great utility in agriculture, and we think kainit, as soon as it is understood, and the best methods of preparation or combination are known, will be largely employed.

Mr. C. D. Hunter, experimental chemist on the farm of our friend, Wm. Lawson, Esq., Blennerhasset, England, made some experiments with kainit upon potatoes and other crops last year; and although he did not find it to give results equally satisfactory with muriate of potash, still its effects were promising. If the highest results depend upon the *form* in which potash is presented to the soil, methods will soon be devised by which the potash found in kainit will be placed in the most available condition. Mr. Hunter's experiments are fully presented in the *North British Agriculturist*, of December 28, 1870.

A Baltimore house (Mr. C. L. Oudesluys) has commenced to import kainit, and we shall procure a supply, and after full experiment during the coming season will give our readers the results in detail.

THE LESSON OF THE RECENT DROUGHT.

THE following extract is from a Report by W. W. Daniels, Professor of Agriculture in the University of Wisconsin, which we find in that excellent journal, the *Western Farmer:* —

"While there is no means of preventing the recurrence of these extremes of climate, and perhaps no means of modifying their effects that will be universal in its application, there is a remedy, general in its nature, which is within the reach of all farmers. It is the *adoption of a better system of culture,* — better and deeper ploughing, better cultivating, and better manuring.

"The stratum of soil needs to be deepened, to be more thoroughly pulverized, and to be made richer. Any means that may be adopted, that will accomplish these ends, will be of value as a remedy against drought.

"There is another means of preventing the evil effects of both droughts and floods upon all clay lands or upon those having a clay subsoil, and which at the same time increases the productiveness of the soil as to pay well for its adoption. It is under-draining. The effect of under-draining is to pulverize the soil by natural means to nearly or quite the depth of the drains, and by this deep pulverization the soil is enabled successfully to withstand droughts so severe as to ruin crops upon similar land undrained, while the drains beneath the surface form a ready means of escape for the surplus water of wet seasons. In the adoption of a thorough system of under-draining upon all heavy soils will be found the most effectual remedy, and the one most general in its application, against such extremes as those of the past three seasons."

SEEDS AND CUTTINGS.

To prevent balls of snow on horses' feet, let the hoof and fetlock be well cleaned and then rubbed with soft soap previous to their going out in snowy weather. — A drove of 98 Merino sheep, selected from the best stock in Vermont, were sent overland to California recently. — A Down East cow has furnished 365 pounds of butter in a year, besides bringing up a calf to 110 pounds. — Mr. Thos. Meehan states, in Forney's *Press*, that a respectable firm in this country has received a "confidential" circular from Hamburg, Germany, offering to furnish at a low price three hundred cwt. of *sand* for mixing with clover-seed; and the parties claim that they do a large business in that line in England. — Out of six million owners of real estate in the whole country, more than two thirds are farmers. — California expects soon to raise all the raisins needed for home use, with possibly a surplus for exportation. — The State entomologist of Missouri says that the washing of fruit-trees with soap, or the application of any alkaline solution, is an infallible protection against borers; and this is confirmed by the experience of some of the most extensive fruit growers in that section. — The mole is a friend to the farmer, and not an enemy, as he is popularly considered; it having been proved by experiments upon the animal in captivity, that while he readily eats insects, grubs, and the like, he will sooner die of starvation than eat roots or other vegetable substances.

THE CURRANT WORM. — We are informed by Dr. E. Worcester, of Waltham, Massachusetts, that the currant worm, so destructive to a favorite fruit, may be fully and almost immediately destroyed by the use of *carbolate of lime.* The Doctor tried the powder in many instances during the past summer, and found that while it was fully as effective as hellebore, it was less disagreeable, less costly, and perfectly safe. The method of using it is to sprinkle it over the vines as soon as the worm makes its appearance, bringing it well in contact with the leaves, and soon the insect is destroyed. It will need but two or three applications, and the work is done. In this way for a few cents large quantities of currant bushes may be saved and the fruit allowed to mature, and no danger whatever incurred. Neither the foliage nor the fruit is in any way injured by the carbolate of lime. It will be well for our readers to remember this when the fruit season returns.

THE NEW BIRDS. — The new South American birds which we are endeavoring to domesticate at Lakeside Farm, the *Palvons* and *Pauheils*, have stood up bravely against the severe cold of the present winter. They unfortunately cast their feathers in winter, and at the present time (February) are almost without the needed feather protection. It may be that under the influence of climate a change will take place in the time of moulting, so that it will conform to that of our other domestic birds. We sincerely hope that they may prove hardy, and become fully domesticated, as they will make a fine addition to our various families of barn-yard fowls.

THE CATTLE DISEASE. — Dogs, cats, and fowls must be looked after and prevented from running at large, in those sections where the mouth and hoof disease prevails. Unquestionably, many animals have had the infection brought to them through birds and domestic animals. A gentleman of Hingham informs us that a favorite cat, in her visits to the barn of a neighbor, conveyed the disease to his herd, and they are now suffering severely from it. Every avenue through which the contagion can be propagated must be vigilantly guarded, if we would check the spread of the disease.

PEACE AND WAR.

Is it probable that the nations of the earth will ever sheathe the sword and cease to war against each other, and that all national disputes and difficulties will be settled by diplomacy or a congress of nations? In the light of past and present experience, in view of the exhibitions of the murderous spirit exhibited so palpably in the occurrences of the times, it must be confessed that there is a strong probability that wars will continue so long as human beings exist.

Twenty or more years ago, we had the honor of being selected as one of the delegates to represent this country in the great Peace Congress held at Berlin; and at that time, in the last days of a long interval of peace, it did seem as if advancing Christianity, science, literature, art, humanity, national comity, everything, was conspiring to place a ban upon war. The kings and emperors of Europe, the great statesmen and diplomatists, looked favorably upon every effort to create an overpowering public sentiment against war. The gentlemen composing the Congress in Germany were treated with every mark of respect, and a strong hope was expressed, by war-making powers at home and abroad, that the era of continued peace had dawned upon the earth. But alas! what have we seen and experienced during the past quarter of a century? Seven important wars have occurred; at least six millions of nominally Christian people have marched upon the fields of strife, and probably one and a half millions of men have fallen victims to insatiate cruel war. This is a dreadful record for a period of time extending over only a quarter of the nineteenth century. We have recently read over again an old book, *Crevier's History of the Roman Emperors*, which is the bloody record of a race of men who cursed the world by their presence. These men rioted in carnage, revelled amid the desolation of ruined cities and empires; but they were *heathen.* How much better, more humane, more open to pity, are we than the men of pagan Rome? Look at poor France at the present time, bleeding, starving, and filled with the wailings of anguished widows and orphans? What more did the cruel Romans do in their Gallic wars, what more *could* they do, than storm cities, murder and pillage the people, and place them in a condition of starvation? *O tempora! O mores!*

DANGEROUS BURNING FLUID.

THE following note has been sent to us by the President of one of the large Insurance Companies in New York, and we take pleasure in appending to it some remarks in the way of a reply: —

"DEAR SIR: — Will you not give us in the next number of the BOSTON JOURNAL OF CHEMISTRY, a practical method of dealing with the naphtha peddlers? We want to be instructed how to blow up naphtha vapor *on call.* As the matter now stands, it works in this way: we refuse permits to our customers for its use, and tell them that their policies are voided if they burn the lighter petroline distillates in lamps. We know their danger; our loss records have taught us that. But our patrons grow indignant, and send the gasoline man to convert us. Gasoline man shows 'tests.' 'The thing will burn, but you *can't* explode it. Try; I will give you a week. You know more chemistry than I do, but the *practical* question, after all, is, will this liquid or its vapor explode? I maintain that it won't, — your chemistry to the contrary notwithstanding. I submit the fluid for trial. If *you* can't blow it up, it isn't likely that it will blow up of itself. You are bound either to *show* that it is explosive, or to admit it.' Now this sounds reasonable, and is difficult to meet. The 'Gasoline' man, the 'Sunlight Oil' man, the 'Danforth Oil' man, etc., etc., are perfectly ready to admit that *other* preparations have caused accidents, — but theirs are something new and harmless; they have been 'oxygenated,' or 'chlorinated,' or 'ozonized,' or otherwise rendered non-explosive. Now there is only one way to satisfy these parties; the soundest discourse on the chemistry of the hydrocarbons won't do it — *but you must blow up their gas. That* is conclusive, and may save a murder or a fire. Unfortunately, while we have definite ideas upon the affinity of hydrocarbon vapor for oxygen, and of their behavior when brought together in the presence of flame, we do not know the proportion of atmospheric air requisite to produce detonation — nor, were we informed upon that point, would we know how to present it in the proper proportion. Can you not instruct us herein, by a description, and cuts, if need be, of a suitable apparatus?"

Reply. — As preliminary to making reply to the above, it should be remarked that a wrong impression is conveyed by speaking of burning liquids as "explosive." There is no fluid used for furnishing light that will "*explode.*" The naphthas sold by dealers and travellers through the country, under a variety of names, "oils," "fluids," "gasolines," etc., etc., will not explode like gunpowder, gun-cotton, nitro-glycerine, etc. It must be distinctly understood *that it is only the vapor which rises from the surface of the liquids, mixed with air, which suddenly explodes.* A lamp or can holding these dangerous volatile fluids *cannot explode if it is full or nearly so*, as there must be a space above the fluid filled with the vapor mixed with air, in order that any detonation may occur. The men who vend naphtha under assumed names, deceive purchasers by setting the naphtha on fire, and by turning it out and handling it in a way which seems very dan-

gerous to uninformed bystanders. They say to their victims, "See, this oil won't *explode;* I put flame into the lamp, into the can, turn it out upon the floor, burn it under all possible conditions, and it don't explode; can anything be safer than this?" This kind of experimenting is unfortunately deemed satisfactory by many, and they readily introduce the dreadful combustible into their families. Now the fact that these men are able to ignite their fluids so readily *is positive proof* of their *dangerous character;* for any liquid, so volatile as to take fire at ordinary temperatures, will supply vapor in lamps and cans which, when mixed with air, will explode like gunpowder. But it is not often that the conditions are favorable in lamps and cans for explosions, and they do not often occur. Three fourths of all the accidents which are reported as lamp explosions *are not explosions;* they are horrible burnings from the simple ignition of the fluid by the spilling of the same upon the clothing, or by the breaking or upsetting of lamps. These naphtha fluids are not so dangerous from the liability of the vapor to explode, as from the inflammability of the liquids themselves. Now remember this. The loss of life, and the loss to insurance companies from the burning of buildings, is due much oftener to the ignition of the fluid than to explosions; occasionally a genuine lamp explosion occurs, but not often, for it is difficult to have in a lamp or can just the right mixture of air and vapor. Equal parts of air and vapor will not explode; three parts of air and one of vapor give a vigorous puff when ignited in a vessel; five parts of air to one of vapor give a tolerably smart report; but to attain the highest amount of force, about eight or nine parts of air with one of vapor are required. Now, as an experiment, it requires considerable skill and experience to get up a perfect explosion with naphtha vapor, or with gasoline. We once experimented with a fluid taken from a can, the vapor of which had exploded in a lamp, killing a woman, and it required several hours before we could manipulate so as to obtain powerful detonations with the air-mixed vapor. Few business men, we think, will have the patience to conduct such experiments to a successful issue. The best vessel to employ for the experiment is made of tin, holding about a quart. It should be in the form of two short cones, soldered together at the bases, with orifices an inch in diameter at each end, closed by corks. A small "touch-hole" may be made in the middle. Into this vessel put about ten drops of the "safe oil," replace the cork, warm *slightly* and apply a match at the touch-hole. If the mixture of air and vapor is right, a smart detonation will follow, blowing out both corks, and probably throwing the vessel from the hand. But it is not often that success is met with by one or two experiments; by careful observation and the exercise of skill, considerable dexterity and success will, however, soon be acquired.

It is not necessary for officers of insurance companies, dealers, etc., to be put to this experimental trouble. They should know that any liquid which will burn readily at ordinary temperatures *is unsafe. Nothing can be added to gasoline or naphtha which will render it safe, or the vapor inexplosive.* The travelling quacks do not add anything to their liquids but cheap insoluble substances, and this they do to keep up the deception. The dangerous volatile liquids cannot be "carbonized," "ozonized," or "oxygenized," and to claim to do this is low, vulgar quackery. When any one comes before officers of insurance companies, dealers, or consumers, claiming that they have an "inexplosive oil," which is "perfectly safe," etc., and challenging a trial, let them turn a little of the fluid into a cup or saucer, and if it takes fire when touched with a match, *it certainly will afford explosive vapors, and is a dangerous agent.* After making this simple trial, as a matter of justice, call the porter or a servant, and order him to tumble the rascal into the street, or what will be better, make an arrest, and have him tried as a dangerous mountebank, a conspirator against life in the community. There is not a jury in the country but would send such an impostor to the State Prison.

This vending inflammable liquids under false names, to be used in households, is a very bad business, and should be stopped. More than *two thousand* persons were killed or dreadfully burned last year in the United States, from the use of these liquids, and this loss of life was wholly unnecessary. It resulted from the recklessness and cupidity of men who ought not be outside of prison walls. There should be no timidity or hesitation in dealing with this class of persons. An end can be put to the business in a few months, if the people will it.

ZINC POISONING.

ANOTHER case of zinc poisoning is given under our medical head. They are evidently quite common in all parts of the country. Some further comments on the remarkable Report of Dr. Winsor were prepared for this number; but as we learn that he is to appear again in defense of the galvanized pipe makers, we defer our remarks to another time. Dr. J. L. Cassels, Professor of Chemistry in the Cleveland Medical College, Ohio, makes the following statements in a Report upon the various kinds of water-pipes, prepared at the request of the Trustees of the Cleveland Water Works:—

"A series of experiments were also made, to determine, as near as possible, the action of the water on galvanized iron. The object of these was to ascertain what might be the result in using galvanized iron pipes to convey the water from the main pipe to the dwellings of the consumers. It is well known that galvanized iron is simple iron coated with zinc, which, from their electrical relations, protects the iron from corrosion. This protection of the iron, however, is at the expense of the zinc, which is thus rendered more easily acted upon by solvent agents than it would be if not thus associated with the iron.

"Although the salts of zinc are not generally ranked among the more virulent metallic poisons, yet they are undoubtedly exceedingly injurious to the human constitution. Their continued use, even in minute quantities, is followed by a series of ailments which may not be immediately fatal, but ultimately result in very serious sequences.

"These effects of zinc were demonstrated to a sad degree, a few years ago, in Lancashire, England, from the use of zinc milk-pans in butter-making. It was found that the cream separated more readily in zinc than in tin pans, as the zinc combined with the acid of the milk as soon as formed. But this salt of zinc found its way into the butter, and almost every person who used it was taken sick of a disease of a peculiar type. Many of these cases proved fatal. An analysis of the butter revealed the cause of this peculiar and wide-spread sickness. The public authorities, when the cause was ascertained, interfered and prohibited the use of zinc milk-pans under a severe penalty.

"The zinc commonly used for galvanizing iron is of a very inferior quality, a large proportion of it being old zinc; which, of course, is much mixed with other metals, such as lead, antimony, brass, etc., all of which contribute largely to the formation of soluble salts in the water. But even new zinc is seldom free from these impurities. Hence even the best of galvanized iron pipes, met with in market, must necessarily endanger the formation of soluble salts, both of zinc and other metals, which may be neither safe nor pleasant to the consumer of the water conveyed through them.

"In order to test this matter by direct experiment, 1,211.95 grains of new galvanized iron chain, such as that used in the common chain pump, were put into a pint of the water taken from the hydrant near the College, in a glass beaker, loosely covered to exclude dust. In twenty-four hours the water was of a bluish white color, and tasted distinctly of the salts of zinc. In three days a whitish sediment was observed collecting on the zinc, which was easily detached by agitation. After remaining a week in the water, a large deposit of the carbonate of zinc was formed, and the water was strongly impregnated with the chloride of zinc. Traces of lead were also detected in the water, derived, probably, from the lead impurities of the zinc. The links had decreased in weight 1.04 grains, and were heavily coated with the carbonates of zinc and iron.

"From the foregoing described experiments, I am very much inclined to the opinion that both lead and galvanized iron pipes should be, as much as possible, discarded for service pipe in our city. Although the water, when constantly flowing through either of these pipes, may not become contaminated, yet when remaining in them a sufficient length of time, there can be no question on the subject; and as it is very difficult to set exact bounds to the length of time required to produce these effects, their use must always be attended with more or less risk."

THE FELLOWS OF THE MASSACHUSETTS MEDICAL ASSOCIATION.

WE have received a copy of the new Catalogue of the members of this Society, and have examined it with much interest. It is a matter of regret that it could not have been made complete, and the full name and age of every member given. The committee of revision addressed circulars to members requesting information, and not more than one half of them met with any response. Let us have this interesting catalogue complete, and this end can be reached if every member will send to Dr. Francis Minot, No. 7 Charles St., Boston, the desired facts regarding himself and his neighbors. The age of about one thousand physicians is given, and of these nearly *one hundred have lived to be over eighty years old.* The profession seems to be distinguished for health and longevity.

Among the 3,000 names, we find that 1,075 are marked with a * as deceased. Of these the ages of 858 are given as follows:—

Between 20 and 30	34	
" 30 " 40	121	
" 40 " 50	123	
" 50 " 60	155	
" 60 " 70	154	
" 70 " 80	158	
" 80 " 90	104	
" 90 " 100	8	
100	1	858

These figures may not be exact, but they are essentially so. The oldest was Dr. Edward Augustus Holyoke, of Salem, who died 1829, aged 100. Those aged 90 and over were—

John Williams, Cambridgeport,	1846,	aged 99
Oliver Partridge, Stockbridge,	1848,	" 97

William Hooker, Westhampton,	1861, aged	94
Matthias Spalding, Amherst, N. H.,	1865, "	92
John Walton, Pepperell,	1862, "	92
Benjamin Waterhouse, Cambridge,	1847, "	92
Austin Flint, Leicester,	1850, "	90
James Thacher, Plymouth,	1843, "	90
The youngest was John Heard Manning, Ipswich, died	1837, "	24

Of the above 271 were 70 and over........31.58 per cent.
113 " 80 " "........13.17 " "

EDITORIAL NOTES.

Chloralum. — This new antiseptic and disinfectant, which is attracting so much attention in England, is a chloride of aluminium. It is claimed that solutions containing but a small fraction of *one per cent.* of this compound are sufficiently strong to preserve fish and meat which have been simply dipped therein, and then suspended in dry air. It is quite odorless, which gives it an advantage over carbolic and cresylic acids for many purposes. It has been received with especial favor by medical men, who are using it in the treatment of wounds, for arresting the fetid emanations of cancers, checking the throat lesions in diphtheria and scarlet fever, preventing suppuration, and the like. It absorbs from the air the odor of fresh paint, in a manner not yet understood; and the range of its practical applications is rapidly extending. As yet it is considerably more costly than carbolic acid, but as soon as suitable works can be erected for its manufacture on a large scale, it can be furnished at a greatly reduced price. We shall give a fuller account of it hereafter.

The "Heathen Chinee" and the Telegraph. — The extension of the electric telegraph in the Flowery Kingdom is attended with some difficulties on account of the peculiar notions of the natives, as the following extract from a recent writer may show: "A few years ago some Americans at Shanghae thought it was a good speculation to construct a telegraph line between that city and the mouth of the river. The distance was about fifteen miles, and when finished the line operated satisfactorily. The Chinese made no interference, officially or otherwise, with its construction. They did not understand its working, but supposed that the foreigners employed agile and invisible devils to run along the wires and convey intelligence. All went well for a month or two. One night a Chinese happened to die suddenly in a house that stood near a telegraph pole. A knowing Celestial suggested that one of the foreign devils had descended from the wire and killed the unfortunate native. A mob very soon destroyed the dangerous innovation."

Civilization and Health. — The interesting address on this topic, delivered by Dr. Francis Bacon, of New Haven, before the American Social Science Association, has been printed at the Riverside Press. It is characterized by sound sense and clearness of statement, and evinces much patient research on the part of the author. He does not believe in the physical or mental deterioration of mankind, but, on the contrary, shows conclusively that the race was never so healthy, comfortable, intelligent, and happy as in the present age. We may make some extracts from the address at a future day.

Huxley for a Penny. — In England they have courses of scientific lectures for workingmen at a penny each; and printed reports of the lectures, revised by the authors, are sold at the same price. A "second series" of these lectures in the Hulme Town Hall included one by Huxley on Coral and Coral Reefs, and one each by Roscoe and Huggins on Spectrum Analysis. The British workman may be very badly off in some respects, but his Yankee brother may well envy him such opportunities as these. When shall we have something like it in this country?

ATOMS.

The hog crop of 1870 is 15 per cent. less than that of 1869, but it amounts to *twenty million tons.* — Chicago sends squashes to Boston, which might at first seem like sending coals to Newcastle. — One factory in Prussia furnishes for the army 80,000 cans of preserved meat daily. — The marine losses of the United States for the past year foot up to more than nineteen millions of dollars. — The "Scientific Miscellany" is an excellent feature in the new volume of the *Galaxy*. — A spring of fresh water has been found in the rainless desert of Atacama in South America, and has been granted to the discoverer for ten years, after which it is to belong to the State. — The *Bowdoin Scientific Review*, published by Professors Brackett and Goodale, at Brunswick, Maine, is admirably edited, and ought to be more widely known. — A portion of one of our familiar articles on the stereoscope, after crossing the Atlantic and being copied by *Nature*, has come back again and appears in the *Living Age*, being duly credited by both periodicals to "The American *Journal of Chemistry*." — Somebody has calculated that New York spends $8,500 a day for bread, and $10,000 for cigars, and that the aggregate expenditure of the United States for tobacco in all forms is not less than six hundred millions of dollars. — A piece of flannel wet with turpentine, and put among woolen clothes, will keep the moths away from them. — In California poplars grow from ten to fifteen feet in a single year. — Of forty-seven Sisters of Charity employed in the Paris hospitals, eleven have died of small-pox. — A correspondent of the *Western Rural* asks how he can best propagate the locust; whereupon somebody suggests that he had better not encourage the production of the insect at all. — In Great Britain, during the year 1869, mineral wealth was dug out of the earth to the amount of $176,260,000; the heaviest item being 107,428,557 tons of coal. — It is reported that the famous tower of Pisa, which has had "a leaning that way" for several centuries, is likely to fall soon; but we are inclined to think that the tower has a better foundation than the story. — An attempt is to be made to establish a silk manufactory near New York on a larger scale than ever before in this country, French machinery and workmen being imported for the purpose. — The *American Educational Monthly*, which we are happy to add to our clubbing list, gives a broad interpretation to the "educational" in its title, and ought to be as popular among parents as among teachers. — We note quotations from the Journal in recent numbers of five London periodicals, — the *English Mechanic*, the *Popular Science Review*, the *Building News*, the *Food Journal*, and *Nature*. — It is stated, on good authority, that 20,000 persons die annually from snake-bites in British India. — The French artificial stone, known as *béton coignet*, is now made in large quantities in Brooklyn, N. Y. — The *College Courant* has shown up R. Grant White's "Words and their Uses," in a series of articles which will be worth to any teacher of the English language a good deal more than the cost of a year's subscription to that journal. — During the siege of Strasbourg the cannons were heard at Baden, fifteen miles off. — The Spanish foot is equivalent to 11.03 English inches; the Prussian, to 12.36; the Austrian, to 12.45; and the Russian, to 13.75. — The narrow gauge railway, which has been so successful in Wales, is likely to be tried quite extensively in this country and in Canada; one line being already in operation in Ohio, and a dozen others projected in that State and elsewhere. — The *Scientific American* is publishing an interesting series of articles on "Perpetual Motion," with many curious illustrations of the devices by which a perverted ingenuity has attempted, not only in the dark ages but in our own day, to achieve that mechanical impossibility. — A Mr. Silber, in London, proposes to distribute illuminating oils through towns, factories, and other buildings, as water is now distributed, the flow of the liquid being regulated at the burner by certain novel devices. — Rolfe's edition of *The Merchant of Venice* is very generally commended by the press and by practical teachers. — Ritchie of Boston has made an induction coil, which with fifty miles of wire gives a spark of 21 inches; while Professor Pepper's famous coil, which, we believe, has three times that length of wire, gives a spark of only 28 inches. — The "Chemistry" of the *Cambridge Physics* appears to be the most popular book of that series, having now reached its *ninth* edition. — Our articles on water-pipes are attracting attention, not only in England, where they have been indorsed by several scientific journals, but also in the Sandwich Islands, where the use of lead pipes, like many other vices of civilization, has been introduced, though the abomination of galvanized iron, it would seem, is as yet luckily unknown. — The *Literary World*, edited and published by Mr. S. R. Crocker, of this city, at fifty cents a year, is the cheapest literary monthly in the country, and as good as it is cheap.

LITERARY NOTES.

Wöhler's Handbook of Mineral Analysis, published by Baird of Philadelphia, and advertised in the present number, is commended by high critical authority as "the most complete collection of examples for practice in quantitative mineral analysis extant, guiding the student through the whole range of the subject, from the analysis of simple compounds to the separation and determination of the ingredients of the most complex minerals." No living chemist has accomplished more for this branch of analytical chemistry than Wöhler, and his fame has for years attracted large numbers of foreign students to Göttingen. It is said that he can reckon among his pupils more American chemists than any other European professor.

Wood's American Botanist and Florist, published by Messrs. A. S. Barnes & Co., of New York, is a model book of its class. The new Flora is noteworthy as being at once very full and very concise. In 370 duodecimo pages are recorded and defined nearly 4,000 species, including all the cultivated as well as native plants known in the Atlantic States. Nothing essential is omitted, but much space is saved by avoiding needless repetitions. Exotics are distinguished from native plants by putting their names in different type; and there are other little devices of the kind to aid the student and the teacher. The illustrations are numerous and excellent.

Life and Nature under the Tropics, by H. M. and P. V. N. Myers, from the press of the Appletons, is another of the fruits of the scientific expedition from Williams College to the tropical regions of South America. One division of the party made their way to the Amazon from the north by the valleys of the Orinoco and Rio Negro; the other crossed the continent from the west, passing over the Andes to the Rio Napo, and down that river by canoes to the Amazon, which they followed to its mouth. Professor Orton has given us an interesting account of the latter division in his "Andes and Amazon" (published by the Harpers), and the young authors of the book before us have been equally successful in their report of the other party. The work is a valuable addition to the literature of South American travel.

Counsel to a Mother, by Pye Henry Chavasse, is a neat little book published by the Lippincotts. As the author states, it is "a continuation and the completion of *Advice to a Mother*," which has been commended by the London *Lancet* and other leading medical critics, and has already reached its *ninth* edition in this country. This supplementary volume will probably be no less popular.

The third volume of the *Gynæcological Journal* (to use the generally accepted abbreviation of its un-

manageable title) has just been issued, by Mr. James Campbell, in the same tasteful style as its predecessors. Physicians who wish to have complete sets of the magazine should secure these early volumes before the edition is exhausted.

The first two volumes of the *American Journal of Obstetrics* have also been issued in bound form. As contributions to our standard medical literature, they well deserve the elegant dress given them by the publishers. No physician's library is complete without them.

The Gas Consumer's Guide, elsewhere advertised, is a very useful manual, and readable withal. Not one out of a thousand knows how to use gas economically, but this little book will enable him to do so.

☞ WE do not often print the complimentary notices with which our brethren of the press honor us, but we cannot deny ourselves the pleasure of copying the following from the *Boston Post* of January 26th, 1871 : —

" The signs of prosperity which this really excellent magazine shows are gratifying to the large number of readers to whom its monthly appearance is so welcome. It is enterprising, lively, fearless, and edited with a rare combination of scientific knowledge and popular common-sense. Its contents are of practical value in every household, and its merits hardly need the very liberal premiums which are offered as further inducements to subscribers."

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

THE *American Journal of Science and Arts*, for February, has articles on the Variation of the Magnetic Needle in connection with the Aurora, by A. M. Mayer; on Granitic Rocks, by T. S. Hunt; Siredon Metamorphoses, etc., by E. D. Cope; Lower Carboniferous Limestone in Ohio, by S. B. Andrews; Some Imperfectly Known Ascidians from New England, by A. E. Verrill; Insects Inhabiting Salt Water, by A. S. Packard, Jr.; The Nummulitic Formation in China, by Baron von Richthofen; Memoir of Thos. Graham, by J. P. Cooke; Auroral Belt of Oct. 24, 25, etc.; with more than twenty-five pages of Miscellaneous Scientific Intelligence.

Archives of Science, and Transactions of the Orleans County Society of Natural Science is a new quarterly, published by J. M. Currier, M. D., at Newport, Vt., for $2.50 per annum. We can furnish it, *with the* JOURNAL, for that price. It is to be entirely made up of original articles, especially upon scientific matters connected with Vermont, and the first number is a very good one.

The *New York Medical Journal*, for February, has original communications, by Prof. Hammond, on Diffused Cerebral Sclerosis; by Dr. R. A. Vance, on the Ophthalmoscope in the Treatment of Epilepsy; by Dr. S. G. Armor, on Catarrhal and Croupous Inflammation of Mucous Membranes; and by Dr. E. R. Peaslee, on Intra-Uterine Medication. Thirty-five pages are devoted to a valuable Report on the Progress of Ophthalmology for 1870, by Dr. H. D. Noyes, of New York.

The *Chicago Medical Journal* has the following original communications: Cases in Practice, with Remarks upon the Use of Veratrum Viride, by B. O. Reynolds, M. D.; Cases in Private Practice, by Jno. E. Owens, M. D.; Obstinate Dyspepsia Cured by the Use of Milk, by I. N. Danforth, M. D.; on Instruments for the Treatment of Uterine Diseases, by Philip Adolphus, M. D.; on Operation for Hare-Lip, by F. C. Hotz, M. D.; Cases in Electro-Therapeutics, by Wm. J. Maynard, M. D.; Cook County Hospital, by Curtis T. Fenn, M. D.; Satan in Society, by Volta Reeke.

The *American Practitioner* contains original articles on Emmenagogues, by Prof. Parvin; on a Case of Hydrocele, by Dr. G. W. H. Kemper; on Gonorrhœa Treated without Injections, by Dr. A. Given; on Subnitrate of Bismuth in Cholera Infantum, by Dr. C. K. Alexander; and on the Treatment of Granular Lids, by Dr. H. Ruschhaupt; with Reviews, etc., etc.

The *Journal of Psychological Medicine*, for January, has the following original communications: Clinical Lectures delivered at the Bellevue Hospital Medical College, Session of 1870–71, by William A. Hammond, M. D.; A Letter to the Editor on some Recent Contributions on Mental Science and Anthropology, by George Edward Day, M. D., F. R. S.; Sleep and Dreams, by Ewald Hecker; A Case of Hydrophobia, by S. G. Cook, M. D.; Buried Alive, by T. Edwards Clark, M. D.; with over a hundred pages of reviews and minor articles on the physiology and pathology of the nervous system, anthropology, etc.

The *Nashville Journal of Medicine and Surgery* contains original articles on Enchondromatous Tumors of the Hand, Fore-arm, and Arm — Amputation at the Shoulder-joint; Wound of the Peritoneum from a Stab — Recovery; Tobacco an Antidote to Malaria; New Method of Reducing Dislocations at the Shoulder-joint; Large Doses of Calomel in Uræmic Poisoning; with Editorials, Reviews, etc.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

J. FOGG, of HOLDEN, writes about his subscription. There are three post-offices of that name. We answered to Holden, Mass., but the letter has been returned to us by the Postmaster, uncalled for.

MRS. M. P. J., PORTLAND, ME. Not having had much experience with aquariums, we cannot answer your question. Cotton and linen are bleached by the same agents.

DR. F. REGNIER writes from Pekin for a sample copy. There are six Pekins. Which one is it ?

M. K. — For a long while there was some doubt as to the chemical equivalent of mercury. At first *calomel* was considered a chloride, and its formula was given as HgCl ; and corrosive sublimate was a bichloride, with the formula $HgCl_2$. Subsequently, calomel came to be viewed as a subchloride, Hg_2Cl, and corrosive sublimate as a chloride, HgCl. Under the *new* system of notation (the equivalent of mercury being 200, oxygen counted as 16) calomel is *mercurous chloride*, with the formula Hg_2Cl_2, or, as some write it, HgCl ; and corrosive sublimate is *mercuric chloride*, $HgCl_2$. Of course these changes have led to a good deal of confusion on the subject in text-books and other scientific publications.

A. B. S., CRAFTSBURY, VT. — Mercury does *not* expand upon solidifying, but contracts considerably. If a thermometer bulb bursts when the mercury freezes, it would appear to be from the pressure of the air outside, the contraction of the mercury leaving a vacuum between the metal and the thin glass. There are but few metals or alloys that expand when they become solid. Iron does, and hence it is well adapted for castings, completely filling the mould as it solidifies. Bismuth expands in the same way, and so does the alloy of lead, tin, and antimony, which is used for printers' types.

Other answers are unavoidably crowded out this month.

Medicine.

HYDRATE OF CHLORAL.

THIS important agent continues to attract much attention from medical men, and we are daily receiving communications upon the subject. We give below two recent letters from the West, and append a few remarks by way of reply.

EDITORS OF JOURNAL OF CHEMISTRY : — In your issue for January, 1871, I find an extract from a contribution of my own in the *New York Medical Gazette* for November 26, 1870, on the use of " Hydrate of Chloral in Parturition," to which are appended some remarks of your own, to which in a brief manner, I wish to advert.

Your inference that I had " put in jeopardy the lives of several patients " is hardly correct; though you doubtless have some grounds for the supposition, as the article in question was written under a misapprehension in regard to some antecedent facts, namely, that I had used the " Hydrate " but one time before, and had reported the results of that experience to the *Gazette*, in the columns of which I was then, Nov. 10, looking for its publication. The manuscript was lost in the mails. The *second* case, that of Mrs. W., from which your extract is taken, and the case of Mrs. L., the " nervous lady," are the only " several " cases in which I have ventured on prescribing the " vile, impure compound " — a nomenclature, by the way, in which I heartily con ur.

Following are the symptoms excited in my first case — the " nervous lady," to whom from 11 A. M. to 6 P. M. I had given 50 grs. of the " Hydrate," to quiet a neuralgic condition, attended for many hours before with insomnia. 11 A. M. 15 grs. in aqueous solution, followed by *severe* cephalalgia as the only noticeable result. 1 P. M. 15 grs., followed by flushed face, injected conjuctivæ, greatly intensified headache, moaning, with mutterings of grave apprehension, accompanied with a wild semi-delirious condition, analogous to that sometimes observed from the excitement of the inhalation of chloroform, or the intoxication of alcohol. About 5 P. M. supposing that I had been too timid in its employment, I returned to my office and *weighed* 20 grains, and almost with electric rapidity it exerted its action, s[o] with such alarming power that I began seriously [to] wish that the great Liebreich had kept his discov[ery] to himself. The patient's lips became livid, pu[lse] ceased to beat, the respiratory system became [in]stantly paralyzed, the whole muscular system pow[er]less; the patient's body, to use a very domes[tic] but suggestive term, was limber as a dish-rag. [In]deed, familiar as a lengthy practice had render[ed] me with scenes of danger, I was deeply concern[ed] for the patient's safety.

My first efforts were to hastily turn the pati[ent] from side to side, draw the tongue forward, da[sh] the face with cold water, etc., with the hope to re[es]tablish the respiratory functions, which I succeed[ed] in accomplishing in a short time. I could not sa[t]isfy myself as to the condition of the pupils duri[ng] the suspended animation, owing to the darkness [of] the room at the time ; but the anæsthetic conditi[on] of the cutaneous structure was very complete, [as] sharp pinching elicited no response.

After the circulatory and respiratory functio[ns] were properly reëstablished, the patient lapsed in[to] a profound sleep, from which she awoke in the mor[n]ing well as usual.

There may have been a special idiosyncrasy b[e]longing to the patient, rendering the remedy ina[p]propriate ; or the idiosyncrasy, if you please, mig[ht] have pertained to the *medicine*, and not to the p[a]tient ; however the case might have been, *I* do n[ot] " think it very strange that any physician should *ri[sk]* so much as to use a new and powerful agent whi[ch] comes into his hands," etc., as a physician is suppos[ed] to be familiar with the normal therapeutic action o[f] the remedies he prescribes ; and it is now the custo[m] for him to depend on the honesty and intelligence [of] his apothecary to supply him with the genuine artic[le] for which he calls. It is hardly expected of the ph[y]sician, at least here in the somewhat primitive We[st] to apply proper chemical tests to each remedy su[p]plied him ; and mere physical properties are unce[r]tain as to the worth of an article. Nor is the *nam[e]* of the manufacturer every time a guarantee of th[e] genuineness of the contents of the bottle, for unfo[r]tunately pharmacy has its empirics as well as th[e] profession of which I am an unworthy member.

Your very excellent JOURNAL might confer a ben[]efit on the profession of medicine, and through [it] on the general public, by publishing a simple an[d] reliable *test* by which practitioners could try th[e] properties of the Chloral before purchasing, or a[t] least before prescribing it. J. P. CHESNEY.

NEW MARKET, PLATTE CO., MO.

EDITORS BOSTON JOURNAL OF CHEMISTRY : — Just now the newspapers are warning against th[e] use of Chloral Hydrate, on the ground, that, ente[r]ing into combination with the soda of the blood, [it] tends to decompose that fluid, and leads under cer[]tain circumstances to hemorrhage !

Is this so ? and if so, can we ascertain when [it] may or may not be safe to use it ?

The question has arisen in my own mind, whethe[r] the chemical purity of the salt might not have some[]thing to do with the results. But if its chemica[l] character is allied to that of Chloroform , or if, a[s] is stated by some writers, it is changed into Chloro[]form in the system, can it be so modified as to ren[]der it safe ?

Will you please to give in the JOURNAL what i[s] *really known* on the subject, as it often happens tha[t] newspapers make loose statements, and give some[]body's surmises, rather than actual facts.

BENJAMIN WOODWARD, M. D.

WYANDOTTE, KANSAS.

Reply. — The fact that hydrate of chloral has been used extensively for a period of nearly two years by physicians in all parts of the world, and that few, if any, well-authenticated instances

'injury have been reported, is evidence that it is safe agent to employ. Dr. Liebreich has pub-ished cases where its use was continued in large ›ses for months, and the general health of the ıtients steadily improved. Physicians should ›t be turned away from the use of a medicinal ;ent of the greatest service, by any sensational ıragraphs in newspapers, or by the statements ' a class of medical men who are incompetent to ıdge correctly of the therapeutical value of any 'ug. We believe *pure* hydrate of chloral to › a safe agent in the hands of every judicious, ,nsible, educated physician. The quacks have ıfortunately seized hold of it, and flooded the 'arket with their chloral nostrums. We called tention to the various "syrups," "solutions," ıd "elixirs" of chloral, some months since, ıd stated that hydrate of chloral underwent ›ontaneous change from being kept in any ›quid form, and consequently all these mixtures ere inert or injurious. The *pure crystals* are e only form in which it should be kept, and ›m these, physicians can make their own com-ıations for the use of their patients. Large ıantities of the crystals are sold which are *ry impure*, and in response to Dr. Chesney's ggestion, we would state that when a frag-ent of pure hydrate of chloral is placed in a st tube or wine-glass with a little water, and few drops of liquor potassæ allowed to fall ›on it, no discoloration takes place, and there evolution of pure chloroform, which can be tected by the odor. If the specimen experi-ented with is *impure*, a *dark* or *brown* reac-›n will result, and the odor evolved will be ıpleasant. In this way a certain class of com-on impurities may be detected. In an article ›on this important agent, to be published soon, › shall give a more extended account of it in ı its relations.

A CASE OF ZINC POISONING.

BY IRA F. PACKARD, M. D., STURGIS, MICHIGAN.

Editors Journal of Chemistry: — Permit › to give you my experience in a case of zinc isoning, myself and wife being the victims. I ve in my house a water-cistern holding one hun-ed barrels or more. In the bottom of the cistern a filter through which the water has to pass be-e entering a small cistern, where the pump is. I en made use of a galvanized iron pipe, thirteen t in length, attached to the pump through which › procured the water used for culinary and drink-g purposes. In the spring of 1870, the first ill ects were noticed, which were manifested by a ntinuous dull pain across the forehead over the ›ntal sinuses, accompanied with extreme sensi-lity of the cartilage of the ear and nose, so se-re that the least friction or bending of the ear or e nasal cartilage would cause acute pain. Then me stiffness of the joints, with sharp, lancinating ins above the joints, always transverse, not length-ays of the limb. Pressure on the joints produced reness and pricking pains, which would last for me minutes.

This was continued until about the first of Sep-mber, 1870, when I thought the trouble might in me way be connected with the use of cistern ater. I then had my cisterns cleaned and washed, aving the zinc pipe, which on the outside did not pear to be much corroded.

We now closed our house, leaving the conduct-g pipes so as to carry the water into the larger cis-rn. We were absent one month, or until the 8th y of November. During our absence the bad symptoms nearly all disappeared, and we considered ourselves quite well.

In our absence sufficient rain had fallen to fill the cisterns more than half full, and the water appeared very pure. We now began to use the water for all purposes again; and in about one week the old pains and troubles returned with increased violence; and in addition, a severe pain in the region of the heart was experienced, with a slight swelling externally, and great tenderness over the cardiac region.

I now became convinced that we were suffering under the influence of some slow poison; and that probably it was due to the oxide of zinc found in the galvanized water-pipe. From this time we discontinued the use of the cistern water; and in a short time we both began gradually to improve in health, and now consider ourselves well, with the exception of a slight stiffness of the knee-joints.

On removing the pipe from the cistern, it was found corroded, and the zinc covering removed. The portion immersed in water was corroded in a spiral form, and so far oxidized that a portion fell off upon exposure to air.

MEDICAL MEMORANDA.

The New Anæsthetic. — The new anæsthetic, *chloræthyl*, or *æthyliden chlorid*, discovered by the distinguished Dr. Oscar Liebreich, of Berlin, the discoverer of Chloral Hydrate, is really an agent of great promise. We have during the past two months experimented with it considerably; and we find in our own case, it produces anæsthesia quickly, and is free from any unpleasant after-symptoms. It certainly produces less nausea than chloroform or ether, the insensibility is very profound, and the agent has a pleasant odor. These are important considerations. The only drawback is its high cost, it being ten times greater than chloroform. With improved methods of manufacture this objection may be overcome.

Chlorodyne. — Dr. Long, U. S. Consul at Panama, contributed to the last number of the Journal a formula for chlorodyne, which, upon more careful inspection than was given it when received, appears objectionable in several particulars. The quantity of morphia is quite too large for employment, unless in cholera, or other formidable acute diseases, and the ammonia is an incompatible agent in the mixture. It will be well to wait for explanations from Dr. Long before preparing or employing this form of chlorodyne.

The Food of the Armies. — The Germans (says the London *Lancet*) appear to be a more hardy race than their opponents. They can eat black bread, the issue of which had to be prohibited among the French prisoners on account of their inability to digest it. *En passant*, we may state that the Germans have practically managed to solve for themselves the difficult problem of an economical and compressed ration for field purposes. Their soldiers, we read, on several occasions during forced marches, consumed a diet composed of mixed peas and meat — a highly nitrogenous but not very digestible compound. The Rhine wines were always consumed where they could be procured, and we do not hear of a rum or spirit ration being issued, as in our army. The craving for tobacco exhibited by the troops, and their almost universal use of it, corroborate the opinion entertained by practical men that the consumption of tobacco is of real value to men undergoing the hardships of a campaign.

Fatigue to the Eyes caused by Artificial Light. — It is stated by M. Meunier that the great difference between sun and artificial light is due to the fact that, of the light emitted from the former, about half the quantity of rays are luminous and calorific at the same time; but, as regards our artificial light (colza oil), the amount of non-luminous, yet colorless, rays is 90 per cent.; for white-hot platinum, 98 per cent.; alcohol flame, 99 per cent.; electric light, 80, and gaslight, 90 per cent.; while for petroleum and paraffine oils, the amount is 94 per cent. It is this large proportion of calorific rays in artificial light which causes fatigue to the eyes; but this inconvenience may be almost entirely obviated, according to the author, by intercepting the thermic rays by glass, or better, by mica plates. These render the light soft and agreeable.

Rand's Medical Chemistry. — A second revised and enlarged edition of Professor Rand's excellent manual has been issued by the Lippincotts. It is fresh in its facts, though conservative in its nomenclature and notation. Until the nomenclature of the Pharmacopœia is revised, it is well enough to retain the old names in a book intended for the special use of the medical student; but we think that the new notation should have been given (even if only in brackets, in addition to the old), as it is now so extensively used by medical writers.

VALUABLE FORMULÆ.

Tonic Tooth Powder. — Triturate well together one ounce of pulverized Peruvian bark, one ounce of pulverized white Castile soap, and two ounces of the best prepared chalk. It may be flavored by adding a little of the oils of wintergreen and rosemary, with the latter in a very small proportion. This powder is not only good for the teeth, but also a preventive of, and a remedy for, spongy gums. Another very good tooth powder may be prepared by the addition of one ounce of pulverized orris root to the above. The addition of bole armenia to tooth powders is only for the purpose of coloring them, and is not of the slighest benefit. The Peruvian bark will impart sufficient color to this preparation.

Transparent Pomade. — Spermaceti, 2 ounces; castor oil, 5 ounces; alcohol, 5 ounces; melt the spermaceti and oil together, and gradually add the alcohol, stir well together, and when nearly cool perfume with a mixture of 30 drops of oil of bergamot, 15 drops of oil of lemon, 10 drops of oil of lavender, and 10 drops of oil of neroli. Any other perfume may be used, if preferred.

For Skin Affections. — Powdered starch, zinc, lycopodium, etc., are very useful in allaying the heat and itching in acute inflammation of the skin, as erysipelas, shingles, or eruptions attended with moisture. The following is an excellent prescription containing camphor, which is an important adjunct: —

℞.	Powdered starch . . .	dr. vj.
	Oxide of zinc . . .	dr. iij.
	Powdered camphor . . .	dr. ss.
	Cochineal	gr. j. M.

To be kept in a stoppered bottle, to prevent evaporation.

Lip Salve. — Take of

Spermaceti, ...	one ounce.
Yellow wax, . .	half an ounce.
Oil of almonds, . .	two ounces.
Oil of rose, . .	twelve drops.

Melt with gentle heat, add alkanet root, q. s., to color, then strain, and lastly add the oil of rose.

Tooth Wash. — Take of

Soap tree bark, in powder, two ounces.
Orris root, in powder, one ounce.
Canada snake root, in powder,
Cloves, in powder, of each half an ounce.
Alcohol, ten fluid ounces.
Water, five fluid ounces.
Honey, two ounces.

Mix the alcohol and water, and exhaust the powders by the process of percolation, add the honey to the percolate, and filter through paper.

Pills of Sandal-wood Oil. — The Chicago *Pharmacist* says: "On several occasions we have been requested by physicians to prepare pills from the oil of yellow sandal-wood, each containing from

five to ten drops. This we have accomplished to the satisfaction of both prescriber and patient, by the following method: —

Take of Oil of Yellow Sandal-wood,
Yellow Wax, each, half a troy-ounce.

"Melt the wax in a capsule, and weigh into it the oil of sandal-wood; mix and stir until cold, then roll out the mass, and divide it into 80 pills, by means of the pill-machine or pill-tile, in the same manner as an ordinary mass, and sprinkle with marsh-mallow root powder. Each pill contains three grains, or about five drops of the oil. The excipient is unobjectionable, as it is readily soluble in the juices of the stomach. In the same manner we have made pills of the oils of cubebs, black pepper, and fleabane."

Rose-water. — The following is from the same authority: "When rose-water is prepared from the oil by rubbing with magnesia, and adding water, a certain loss of oil occurs (absorbed by the magnesia), and the resulting water will not give clear solutions with nitrate of silver, owing to the solution of a minute quantity of the carbonate of magnesia, or of saline matters contaminating the latter, or both. A better method, and which of course yields a pure product, is to drop the oil into boiling distilled water, and incorporate by agitation. Other medicated waters may be prepared in a similar manner."

A REMEDY FOR ASTHMA.

Dr. James S. Bailey, of Albany, says in the *Medical Record*: Having during the last fifteen years prescribed many remedies with indifferent and uncertain success, after much careful study I have prepared the following formulary, which has, during more than half this period, acted to my entire satisfaction. I now place it at the disposal of the profession, hoping it may meet with the same success in their hands as in mine, in relieving the distress of this unfortunate class of sufferers: —

℞	Syrup of tar compound	oz. iv.
	Sulphuric ether	oz. ii.
	Pulv. gum acacia	drs. vi. M.

Take one teaspoonful every two or three hours until relieved. Oftentimes two or three doses are quite sufficient to relieve an aggravated attack of spasmodic asthma.

As the syrup of tar compound is my own preparation and not pharmaceutical, it is necessary to give the formula for its preparation: —

℞	Picis liquidæ	oz. iv.
	Scillæ acet.	O. j.
	Antim. et potass. tart.	grs. xvi.
	Magnesiæ carb.	oz. ss.
	Sacch. albi	oz. xxx.
	Sulph. ether	
	Spts. vini rectificati, aa	f. oz. j.

Mix the tar and carb. magnesiæ intimately in a mortar, adding the alcohol first and then the ether, then add the acet. scillæ and throw the whole upon a stout filter. Having added sufficient acet. scillæ (if may be) to make the filtered liquid measure O. j., proceed to make the syrup by the usual U. S. P. formulary, taking care to apply a gentle heat. Lastly, strain through flannel and add the tart. antimonii in solution.

After the paroxysm is relieved, the patient is left in a relaxed and debilitated condition; it is then necessary to resort to a tonic course of treatment. A generous diet, with simple bitters or mild preparation of iron, is generally sufficient to restore the system to its accustomed health.

COLORED FIRES.

Druggists are occasionally required to furnish colored fires; and though we know that there is no lack of formulæ for their preparation, we suppose that the source from which the following recipes are derived is some guarantee of their superiority. The formulæ were presented to the Physical Society of Frankfort by a member of the German artillery corps: —

1. White light: 8 parts saltpetre, 2 parts sulphur, 2 parts antimony.
2. Red light: 20 parts nitrate of strontia, 5 parts chlorate of potash, 6½ parts sulphur, 1 part charcoal.
3. Blue light: 9 parts chlorate of potash, 3 parts sulphur, 3 parts carbonate of copper.
4. Yellow light: 24 parts nitrate of soda, 8 parts antimony, 6 parts sulphur, 1 part charcoal.
5. Green light: 26 parts nitrate of baryta, 18 parts chlorate of potash, 10 parts sulphur.
6. Violet light: 4 parts nitrate of strontia, 9 parts chlorate of potash, 5 parts sulphur, 1 part carbonate of copper, 1 part calomel.

CARBOLIC ACID AS A REMEDY FOR CARBUNCLE.

The following is from an article by Dr. J. C. Nott, of New York, in a recent number of the *N. Y. Medical Journal*: —

My attention having been attracted recently by several articles in the medical journals on the anæsthetic effects of carbolic acid when locally applied, I determined to test the remedy in a case of carbuncle which came under my care a few weeks ago. All the methods of treatment usually recommended had proved unsatisfactory in my hands, I never having seen carbolic acid recommended for this malady; and, seeing no good reason why it should promise better results, I used it without faith, and more with the idea of doing something to amuse the patient, while Nature worked the cure, than with any expectation of doing good.

A gentleman of respectability and good habits, about fifty years of age, had suffered severely, within the last twelve months, with carbuncles on his back, which had been prescribed for by another surgeon. When sent for I found a carbuncle, with several small honeycomb openings in the centre, and surrounded by the usual inflammation and hardness, covering a space about the size of the palm of my hand. It was very painful, presented all the characteristics of a severe carbuncle, and I thought the patient would make a good escape if he got off with a slough as large as a silver dollar. The tissues seemed to be so deeply involved that I could not conceive that the result would be otherwise. I made a deep incision into it about an inch and a quarter, and stuffed it with cotton saturated with the pure carbolic acid. I also painted over the whole surface of the hardened mass with the acid. The patient complained of a sharp, burning sensation for a few minutes, when the pain subsided completely. The cuticle, by the next day, came off, and the surface looked like a burn.

After the first few minutes he was free from pain, and never complained of any afterwards. I continued every day for a week to insert the acid, in the same way, into the cut, which sloughed all around to the depth of one eighth of an inch; the surrounding inflammation and induration subsided rapidly, and in a week there was nothing left to treat but the small open wound made by the knife and acid. Three other small carbuncles commenced, an inch or two from the large one; they were all treated by incision and the acid, and they all aborted.

There was, I think, something more than a mere *caustic* effect from the acid in this case. I have used incisions and caustics very often before, but this was the only real abortion of a carbuncle I ever saw. There was, I think, clearly some specific action. We know that a process of embalming has been recently introduced into this city, by which bodies are preserved by *simply sponging* them over freely with carbolic acid. It permeates the tissues in some way, so as to preserve the deep-seated as well as the superficial tissues for an indefinite time and it is only by some process of this kind that I can account for its influence on the surrounding tissues when inserted into the centre of a carbuncle th inches in diameter.

SMITH'S UNIVERSAL MEDICINES.

John Smith is ubiquitous; he turns up in the most remote and unheard-of places, and is engag in all sorts of business. Recently he has taken humbugging the people, and has chosen a first r field in which to work successfully and reap to hi self large profits. Would you believe it? John h set himself up in the quack medicine business! has opened a shop in fact, and intends dealing cure-all medicines to the waiting thousands, who only too anxious to avail themselves of John's me cal skill. John has located himself in Syracuse t time, and hails from some wonderful instituti dubbed the "New York Medical University," whi is claimed to be located on the corner of Clint Place, in New York. This establishment, Jo claims, has cured 26,340 patients in one year! O think of that, invalids! John has very graciou opened a branch office of this wholesale-curing esta lishment at No. 89 Warren Street, Syracuse, a offers to cure anybody or anything, by wholesale retail, who will send him from five to ten dollars his Universal medicines. John advertises liberal knows the advantage of printers' ink, and uses unsparingly. John is a *chemicopathic* physician a surgeon, which shows that he is shrewd in his sele tion of a name; chemicopathic is good, very goo much better, we fear, than John's University me cines. John is down on all other kind of docto and gives them particular fits in the various "su plements" which he issues to the different count papers throughout the State. This is a good tra in John — it convinces every one who reads the that John is right, and understands his business, f what John can't cure, it is useless for any oth member of the Smith family to waste time upon.

It is needless for us to wish John success — he wi certainly have it. People *will* be humbugged, a we suppose John might as well do it, with his "Un versity medicines," as any one else. It is a firs class way for people to waste money and trifle wi disease, and we recommend all in search of such i nocent amusement to apply to "Dr. John E. Smit of the Syracuse wholesale branch of the New Yor Medical University," and dispenser of the cure-al heal-over-recuperating-medico-quacko-*chemicopath* University medicines. — *The Bistoury.*

A New Styptic. — Dr. Ehrle describes a simpl preparation of cotton, which he has found of grea service in surgical operations followed by great eff sion of blood. American cotton of the best qualit is cleansed by boiling it for an hour in a weak solu tion of soda (about 4 per cent.), then repeatedl washed in cold water, and dried. By this proces it will be perfectly disinfected and adapted to mor ready absorption. After this it should be steepe once or twice, according to the degree of strengt required, in liquid chloride of iron, diluted with on third water, pressed, and thoroughly dried in the air — *neither in the sun nor by the fire*, — then lightl pulled out. The cotton so prepared will be of a yellowish-brown color. It must be kept very dry as it is affected by the damp. Lint may be simi larly treated, but the fine texture of the cotton ren ders it preferable. When placed on a fresh wound it causes a moderate contraction of the tissue, and gradually coagulates the blood in and beyond the injured veins, thus closing the source of the effusion. This property of the chloride of iron is increased by the dryness of the cotton and the extended surface offered for the development of the chemical action.

Boston Journal of Chemistry.

VOLUME V. BOSTON, APRIL, 1871. NUMBER 10.

Familiar Science.

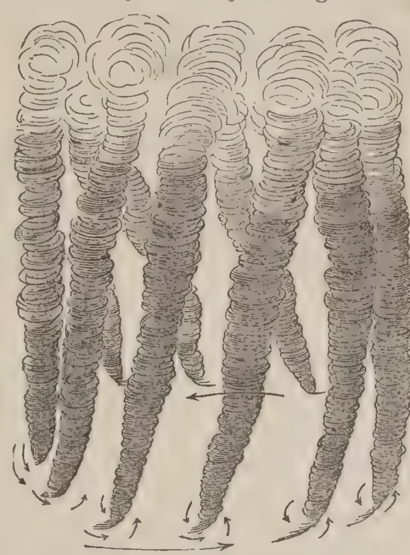
WHIRLWINDS AND DUST-STORMS.

OUR ordinary storms are virtually whirlwinds, as will be evident from a brief account of their origin. When the air over a large extent of country becomes excessively heated, it rises, and the air from all the surrounding region flows in to supply its place. But the atmospheric currents thus set in motion do not converge directly to the centre of the district where the disturbance takes place. Their motion is modified by the rotation of the earth on its axis, so that it becomes a spiral, tending gradually towards the centre. Sometimes the centre of this whirling of the winds remains stationary, but generally it moves forward, — in the United States, in an easterly direction. This progressive motion of the storm as a whole must not be confounded with the spiral motion *within* the storm. While the former is steadily eastward, so that the storm at Boston begins about twenty-four hours later than at St. Louis, and will take about another day to reach Newfoundland, the winds *inside* the storm have every possible direction at different points in their spiral path.

The rain or snow is caused by the cooling of the ascending current of air, and the consequent condensation of its moisture. As our readers are aware, the amount of moisture which air can hold depends upon its temperature; the hotter it is, the more watery vapor it can hold. If it contains all, or nearly all, the moisture it is capable of holding, and the temperature falls considerably, a part of that moisture must be condensed and precipitated.

Whirlwinds, properly so called, differ from storms in several particulars. They seldom last longer than a minute, and sometimes only a few seconds. They are equally limited in the space over which they extend, being from twenty to a few hundred yards in breadth, and seldom sweeping over a course of more than twenty-five miles. While they last, moreover, the changes of the wind are sudden and violent; and the direction of their whirling is not uniform, as in the case of an ordinary storm (which, as we have said above, owes its spiral motion to the earth's rotation), but depends upon the direction of the stronger of the two winds that give rise to them. Thus, if a whirlwind be produced by the rushing of a north wind against a south wind, the former being the stronger and to the westward, the whirl will be from left to right, or as the hands of a watch move; but if the south wind be the stronger, the whirl will be in the opposite direction.

Whirlwinds often occur in tropical countries during the hot season, especially in flat, sandy deserts. These become unequally heated by the sun, and numerous ascending columns of air are thus set in motion. In their contact with each other these ascending currents give rise to eddies, and thus produce whirlwinds which carry up with them clouds of dust. The *dust-storms* of India are whirlwinds of this description, and are illustrated by the subjoined figures. In the



first, the large arrows show the rotation of the whole whirlwind round its axis, while the small ones show the rotation of each column round its own axis. The other figure shows the general appearance of a dust-storm as seen from a distance. The storm generally comes on without warning from any direction, and the barometer

is said not to be perceptibly affected by it. A low bank of dark cloud is seen in the horizon, which rapidly increases, and almost before the spectator is aware, the storm bursts upon him, wrapping everything in midnight darkness. An enormous quantity of dust is whirled aloft, which is sometimes broken into distinct columns, each whirling on its axis. Violent gusts or squalls succeed each other at intervals, which gradually become weaker; and, at the close of the storm, a fall of rain often takes place.

In one of Lady Barker's letters from India there is a graphic account of a dust-storm. As soon as the natives perceived the signs of the coming whirlwind, the most active preparations were made to meet it. The tent-pegs were driven down more firmly, everything movable was hurried under shelter, and candles lighted in the tents. The horses were led to the lee-side of the tents, and servants stood by their heads, holding tight by the halters. The drivers of the camels made the creatures kneel with their backs to the approaching storm, and they themselves crouched close under the lee of the camels. But we will let Lady Barker continue the narrative in her own way: —

"Scarcely had the servants fastened firmly to the ground the large curtain which formed our tent-door, and which was generally festooned back with green wreaths of mango-leaves, when the tent shook and swayed backwards and forwards, and in a few moments everything was covered, more than an inch deep, with the finest dust, which had filtered through the numerous folds of the canvas. It was impossible to read or work; the candles only gave a little gleam of light through the thick atmosphere, and all we touched was gritty. For four long hours our imprisonment lasted, and it was not until sunset that the servants pronounced it safe to release us. As soon as the tent-flaps were lifted up, we all burst out laughing at each other, — such objects you never saw! No one had an eyebrow or an eyelash to be seen; the bronzed and red complexions which out-door life had produced were all hidden under a thick coating of dust, and we needed only a few streaks of paint to have looked like Clown in the pantomime, for our faces were quite as white as his. We could see the dense cloud moving on to the south-west, but all was beautifully clear behind it; only a slight haze between us and it showed that the atmosphere was not quite free from dust a little beyond us. I looked at the horses, they were all as white as if they had been powdered with flour; and the water-carriers were very busy filling the large goat-skins which serve them as water-jugs, to give every live thing which had been outside a good drink, and to wash the dust out of their eyes and ears. The camels had buried their noses in the sand, and did not appear to have suffered at all."

PYROPHORI, OR MAGICAL FIRES.

A LITTLE knowledge of chemistry enables one to perform feats that rival the wonders of the Arabian Nights. Indeed, chemistry is magic, just as the ancient magic was often nothing more than chemistry. In those days, the man who had discovered a few simple reactions, and was shrewd enough to keep the secret to himself, had all the capital necessary for setting up as a wizard or enchanter. The modern school-boy, with a few cheap salts and such apparatus as the kitchen cupboard may supply, can outdo all the marvels of those jugglers of the olden time.

A favorite performance with magicians used to be the instantaneous production of fire. A common friction match would have seemed an enchanted wand in the hands of one of those worthies. That piece of magic is too familiar to need explanation, but there are others of a similar kind not so well known to unscientific people. Liquids can be poured from bottles, or dry powders shaken from a box, that burst into a blaze as they fall through the air. *Cacodyl*, as it is called, — or *arsendimethyl*, if you prefer that name for it, — is such a liquid. It is a compound of arsenic, carbon, and hydrogen, very poisonous and ill-smelling, and not easy or safe for inexpert persons to make. *Triethyl stibine*, made up of carbon, hydrogen, and antimony, is another liquid of the kind; and there are several of the same class, in which boron, zinc, etc., take the place of the antimony. But with such spontaneously inflammable liquids we advise the reader to have nothing to do; nor with bad kerosene, which is almost as combustible and quite as dangerous.

What are known as *pyrophori* (from a couple of Greek words meaning *fire-bearing*) are solid substances, and may be safely made and used by persons of ordinary discretion. The *lead pyrophorus* is a good example of these compounds. To prepare it, fill a small bottle or test-tube one third full of tartrate of lead, place it upon a sand-bath (which you can extemporize by filling any small iron or earthen vessel with sand), and heat it as long as any fumes escape. It must then be corked tightly, and set aside to cool. It can be kept for any length of time thus corked up, but if you open the bottle and shake out the contents upon an old plate or a hearth, they take fire and burn with a reddish flame. The tartrate of lead you can make for yourself, by mixing solutions of sugar of lead (acetate of lead) and tartaric acid. Dissolve five parts, by weight, of sugar of lead and two parts of tartaric acid. Wash with water the white powder that is precipitated on mixing the solutions, and dry it thoroughly in the air, or by a very gentle heat.

Another pyrophorus may be made by mixing powdered sulphate of potash with half its weight of lamp-black, and heating it in a covered crucible. The sulphate is thus reduced to sulphide of potassium, which remains in a finely divided state, mixed with the residuum of carbon. The mixture must be kept from the air, as in the other experiment, until you wish to burn it.

Still another compound of the kind may be prepared from three parts of alum and one of sugar, dissolved in water, and then evaporated to dryness and treated in the same way as the tartrate of lead.

Now what is the chemical "moral" of these little fire-making tricks? In two words, rapid oxidation. In each case, the oxygen of the air seizes upon something in the mixture with such avidity that light and heat are evolved, or, in other words, it takes fire. But in order that the oxidation may be so rapid, the substance must be in a very fine powder, finer than you can make by any mechanical process. Many of the metals, as iron, lead, and nickel, will take fire spontaneously when in this minutely divided state; and it is lead that burns in the first experiment. When the tartrate of lead (a compound of carbon, hydrogen, oxygen, and lead) is heated, the hydrogen and oxygen and a part of the carbon are driven off in the form of carbonic oxide and water, and there remains behind a mixture of lead and carbon in powder so fine that it will burst into a flame as soon as oxygen gets access to it. The sulphide of potassium takes fire spontaneously in a similar way from the rapid absorption of oxygen. The third form of pyrophorus mentioned is essentially like the second. The alum — a so-called "double salt" — is a sulphate of potash and alumina; and the sugar is a compound of oxygen, hydrogen, and carbon, which last is left after the heating. It is hardly necessary to state that the fine powder is oxidized more rapidly than larger masses, simply because it exposes a greater surface to the action of the gas.

Thus the blaze that we make for sport serves to throw light upon some of the properties of oxygen. We see how intense is its affinity for certain substances on which it acts but feebly under ordinary circumstances; and how light and heat are evolved by the clashing of the atoms in this violent combination, just as they are by the striking together of steel and flint.

ANTOZONE.

ANTOZONE (*anti-ozone*, or the opposite of ozone) appears to be produced at the same time with ozone, whenever the latter is formed. Some chemists, indeed, believe that ordinary oxygen may be viewed as a compound of these two modifications of the element, and that under certain circumstances it can be decomposed, and the two constituents obtained in separate form. On the whole, this seems to be the most plausible theory of the relations of these three kinds of oxygen to one another.

Antozone may be obtained, separate from ozone, in various ways. If dry air, through which electric sparks have been sent, be passed through a saturated solution of iodide of potassium in water, all the ozone that has been formed will be absorbed, and the antozone will be left behind.

A portion of the oxygen in certain compounds appears to exist as ozone, while in others it is antozone. Permanganate of potash is an example of the former, and ozone may be obtained from it by the action of sulphuric acid. Put three parts of the concentrated acid into a bottle, and add two parts (by weight) of the pure dry permanganate, finely pulverized; ozone will be given off at once, and will continue to be evolved for a long time.

Peroxide of barium, on the other hand, is an example of a compound in which the oxygen — or a portion of it — appears to be antozone, which may be obtained by a process similar to that just described. Put a little concentrated sulphuric acid into a bottle, and add pure peroxide of barium in small fragments. There will soon be an evolution of gas, and the air in the bottle will be found charged with antozone. Sometimes the bottle must be heated to 120° or 140° F., before the gas is set free, while at other times it may be evolved so rapidly at the ordinary temperature that it is necessary to check the action by putting the bottle in cold water.

There is a variety of fluor-spar found in Bavaria which on being rubbed emits the characteristic odor of antozone. If the mineral be ground up with water, antozone is set free, and is absorbed by the water.

Antozone, like ozone and ordinary oxygen, is a colorless gas. It has an odor somewhat like that of ozone, but more disagreeable. It is much less permanent than ozone, changing to common oxygen quite rapidly at ordinary temperatures, and instantly when heated. It is not easy to keep it unchanged for more than an hour, while ozone, with proper precautions, may be kept for months.

One of the most remarkable characteristics of antozone is the property of forming fogs or clouds with water. It has been thought that the formation of mist and cloud in nature may be often, if not always, due to the presence of antozone in the air; but further investigation will be necessary before the question can be settled. It is certain that if air charged with antozone be passed through water, it comes out in the form of a thick white mist. When electrized air or oxygen is mixed with moist air, a similar mist appears; but the effect will be more marked if the ozone has been removed by means of iodide of potassium. The thick mist obtained by the process first mentioned may be poured from one vessel into another. If conducted through a tube into a dry bottle, it will displace the air, and the boundary between the two will be sharply defined. If the bottle be nearly filled with the mist and then closed, the mist gradually becomes thinner, and in half an hour or more wholly disappears. The water which the antozone had taken up will be deposited on the side of the bottle in little drops, and the antozone itself will have become ordinary oxygen.

It is pretty certain that both ozone and antozone are produced in all processes of oxidation and combustion. Most of the ozone unites with the body burned, while the antozone remains free or combines with water. In cases of slow combustion, antozone is produced in abundance, and, if moisture be present, forms the characteristic mist. We have examples of this antozone mist in tobacco smoke, in the gray smoke from chimneys, and in that of gunpowder. It appears also in the white fumes produced by the slow oxidation of phosphorus in moist air; and when phosphorus is burned rapidly in air or oxygen, the antozone cloud remains after the oxides of phosphorus have been completely absorbed by water.

It is well known that if this latter experiment be performed in a close vessel, the phosphorus, though it has so strong an affinity for oxygen, will not take up all that may be present. A residuum of oxygen is always found after the phosphorus has ceased to burn. The most plausible explanation of this singular result is, that the phosphorus cannot combine with antozone, but only with ozone; so that after it has burned up all the latter, the former is left unconsumed.

Antozone not only takes up water in the way that we have described, but often combines with it chemically to form peroxide of hydrogen. This reaction can be brought about in various ways, which it would exceed our present limits to describe. In this respect antozone is radically different from ozone, which has no such action upon water. It is probable that in the peroxide of hydrogen, as in the peroxide of barium, one of the atoms of oxygen is in the form of antozone. Certain other peroxides, as those of potassium, sodium, and strontium, have the same peculiarity, and they have therefore been classed together

under the name of *antozonides*. On the other hand, certain oxides — the peroxide of lead and the binoxide of manganese, for example — are supposed to contain an atom of ozone, and are called *ozonides*. When an ozonide is mixed with an antozonide, mutual decomposition takes place, the two active forms of oxygen disappear, and common oxygen is set free. It will be readily seen that this favors the theory mentioned above, that common oxygen is a compound of ozone and antozone. Several of the most important tests for antozone depend upon this action of ozonides and antozonides on each other.

Some of these tests it was our purpose to describe, but the length to which this article has already extended forbids. We may revert to the subject at some future time.

HOW WE GO TO SLEEP.

The immediate antecedents of sleep — as languor, a sensation of weight in the upper eyelids, partial temporary relaxation of certain muscles, as shown by the nodding and dropping of the head upon the breast, comparative obtuseness to external impressions, yawning, etc. — call for no very special remark. The order in which the muscles lose their power is, however, deserving of a passing notice. The muscles which move the arms and legs usually become relaxed before those which support the head; and the latter before those which maintain the body in an erect position. There are, however, many exceptions to this rule, as may be seen in church on a hot Sunday, when some of the congregation are almost certain to be seen with their chins quietly resting on their chests, but yet tightly grasping their prayer-books. Moreover, in relation to the special senses, that of sight is first lost, the closing of the eyelids setting up a barrier between the retina and the external world; but, independently of the eyelids — if they have been removed by the surgeon, or cannot be closed through disease — the sight is still the first sense whose function is abolished. Some animals, as the hare, do not shut their eyes when asleep; and in cases of somnambulism the eyes remain open, although the sense of sight is temporarily lost. The other senses, as Dr. Hammond tells us, are not altogether abolished; but their acuteness is much lessened. Taste is the first to disappear, and then smell; hearing follows; and touch is the most persistent of the senses. So, conversely, a person is most easily awakened by touch, next in order by sound, and then by smell.

ABSORPTION BY ROOTS OF PLANTS.

We have been taught by the botanies and agricultural chemistries that the food of plants is taken up in a soluble state by the porous, spongy tissue at the tips of the roots. The peculiar structure of these tips has been carefully pictured, and regarded as a beautiful instance of the adaptation of parts to their uses, of structure to function. But all this turns out to be a mistake, and illustrates anew the danger of reasoning in such matters in advance of experiment. Because the structure of these spongioles, as they are called, resembles sponge, which sucks up water so greedily, the fact that they are the true mouths of roots was looked upon as settled. Recent experiments, however, have shown that where these spongioles are the only parts of roots supplied with water, plants wither and die; while, on the contrary, if they are cut off, and the lower half of the root left in water, the plant continues fresh and vigorous. Further experiments have shown that the seat of absorption is in those parts of roots that are covered with fine hairs, called root hairs. They are mere tubular extensions of the external root-cells, and are usually invisible without microscopic aid. It is to the newer parts of roots, where these hairs are young and active, that the soil adheres with remarkable tenacity; while the growing tips, which have not yet put forth hairs, are seen to be quite clean of the soil when plants are pulled up by the roots. It has been observed that these absorbent hairs are more abundant in poor than in good soils. The roots of those plants which are destitute of hairs have a highly absorptive cuticle and numerous rootlets.

NOTES ON HOME SCIENCE.

Willow Leaves for Yeast. — A correspondent of the *Journal of Agriculture* states that the leaves of the common basket willow (*Salix nigra*, Marshall) make an excellent yeast, if treated in the same way as is usual with hops. "The discovery," he says, "was made in my family last summer, and after a thorough trial I was convinced that there is nothing equal to it, as it rises much quicker than hops — in half the time — imparts none of that hop flavor so disagreeable to some, and in fact makes better bread in every way. The thing is well worthy the attention of every good housewife; and lest some should hesitate in consequence of not knowing the medical properties of the willow in question, I will add that it is a healthful tonic, from which no harm can possibly arise."

A New Way to Cook Meat. — A good way to cook meat is to seal it in a vessel hermetically tight. Cooked thus a long time in its own juices, it is rendered very tender, and has a peculiar, appetizing flavor.

Take an earthen jar that will stand heat, with tight fitting cover. If beef is to be the dish for dinner, cut it in convenient pieces, lay them in the jar, rub each piece with salt and pepper and a little lump of sugar, and put in a little water; then lay on a piece of thick buttered paper, and press down the cover. If you think it will allow any steam to escape, mix shorts or rye meal with water to a paste; press strips of this all round the edge of cover. Bake in a moderate oven four or five hours, according to tenderness of meat. Chickens or turkeys are excellent cooked in this way. The toughest meat is rendered tender by this process; and none of the nutritious matter is wasted, as in many of the forms of cooking.

Curing Meat. — The following method has been thoroughly tested, and always proved satisfactory: To one gallon of water add one and a half pounds of salt, half a pound of sugar, half an ounce of saltpetre, half an ounce of potash. In this ratio the pickle can be increased to any quantity desired. Let these be boiled together until all the dirt from the sugar rises to the top and is skimmed off. Then throw it into a tub to cool, and when cold, pour it over your beef or pork, to remain the usual time, say four or five weeks. The meat must be well covered with pickle, and should not be put down for at least two days after killing, during which time it should be slightly sprinkled with powdered saltpetre, which removes all the surface blood, etc., leaving the meat fresh and clean. Some omit boiling the pickle, and find it to answer well; though the boiling purifies the pickle by throwing off the dirt always to be found in salt and sugar.

Cleansing Varnished Paint. — In cleansing paint which has been varnished, there is nothing better than weak tea. All the tea leaves from several drawings should be saved and boiled over early in the morning of the paint-cleansing day. If boiled in an old tin pail or pan, the tea can easily be strained off for use. Wet a flannel in it and wipe the oak-grained paint, and you will be surprised at its brightness. No soap is needed, no milk; the tea is the most capital detergent ever invented. Wipe the paint dry with a soft cloth; you will find that very little elbow-grease is needful. White varnished paint is cleansed as rapidly with it as the grained.

HOUSEHOLD RECIPES.

Protection against Moths. — A correspondent of the *Cabinet Maker* (an interesting and valuable journal, by the way) gives the following recipe as one which has kept the moths out of a furniture warehouse for ten years past: —

"Flour of hops, one drachm; Scotch snuff, two ounces; gum camphor, one ounce; black pepper, one ounce; cedar sawdust, four ounces. Mix thoroughly, and strew, or put in papers, among the goods."

To Wash Silk. — Half a pint of gin, four ounces of soft soap, and two ounces of honey, well shaken. Wet a sponge with this mixture, and rub the silk, which should be spread upon the table. Then wash it through two waters, in which put two or three spoonfuls of ox-gall, which will brighten the colors and prevent their running. Do not wring the silk, but hang it up to dry, and while damp, iron it. The lady who furnishes this recipe says she has washed a green silk dress by it, and it looks as good as new.

To Make Embroidery Patterns. — The traced patterns for embroidery are printed, when many copies of the same pattern are required. When a few are needed, they are made by hand, as follows: The drawing is made upon paper; then lay the drawing upon an even cloth, and perforate all the lines with a fine needle, close and even. Then take finely powdered charcoal, three parts, resin one part in fine powder; mix and tie it in a piece of porous calico, so that it forms a dusting bag. Lay the perforated drawing upon your material, hold down with one hand, rub the dusting bag over the drawing; the dust will fall through the holes and form the drawing on the material. Remove the paper drawing, lay blotting paper over the dust pattern, and go over it with a warm flat-iron. The heat will melt the resin and fix the drawing.

Wash for Cleansing Silver and Britannia Ware. — Take one pound of common hard soap, three table-spoonfuls of spirits of turpentine, and half a tumbler of water. Allow the soap to dissolve; then boil ten minutes, and before it cools add six table-spoonfuls of spirits of hartshorn. Make a suds of this preparation, and wash the silver with it.

To Iron Velvet Ribbon. — Dampen the under side slightly, and draw it backward and forward over a hot stove-pipe until the velvet is quite dry. A still better plan — though in winter it is not always as convenient — is to lay a wet piece of cotton cloth on a hot flat-iron placed upside-down, and while the steam is rising from it, to draw the under side of the velvet tightly backward and forward over the wet cloth.

To Make Leaven. — Stir corn meal in a pint of fresh buttermilk; add an old yeast cake dissolved in water; make it about the consistence of batter bread, and set in a warm place to rise. When well risen, add more meal, make it into cakes, and dry in the shade.

To Remove Acid Stains and Restore Color. — When color on a fabric has been accidentally or otherwise destroyed by acid, ammonia is applied to neutralize the same, after which an application of chloroform will in almost all cases restore the original color. The application of ammonia is common, but that of chloroform is but little known. Chloroform will also remove paint from a garment or elsewhere, when benzole or bisulphide of carbon fails.

The cuts on our first page are copied from the chapter on "Meteorology" in Rolfe and Gillet's *Natural Philosophy*.

A LIBERAL EDUCATION.

THE following striking passage is from Prof. Huxley's "Lay Sermons:" "That man, I think, has had a liberal education who has been so trained in youth that his body is the ready servant of his will, and does with ease and pleasure all the work that as a mechanism it is capable of; whose intellect is a clear, cold, logic-engine, with all its parts of equal strength, and in smooth, working order; ready, like a steam-engine, to be turned to any kind of work, and spin the gossamers as well as forge the anchors of the mind; whose mind is stored with a knowledge of the great and fundamental truths of nature and of the laws of her operations; one who — no stunted ascetic — is full of life and fire, but whose passions are trained to come to heel by a vigorous will, the servant of a tender conscience; who has learned to love all beauty, whether of nature or of art; to hate all vileness, and to respect others as himself. Such an one, and no other, I conceive, has had a liberal education; for he is, as completely as man can be, in harmony with nature. He will make the best of her, and she of him. They will get on together rarely: she as his ever beneficent mother, he as her mouthpiece, her conscious self, her minister and interpreter."

The Arts.

MEMORANDA IN THE ARTS.

ARTIFICIAL EBONY. — In ancient times sea-weed was a synonym for worthlessness; but modern science has found many valuable uses for this good-for-nothing product of the waters. One of the latest ways in which it has been utilized is in the manufacture of artificial ebony. The process consists in first treating the plants for two hours with dilute sulphuric acid, then drying and grinding them up. To sixty parts of this product, five parts of liquid glue, five parts of gutta percha, and two and a half parts of india-rubber are to be added, the latter two being first dissolved in naphtha. Afterwards ten parts of coal tar, five parts of pulverized sulphur, and five parts of pulverized resin are added, and the whole heated to about 300° Fahr. When cooled, a mass is obtained which in color, hardness, and capacity for receiving a polish, resembles ebony, and is much cheaper. This material is now made on a large scale, and used for nearly all the purposes to which genuine ebony can be applied.

NEW MAIL LOCK. — They are now making at Colt's factory a new patent lock for the United States mail bags. When fastened, a numbered plate of glass covers the key-hole, and this glass has to be broken before the bag can be unlocked or the lock tampered with. It is said to be the most complete lock ever invented. Five thousand of them have been ordered by the Post Office Department.

WOOD-SAWING MACHINE. — A recent Western invention for sawing wood consists of two saws so placed that two cuts can be made at once. The wood is fed to these as grain is fed in a threshing machine, and after being sawed is carried away by an elevator, like the threshed straw. The machinery is propelled by an eight-horse-power engine. The whole apparatus, engine, boiler, saws and elevator, is built upon a platform, and enclosed like a box-car, in convenient compass to be loaded upon a flat-car, and shipped from station to station. With a little change, trucks can be placed underneath like a pile-driving car, and then it can be moved upon the track as a separate car. In ten hours it can prepare from 90 to 100 cords easily. It requires nine men to work it, feed and take care of the wood.

SILK MANUFACTURE IN CANADA. — The *Ottawa Journal* gives some interesting facts concerning the French colony that is now trying the experiment of silk culture in Canada. A building twenty-five by eighty feet is now going up for a factory, and it is expected that a larger one will soon be added. Seed for twenty thousand mulberry trees was planted last spring. M. De Boussière, one of the managers of the enterprise, says that the young trees have grown much more rapidly here than in France. Some of them are now thirty inches high, having grown as much in six months as they do in France in nine months. The velvet trimming manufactures heretofore have been of different widths up to half an inch, but new looms, which will manufacture much wider goods to conform to the present fashions, are on the way from New York, and will be put up at once. Another loom, to weave silk dress goods, is to be put up at an early day. One great advantage of this trimming above most of the ordinary goods is that it has a selvage on both edges, an advantage readily appreciated by the ladies.

A FLOOR-WASHING MACHINE. — A canny Scotchman has invented a machine for washing floors. It consists of a frame on wheels to be moved over the surface to be cleansed. This frame carries two tanks or cisterns, one of which holds the cleansing water or other liquid, while the other receives the liquid after it is made dirty in the operation. On the lower part of the machine a revolving brush is carried, and in front of it is a rose or perforated pipe, by means of which the washing liquid from the tank or cistern is discharged upon the floor. The brush is geared by bevel or mitre wheels to the shaft of two other brushes, all the brushes being brought in contact with the surface to be washed.

BLEACHING FEATHERS.— The *Moniteur de la Teinture* gives an entirely new process by which even black ostrich and eagle feathers can be easily bleached, and thus rendered much more valuable. These feathers are immersed for three or four hours in a lukewarm solution of bichromate of potash, to which a few drops of nitric acid have been added. At the expiration of this time the feathers will have assumed a green color, due to the deposition upon them of finely divided oxide of chromium. This oxide is removed by means of sulphurous acid, and the feathers after this treatment are perfectly white. The precautions to be observed are, not to take too concentrated a solution of bichromate of potash, and to avoid an excess of nitric acid.

SIZE FOR DRESSING COTTON. — An improved size for dressing cotton yarn or cotton warps is stated to consist of 280 pounds of flour, one pound of tallow, and one half to two per cent. of the amount of flour employed, of paraffine. The paraffine may be made to replace the whole or a part of the tallow usually employed.

TO UNITE WATER-PIPES. — An excellent material for uniting water-pipes is prepared by combining four parts of good Portland cement and one part of unslaked lime, mixed together in small portions in a stout mortar, adding enough water to permit it to be reduced to a soft paste. Pipes thus united have been in use more than six years without any leak.

A GALVANIC CELL WITH ONE LIQUID. — A French chemical journal describes such a cell, composed of zinc and carbon placed in a fluid made up of 40 parts of water, 4.5 parts of bichromate of potassa, 9 parts of concentrated sulphuric acid, 4 parts of sulphate of soda, and 4 parts of the double sulphate of potassa and iron. This produces a very regular current. The zinc need not be amalgamated, and no gas is evolved.

PRACTICAL RECIPES.

A CEMENT TO STOP FLAWS OR CRACKS IN WOOD OF ANY KIND. — Put any quantity of fine sawdust of the same kind of wood into an earthen pan, and pour boiling water on it; stir it well, and let it remain for a week or ten days, occasionally stirring it; then boil it for some time, and it will be of the consistence of pulp or paste; put it into a coarse cloth, and squeeze all the moisture from it. Keep for use, and, when wanted, mix a sufficient quantity of thin glue to make it into a paste; rub it well into the cracks, or fill up the holes in your work with it. When quite hard and dry, clean the work off, and, if carefully done, you will scarcely discern the imperfection.

WHITE POLISH FOR LIGHT WOODS. — White (bleached) shellac, 3 oz.; white gum benzoin, 1 oz.; gum sandarac, 1-2 oz.; spirits of wine, or naphtha, 1 pint; dissolve.

TO CLEAN AND RESTORE THE ELASTICITY OF CANE CHAIR BOTTOMS, COUCHES, ETC. — Turn up the chair bottom, and with hot water and a sponge wash the cane-work, so that it may be thoroughly soaked. Should it be dirty, use a little soap. Let it dry in the air, and it will be as tight and firm as when new, provided the cane be not broken.

TO CLEAN MARBLE OR SCAGLIOLA. — Mix the strongest soap-lees with quicklime, to the consistency of milk; let it lie on the stone for twenty-four hours; then clean it off, and wash with soap and water, and it will appear as new.

This may be improved by rubbing or polishing it afterwards with fine putty-powder and olive-oil.

CEMENT FOR LEATHER BELTING. — Take of common glue and American isinglass, equal parts; place them in a boiler, and add water sufficient to just cover the whole. Let it soak ten hours, then bring the whole to a boiling heat, and add pure tannin until the whole becomes ropy or appears like the white of eggs. Apply it warm. Buff the grain off the leather where it is to be cemented; rub the joint surfaces solidly together, let it dry a few hours, and it is ready for practical use; and if properly put together, it will not need riveting, as the cement is nearly of the same nature as the leather itself.

PAPER LABELS FOR GLASS BOTTLES. — These will last as long as glass if they are covered with egg albumen, and then exposed to the action of steam until the albumen coagulates. If they are now dried in a temperature of 212° F., the albumen will become hard and clear, and oils or acids will not affect them.

TO BLEACH SPONGES. — The *Druggists' Circular* gives the following in reply to an inquiry for a method of bleaching sponges without weakening their texture: —

"White sponge is prepared commonly by soaking the common sponge in very *dilute hydrochloric acid* to remove the calcareous matter, then in cold water, changing it frequently, and squeezing the sponge out each time; it is then soaked in water holding a *little sulphurous acid*, or a very little *chlorine* in solution. Lastly, the sponge is washed in clean water and scented with rose or other fragrant water, and dried. Another way is to soak it in *dilute hydrochloric acid* for ten hours, then wash well with water and immerse in a solution of *hyposulphite of soda*, with a small addition of diluted hydrochloric acid, wash and dry. Be careful to use the acids not too strong."

If the sponge be afterwards dipped in glycerine, and well pressed, to remove excess of liquid, it remains elastic, and can be used for mattresses, cushions, and general upholstery. Sponge mattresses prepared in this way are now finding great favor. It is, of course, not necessary to bleach the sponge where it is intended to be used for such purposes.

VARNISH FOR CARVED WORK. — The following is highly commended as a "polish varnish:" One ounce white resin and one ounce seedlac, dissolved in half a pint of alcohol. Lay on with a brush, warm; and warm the work, if possible; at any rate, have it thoroughly dry.

Electric Signals for Brakemen. — The experiment of using the galvanic current for train signals is being tried on the Boston and Worcester railway. An electro-magnetic telegraph, worked by a small battery, extends from the cab of the locomotive, through the whole length of the train. There is an alarm-bell in the cab and upon each car. Two wires pass between the cars, covered with tarred twine. One end of this "cable" is securely fastened to the car, while at the other end is a copper link, which is placed on a spring-hammer on the other car. This link, when in its proper position, keeps the connection open. It is so arranged that, should a part of the train become detached, the link is pulled off, the circuit is broken, and the bell in the locomotive and on each car is kept ringing until the circuit is again closed. Besides automatically indicating the breaking of a train, the apparatus is useful in signaling between the engineer and his brakemen. Instead of blowing the whistle to notify them to apply or let off the brakes, the engineer simply touches a little knob that rings the bell on each car almost instantly. By this method the brakeman on the rear car is notified as surely as though on the first car, which is not the case by the present arrangement, for it frequently happens that the sound of the whistle does not reach the end of a long train. If there is trouble in any car, the conductor or brakeman touches a little knob, the signal is given, the engineer and the other brakemen are warned, and the train is stopped.

The War Balloons. — Hereafter no city can be so shut in by siege that messengers cannot be sent out with an approximation to safety. No incidents of the contest have been more picturesque than the assembling of the population of the capital to witness the starting of the aerial envoys; the passing in a few seconds of time from the heart of the French city to the encircling lines of the Prussians; the gauntlet of musket-balls and shells and rockets; the audacious scattering from a safe height of printed appeals inciting to mutiny in the German ranks; the double peril of landing, in which an unlucky wee may be more fatal than the shot of an enemy, or an exultant enemy may be hiding behind the nearest tree; the ovation awarded to the successful voyagers by a friendly people, the distribution of letters and messages, the sending back of carrier pigeons to bear to the besieged the news from without. . . . But there are possible developments of air-ships which would imply a revolution in warfare; and an English journal speaks half seriously and half jocosely when it inquires the value of the wooden walls, the iron turrets, the gallant tars and harbor-forts of a maritime nation, in case of a descent of some scores of thousands of Uhlans and Zouaves, each squad coming fully armed and provisioned in its own balloon. — *Boston Advertiser.*

Agriculture.

RECLAIMING WET MEADOWS.

In the Address upon "Manures General and Special," by the Editor of the Journal, the following statements are presented regarding some experiments upon bog lands at Lakeside Farm: —

Upon my reclaimed meadows no farm dung has been used excepting on a small patch for the purpose of experiment, and I have secured large crops of red-top and timothy during the past five years. The method of treatment has been varied with the view of ascertaining the best way of bringing them into condition to produce upland grasses. I have dressed certain parcels with the farm-made superphosphate, with a mixture of bone and ashes, with guano, fish pomace, combinations of salt and lime, and with sulphate of ammonia and nitrate of soda. It must be remembered that my low lands are pure peat bogs, of such a nature that, if the water was withdrawn, and the deposits allowed to become dry, fire would consume the whole to ashes. The elevation of the bog above the level of Lake Kenoza, on which it borders, is only nine inches in the winter and spring when the lake is at its highest altitude; consequently, it is an unpromising and difficult field upon which to experiment with the view of driving out the worthless meadow grasses. Indeed, no one in whose judgment I placed confidence would afford me any encouragement to expect success. It was regarded as impossible to renovate meadows which for so large a part of the year were almost submerged, and which could not be drained. Nevertheless the experiment has proved successful, and crops already secured have paid all the expenses of renovation and treatment. Upon two acres of the six which are now producing upland grasses, a coating of sand three inches in thickness was placed, after thorough spading and pulverizing the bog; upon this a dressing made of equal parts of fine bone and ashes, two thousand pounds in quantity, was evenly distributed, and it was then seeded down with red-top and timothy, covered in with a brush harrow. The work was done in the months of August and September, 1866. The first crop of hay in 1867 was a little above one and a half tons to the acre, the succeeding crop was two and a half tons, and those which have since been taken from the field have averaged about the same amount. The present autumn a light top dressing of farmyard dung has been given the field with the view of observing its effects. Meadow grasses have not yet made their appearance to any extent. After removing the crop next season, a new seeding will be given the field, and the experiment continued. One acre of the remaining six received no coating of sand, but after digging out the hassocks and burning them, the patch was turned over with the spade, fertilized with three hundred pounds of bone dust, and two hundred of guano, and seeded down similar to the other. This was accomplished in the autumn of 1868. In 1869 the first crop and aftermath gave three tons to the acre. The present season the two crops have exceeded that amount. Another acre bordering directly upon the lake, but slightly more elevated, was reclaimed in the same manner in 1867, and treated with one ton of dry fish pomace. It gave a crop the succeeding year of one and a half tons to the acre, and since the yield has been about two tons each season. In 1869, two more acres were put in condition, fertilizing one half with pure bone and spent ashes, the other with farm superphosphate. The crop this season upon both sections has been nearly alike, slightly exceeding one and a half tons to the acre. The remainder has been seeded down the present autumn, using upon one portion farm dung, upon another lime, upon two other portions various combinations of salts, which it is needless to mention, as no results have yet been reached. Some of these experiments have been continued long enough to learn something of the value of the methods of treatment, while the others have not. Several plats of the meadow have been put in condition and left one season without any fertilizing agent, and the result has been that ferns and coarse meadow plants have flourished together in rank luxuriance, thus proving the needed presence and high utility of the plant stimulants employed.

I think from the brief and imperfect statements presented, it will be conceded that wet peat meadows can be profitably reclaimed, and fertilized by special or concentrated agents easy and convenient to handle. I shall not venture upon the expression of opinions at present regarding the most effective and cheapest agents, as these points are not satisfactorily settled. After a few more seasons have passed, we shall have results which will enable us to form a more exact and reliable judgment in regard to the matter. The great value of our low lands in Massachusetts is as yet imperfectly understood, although attention has been called to them persistently through books and the agricultural press. Farmers, as a general rule, fear to have anything to do with the soft peat-bogs so common throughout the State. Their experience in miring oxen and horses in attempting to plough or haul manure, is not favorable to a prosecution of the work of renovation. When it is known that the spade will do the work of the plough, and that fertilizers of great efficacy can be carried in a basket upon the shoulder, a little more courage may possibly be infused into the owners of such lands, and they may seek to draw from them their hidden wealth by the work of reclamation. It must, however, be distinctly understood that all meadows are not of a character to pay for any labor that may be bestowed upon them. It is important that every farmer should carefully examine his low grounds before commencing improvements, that he may not subject himself to disappointment and loss. It is certainly difficult clearly to describe a meadow that will not after working bear good crops of sweet grasses, but I am confident I could point out such if allowed five minutes' work upon it with a spade. A piece of low land deficient in peat, with a superficial, clayey covering, overrun with moss or short matted grass, will not pay for the labor of renovation; neither will a meadow pay which is surrounded with a forest which places it in the shade half the hours of the day, no matter what may be the nature of the deposit. A meadow permanently wet, and which cannot be drained, is one upon which labor is usually wholly lost. Any low land open to the air and sunlight, and which is raised one foot above the highest water-level in the spring, can generally be converted into a profitable field, yielding abundance of the nutritious grasses. More attention should be bestowed upon such lands, as the hay crop is one of the most important and profitable produced upon our farms.

SOUND ADVICE TO SOUTHERN FARMERS.

From an admirable Address by General Capron, Commissioner of Agriculture, before the Agricultural Congress at Augusta, Ga., we make the following extract, which, though of special interest to Southern agriculturists, has no sectional limitation in the *principles* inculcated: —

"My first counsel would be — practice a restorative instead of an exhaustive system of agriculture. A system that involves abandonment of lands and removal to new scenes is unworthy of the age, and a reproach to modern civilization.

"No man is worthy to be a farmer who does not annually leave his land in better tilth and strength than he found it. The intellect must share more largely with muscle the toil of agriculture; machinery directed by skilled labor, and propelled by brute force, and also by the mighty power of steam, must take the place of expensive and insufficient human strength. This change, as I said in this State a year ago, 'involves the necessity for smaller farms, better culture, liberal use of manure, rotation in crops, and a larger working capital in proportion to permanent investment.' You are already spending millions annually on the old lands of the Atlantic States for commercial fertilizers. While I would commend a judicious expenditure in this direction, I would make this a basis of a practical rotation with a course of grasses and other restorative agencies of scientific agriculture.

"The business of agriculture should be an industry and not a speculation. The insane pursuit of specialties has long been a curse to American agri-

culture. A whole community runs wild upon hops, when selling at fifty cents per pound, and in two years they are scarcely worth the price of picking, and extravagance begotten of high expectations is forthwith followed by bankruptcy. Wheat brings $2 per bushel, and whole States become wheat fields, while every othe interest languishes, until the bread crop becomes so abundant as to be fed to swine in preference to shipment for human food. The sheep, with wool at $1 per pound, holds high place in popular esteem, but is kicked from the pasture by every Randolph of the farm at the first indication of a heavy decline in the value of its fleece. In your section cotton, a great boon to your agriculture as a constituent in your aggregate of production, may become an unmitigated evil if left to usurp the place of all other crops. The crop of last year produced $100,000 000, more than 150 per cent. larger than ten years ago. Three millions of bales may command a profit of $40 per bale, while five millions may not bring a dollar above their cost. But present profit is not the main consideration. The increase in value and enlargement of the productive capacity of the soil, by a judicious rotation, including the restorative influences of green cropping and cattle feed ng, is an increase of capital, a source of larger annual income, and an addition to the inheritance of one's children. It not only insures a profit from cotton culture, but enables the planter to pocket the entire proceeds of its sale, other products feeding man and beast."

WHAT DOMESTIC ECONOMY MEANS.

FROM an article with this heading in *The Farmer and Artisan*, one of our esteemed Southern exchanges, we make the following extracts : —

It means the careful saving of *every item* of any value, no matter how small, and the putting of every item to some *good* use; or it means the careful husbanding of these little odds and ends that occur in every family, but which many families throw away, and the application of these little items to *service* in the economy of the household. It has reference to *every article*, of whatever kind, that passes through the hands of the family. It means that the farmer knows just how much to feed his stock, also where and how to feed it that nothing be lost; that he knows how to save feed by providing comfortable shelters for his stock, and how to save his buildings by keeping them in good repair; and that he knows how to save money by turning everything around him, that has any of the elements of plant food, into manures. . . .

Domestic economy means that all old iron, old tin-ware, nails, shoes, worn-out tools, bits of wire, broken glass, empty bottles and vials, cast-off garments, bits of cloth and thread, scrap paper, etc., are put away in appropriate places, each by itself, for any service that occasion may require. It means that ashes, sweepings of the yard, old mortar, pounded brick-bats, bones, hair, feathers, urine from the chamber, the accumulation of privies, weeds, soap-suds, even the washings of the hands and face, dead animals, old salt, and everything of like character are composted under shelter to be applied to future crops.

It means that the excrements of every animal upon the farm are protected under cover until wanted for use in the fields; that carts and wagons are frequently oiled; that farm tools are painted annually, and kept under cover when not in use. It means that insectivorous birds are encouraged upon the premises; but that dogs and cats are rightly banished. It means that the best breeds of stock and the best implements of husbandry are used. It means that the health of the family, and of the stock, are looked after by providing plenty of good water, and a free circulation of pure air in the dwellings of both man and beast. . . .

Domestic economy is a *science* — the science of *saving*. It is comprehended in one brief sentence, uttered by the wisest Being that ever walked on earth: "Gather up the *fragments* that remain, that *nothing be lost!*"

POISONOUS FERTILIZERS.

A CORRESPONDENT calls attention in a scientific journal to a source of ill-health that we do not remember to have seen noticed before. Speaking of preparing animal manures by sulphuric acid, he says: —

Common oil of vitriol is, as far as I know, the substance used by all manufacturers; but I think none but the chemically pure acid should be used. The common acid often contains a small quantity of lead and arsenic, both of which are known to be absorbed by plants when presented to their roots.

Dr. Edmund Davy, professor of agriculture and agricultural chemistry in the Royal Dublin Society, published a paper, in 1859, calling attention to the danger of using manures containing arsenic; yet there has not, up to the present time, I believe, been a pure article of superphosphate of lime put in the market. I think the use, for the purpose mentioned, of acid containing arsenic or lead ought to be prohibited by law.

Remarks. — The above absurd item has been "going the rounds" of the press during the past six months, and it is quite time that it was stopped. This attempt to frighten farmers who are enterprising enough to dissolve bones and prepare their own fertilizers is hurtful to the interests of agriculture and derogatory to science. In the ordinary sulphuric acid of commerce, which is made from Sicilian sulphur and condensed in platinum retorts, the amount of sulphate of lead present is but a mere trace, seldom exceeding one fourth of one per cent. The same may be said of arsenic; some specimens of acid from the best makers do not afford even a trace of this metal or any of its salts. The dunce who started this item, probably read in some old book or journal, that specimens of acid, prepared in England some years ago from iron pyrites, were found by Dr. Rees, Mr. Watson, and others, to contain arsenic, and hence seized hold of the idea of making a sensational article on "poisonous fertilizers." Such loose statements are fraught with evil, and cannot be too severely condemned. It may be said that the quantities of lead and arsenic found in the worst specimens of commercial acid would not have the slightest influence upon crops, when presented through the medium of superphosphates. Farmers and horticulturists need have no fear of deleterious effects from the use of any of the acids found in the market.

TEA CULTURE IN THE UNITED STATES.

EXPERIMENTS recently made in Tennessee, South Carolina, and California, have demonstrated that the climate of many parts of the United States is well adapted to the cultivation of the Chinese tea plant. In China it is grown between the twentieth and fortieth degrees of north latitude. It does not require a warm climate, is very hardy, and is said to thrive better when subject to freezing in the winter than when not thus exposed. While it grows wild in some sections of China on the hill-sides, it flourishes best with careful culture on the plains, where the soil is well drained and not too rich. One crop of leaves usually is gathered in the spring and another in the fall, the former being considered the best. The plants are set in hills, very much as plant corn, three or four feet apart; the growth about three feet in height, and an ordinary plan productive for about ten years, at the expiration which time it requires to be renewed. No e worth gathering is produced until the plant is th years old.

The proper time for planting is in November a December; and the plants are very prolific. T picking season begins about the first of April a continues until October, at intervals of from fift to twenty days. The yield of a well cultivated pl tation is about one pound of prepared tea to plant, or four pounds of leaves in their green sta An acre of land will sustain about twelve hund plants, and consequently yields that number pounds of tea when in full bearing. The Chin method of preparing and manufacturing tea is v primitive, and can doubtless be improved by the of machinery, especially in the rolling process.

Dr. Smith, of Greenville, South Carolina, has c tivated tea in the mountainous districts of the Sta exposed to the frosts and ice of winter without jury. It is his opinion that there is no climatic stacle to its successful cultivation in the Unit States. If the experiments now making prove su cessful and remunerative, there will hardly be limit to the extent which the culture may assu on the Pacific coast, as well as in the hilly regio of some of our Southern States.

AGRICULTURAL NOTES.

EGGS AND ORANGES IN CALIFORNIA. — T California papers could easily furnish material f a "Library of Wonders" much more extended th the one which Scribner and Company are publis ing. The *Scientific Press*, of San Francisco, whi is thoroughly trustworthy even when it tells "tal stories, reports eggs 8 1-4 by 6 1-8 inches in circu ference, and says that such achievements are co mon with the hens out there. The same pap gives a picture of a "bouquet" of Californ oranges, of which the following is a descriptio "This branch is about two feet long, and som thing less than an inch in diameter, where it w taken from the tree. It contained, when tak off, 75 oranges, five having dropped off after th were matured, but before the branch was remov from the tree. Thirty-seven, only, are seen in t engraving, the balance being concealed by the fo age, or fruit in front. When looking up direct underneath the branch, the eye rests upon a perfe mass of fruit, much as it would appear if pack in a basket. We doubt if a more prolific grow could be produced in any part of the world.

"The tree from which the branch was taken about 13 years old, and bore in all about 2,0 oranges."

A NEW USE FOR VINE PRUNINGS. — The ne wood prunings of the vine have lately been utilize for making wine and vinegar. After being cut smal they are bruised and put into a vat or mashing tu and boiling water poured on them, in the same wa as is done with malt. One experimenter says th they produce liquor of a fine vinous quality, whic on being fermented, makes a very fine beverag either mild or strong, as you please, and on bein distilled, produces an excellent spirit of the natur of brandy. In the course of his experiments h found that the fermented liquor from the pruning particularly the tendrils, when allowed to pass int the acetous fermentation, makes uncommonly fin vinegar.

A WESTERN BEAN. — We wonder if the famou beanstalk cultivated by Jack in the nursery tale wa a castor bean. This seems not improbable, when we learn that the editor of *Howe's Monthly*, at Saint Louis, has raised the past season a castor bean plant which was 12½ inches in circumference at the

round, and 15 feet 3 inches high, and the aggregate ength of the branches was 90 feet 8 inches; so that he whole longitudinal growth of the main stem and ranches was 105 feet 10 inches. The branches vere evenly distributed along the length of the stem, iving the tree (for such it may be called) a very ymmetrical form.

REAPING AND MOWING MACHINES. — The nanufacture of these machines has increased to normous proportions in this country. The annual roduction is now estimated at about 125,000 machines. Few facts more clearly demonstrate the nmense wealth of the farmers of our country than hat they expend each year about $20,000,000 in he purchase of this one class of implements.

SLOW CHURNING PREFERABLE. — The *Scottish Farmer* is unwilling to concede any merit to the ewly invented churns that claim to produce butter o quickly, and argues strongly in favor of the atient, careful mode of churning. It says: —

And here we would state that we do not believe quick or rather rapid churning. We have, of te, been accustomed to the advertisements of hurns, the great merit of which is stated to be that ey produce the butter in a very short time. This uickness is very delusive; it conveys the idea that mething is gained; but the point is not, is time ined? but is the butter in the condition in which should be? To do work quickly is not always to it well; on the contrary, we are inclined to say at, as a rule, good work almost always includes e outlay of patient labor. But this notion of ick churning as the right thing to aim at proceeds om an ignorance of what the points involved in tter-making really are. Quickly made butter may good enough if it is to be used at once, but it ill not keep well. The reason is simply this — at all the buttery particles of the cream or milk e encased with thin pellicles of caseine or the eesy particles of the milk; if these are allowed be in too great a proportion, the butter has that eesy flavor we all so much dislike, and this will the case if the churning is done so quickly as fail to break up or separate the caseine pellicles m the oily or buttery particles; this perfect sepation can only be effected by slow churning. Of urse there is a medium; but we should be inned to place the minimum time in which the urning operation is to be kept up at thirty mins; between this and forty-five or sixty minutes, he butter "comes," then the quality, other things ng equal, will be good.

THE "FAT CONTRIBUTOR" ON FARMING. — correspondent asks us what we think of late ughing. Ploughing should not be continued later n ten or eleven o'clock at night. It gets the ses in the habit of staying out late, and unduly oses the plough. We have known ploughs to acre spring-halt and inflammatory rheumatism from ploughing. Don't do it.

To another correspondent, who wants us to sugt a good drain on a farm, we would say a heavy rtgage at ten per cent. will drain it about as idly as anything we know of.

When you make cider, select nothing but the ndest turnips, chopping them into sled length ore cradling them. In boiling your cider use nty of ice, and when boiled hang it up in the to dry.

A pick-axe should never be used in picking apples. has a tendency to break down the vines and dam the hive.

n cutting down hemlock trees for canning, select largest. Don't throw away the chips, as they ke fine parlor ornaments, encased in rustic frames salt and vinegar.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, APRIL 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

TO ADVERTISERS.

Advertisers are hereby informed that the Boston Journal of Chemistry circulates more copies monthly than any other periodical of its class in this country. It goes into every State and Territory of the United States, and to the British Provinces, England, Scotland, Germany, Australia, etc. It is the best medium for advertising drugs, medicines, chemical substances, chemical and philosophical apparatus, telescopes, microscopes, educational institutions, lectures, books, musical instruments, articles of food, furniture, agricultural implements, seeds, fertilizers, wines, soda-water apparatus, surgical instruments, the business of physicians and druggists, etc., etc., that the country affords.

THE SPREAD OF "DARWINISM."

DARWIN'S "Origin of Species by Means of Natural Selection" was first published in 1859. Its doctrines at first met with little favor from scientific men. On the contrary, they were generally denounced as false and absurd. But they soon began to be accepted here and there, especially among the rising generation of naturalists; and at the present time, it is safe to say that those who oppose them are decidedly in the minority. There is no more striking fact in the history of theoretical science than the progress which this radical and revolutionary system has made in the brief period of ten years. "The views of Mr. Darwin," as a recent writer has said, "will undoubtedly undergo both modification and extension in the future; but in their broad scope they are not only extensively assented to, but they are guiding the researches of the foremost scientific minds of the world."

Among the recent conquests made by Darwinism, in England, is Sir Charles Lyell, who has been called "the most learned of living geologists." After fifty years of study upon the history of life as illustrated by "the great stone book of nature," and after teaching the older theories in his many works on the subject, he has at length given up those views as untenable, and become a convert to the Darwinian doctrines.

In Germany the new system has been more widely adopted than in England. Prof. Geikie, the eminent British geologist, after attending the recent Scientific Congress at Innsbrück, at which some eight hundred German *savants* were present, makes the following report: —

"What specially struck me was the universal sway which the writings of Darwin now exercise over the German mind. You see it on every side, in private conversation, in printed papers, in all the many sections into which such a meeting as that at Innsbrück divides. Darwin's name is often mentioned, and always with the profoundest veneration. But even where no allusion is specially made to him, nay, even more markedly, where such allusion is absent, we see how thoroughly his doctrines have permeated the scientific mind, even in those departments of knowledge which might seem at first sight to be farthest from natural history. 'You are still discussing in England,' said a German friend to me, 'whether or not the theory of Darwin can be true. We have got a long way beyond that here. His theory is now our common starting-point.' And, so far as my experience went, I found it to be so."

In this country, the acceptance of Darwin's views has not been so general, but it is evident that they are spreading among scientific men. At the last meeting of the American Association, at Troy, Prof. Meehan read a paper on one branch of Darwin's researches, in which he had at first supposed him in error, but at last found him to be right. In the subsequent discussion, Dr. Gray, the distinguished botanist, declared that "he had frequently attempted to catch Darwin tripping in this particular, and had referred to him many instances which he himself at the time considered opposed to the theory; but in every case he had been forced to withdraw his objection."

This is like the testimony of Müller, the famous German naturalist, who tested Darwin's doctrines critically in their application to the development of the crustacea. "I took no small pains," he says, "to detect any contradictions among the inferences as to the class of crustacea furnished by the Darwinian theory. But I found none either then or subsequently. Those which I thought I had found were dispelled on closer consideration, or eventually became converted into supports for Darwin's theory."

In the "Origin of Species" Darwin did not discuss the bearing of his theories upon the origin of the human race; for, as he has since said, "I thought that I should thus only add to the prejudices against my views." But in his recent book, "The Descent of Man" (reprinted here by the Appletons), he boldly takes the ground that man, like other organic beings, must have descended from preëxisting forms of lower rank. He says: —

"The early progenitors of man were no doubt once covered with hair, both sexes having beards; their ears were pointed and capable of movement; and their bodies were provided with a tail, having the proper muscles. Their limbs and bodies were also acted on by many muscles which now only occasionally reappear, but are normally present in the Quadrumana."

After remarking that "the most ancient progenitors" of vertebrate animals appear to have been "a group of marine animals, resembling the larvæ of existing Ascidians," and tracing the lineage down — or up — through lower orders and higher orders of fishes, reptiles, and birds (for "birds and reptiles were once intimately connected together"), until we come to mammals, he says: —

"In the class of mammals the steps are not difficult to conceive which led from the ancient Monotremata to the ancient Marsupials, and from these to the early progenitors of the placental mammals. We may thus ascend to the Lemuridæ; and the interval is not wide from these to the Simiadæ. The Simiadæ then branched off into two great stems, the New World and Old World monkeys; and from the latter, at a remote period, man, the wonder and glory of the universe, proceeded. . . .

"It is only our natural prejudice, and that arrogance which made our forefathers declare that they

were descended from demigods, which lead us to demur to this conclusion. But the time will before long come when it will be thought wonderful that naturalists, who were well acquainted with the comparative structure and development of man and other mammals, should have believed that each was the work of a separate act of creation."

For ourselves — not from "natural prejudice" or "arrogance," but simply because we cannot as yet accept our author's reasoning as conclusive — we are not satisfied with this genealogy; but it is too late to laugh at it as absurd and ridiculous. Neither is it necessarily inconsistent with the generally accepted theories concerning the creation. We do not deny the agency of the Divine Mind in the creation of the individuals of a species because they are developed from "pre-existing forms" by ordinary reproduction; and the Darwinian theory merely extends the range of this mode of development. It teaches, that species are developed from earlier and simpler forms, which have been gradually modified by the surrounding conditions of climate, etc., those modifications being perpetuated which suit the varied conditions. In other words, it teaches, as we said last November, that nature — or God, for we recognize God *in* nature — does just what man does when he produces new varieties. This is by no means ignoring creative action, but merely taking a new view of the way in which that action has been exerted. It is assuming that the creative power is everywhere present, acting now and forever, instead of acting once for all, as the more familiar theory of the creation supposes.

ENGLISH ADVERTISING.

If we are unwilling to believe that English inventors and manufacturers are more ingenious than we are in devising new machines or art processes, we must admit that they are far ahead of us in ingenious ways and methods of advertising their wares. At the last meeting of the British Association for the Advancement of Science, a Mr. A. McGordon succeeded in introducing and reading, in one of the sections, a paper on "How to Prevent Lead Poisoning in Water," in which unqualified commendation was bestowed upon the "tin-lined lead pipe," the manufacture of which had but recently been commenced in England, and which needed some novel mode of advertising to bring it into notice. Whether the "cat in the meal" was discovered by those who listened, we are not informed. Indeed, so far as Mr. McGordon was concerned, this was a matter of no account; for the moment he had read his "paper," his object was accomplished, and his gratuitous advertising secured. He could hardly escape criticism and rebuke, however, if any one remained to listen; for the "paper" is full of errors and absurdities, and affords evidence of being the work of a designing man and ignoramus in science. In order to bring into greater prominence the new "tin-lined lead pipe," he starts off with a sweeping condemnation of leaden pipes and vessels, and declares that everything is "poisoned and polluted which comes in contact with the metal." Galvanized iron water-pipes are dismissed with the wise remark that they are objectionable because they have "diminished tenacity, and are liable to splitting and corrosion." What is meant by "diminished tenacity," and by "splitting," we do not clearly understand. In this country we are not afraid of their "tenacity" or "splitting" weaknesses. It would indeed be better for the community if every foot of the pipe "split open" the moment it was put in position. The "corrosion" is what particularly troubles us, in the galvanized pipes. This paper has been published in the *Medical Times and Gazette*, of London, and that journal does not point out a single absurd statement, or express dissent from any one conclusion. It has also been republished in some medical journals here without comment, and so Mr. McGordon is passing his advertisement smoothly along without any detriment to his pocket. As regards the "tin-lined lead pipe," we have in the Journal expressed disapproval of its form of construction, and given reasons why we regard it as unscientific and unsafe. We have thus far seen no reason to change the opinions presented.

GALVANIZED WATER-PIPES.

The Board of Melrose Water Commissioners have taken prompt and active measures to prevent the use of the galvanized pipes by water takers. The following Circular has been printed and widely distributed: —

To Spot Pond Water Takers in Melrose.

Melrose, *March* 1, 1871.

After the expiration of our contract with Mr. Norman for laying lined service-pipes, Messrs. Ellis & Co. laid nine galvanized iron service-pipes. From investigation and facts which have come to our knowledge, we felt it to be our duty to take action, and at a meeting of the Board held last Saturday evening, a vote was passed authorizing the taking up of the galvanized iron as soon as possible, and substituting the lined pipe. In the mean time we recommend drawing liberally before using the water, so as to take as little poison into the system as possible.

We regret so many of our citizens have attached galvanized iron to their service pipe, thereby endangering the health of so many. We beg of you to remove such pipe at once, and substitute either iron lined with cement, or lead, which, according to analysis below, may be considered comparatively safe. We are in earnest in this matter, and are fully satisfied that any one drinking water through a galvanized iron pipe is taking more or less poison into the system.

Wingate P. Sargent,
Chairman of Melrose Water Commissioners.

Boston, *January* 14, 1871.

To Melrose Water Commissioners:

The specimen of water taken from Spot Pond in Melrose, Mass., has been received, and we have conducted a series of experiments with the view of ascertaining its action upon zinc-covered iron pipes (galvanized pipes), and upon pipes constructed of lead. We find its action upon galvanized iron pipe to be so energetic and immediate that, upon allowing a current of the water to flow slowly through a section of the pipe, the protoxide of zinc was formed in considerable quantities, and was detected in the water which passed through. A section of the pipe was filled with the water, and allowed to remain one hour. Upon examining the water, a still larger amount of the protoxide of zinc, and also a small quantity of the carbonate of the protoxide, was found to be held in it. The water allowed to remain twenty-four hours in a section of the pipe gave a mixture of the protoxide and carbonate of zinc amounting in quantity to six grains to the gallon. Experiments made upon a section of the pipe, changing the water every twelve hours, with the view of ascertaining if the action upon it was continuous, showed that the zinc salts were constantly present in the water, and that the action was unintermittin The water of Spot Pond acts directly upon the zi covering, forming a protoxide of the metal, and li erating hydrogen from water decomposition. part of the protoxide is changed into a carbonate protoxide, and a minute portion into other salts fro the action of organic acids held in the water.

The solution of the protoxide of zinc in the wat is facilitated by the presence of alkalies and alkali earths, and hence there is increased danger fro attaching galvanized pipes to mains constructed hydraulic cement, as there is communicated to th water an alkaline quality resulting from contact wi the cement. It is proved by our investigations th the use of galvanized iron service-pipes in conduc ing Spot Pond water, is highly dangerous to healt and should under no circumstances be permitte The action of the water upon leaden pipes corr sponds with that taken from Cochituate Lake, an from Round Pond in Haverhill, Mass. Leade pipes immersed in the water undergo slow oxidatio and the water affords a decided lead reaction whe tested during the first forty-eight hours. This rea tion is afforded in water changed as often as once two hours. By the change of the partially solubl oxide into insoluble carbonate, a coating is forme upon the pipe which arrests farther decompositio and the water in contact remains uncontaminate It is apparent that of the two varieties of service-pipe those constructed of lead are far less dangerous, under ordinary conditions the action of the water protective in the way described.

J. R. Nichols & Co., *Chemists.*

FRAUDULENT KEROSENE.

The readers of the Journal will rememb that about one year ago we gave an accou of a lamp explosion in this city, by which Mr Hiram Wellington, a lawyer, was seriously in jured. The fraudulent liquid was purchased o a retail dealer on Cambridge Street, who allege that he bought it of the Downer Kerosene O Co. Mr. Wellington, wishing to secure respon sible parties for defendants, and believing th the Downer Company were liable for the dam age, brought them into the Superior Court to an swer a suit. Judge Lord ruled that Wellingto had no cause for action against Downer, and th case was carried on appeal to the Supreme Cour A decision has recently been reached in the cas and Judge Lord has been overruled, and the cas remanded back to the Superior Court for tria This is an important decision, as it has a direc bearing upon the sale of naphthas by manufactur ers to dealers for illuminating purposes. Th following is a report of the decision, copied fro the *Advertiser* of this city: —

Hiram Wellington vs. The Downer Kerosene O Company. — The plaintiff in this case alleged tha the defendants are manufacturers and dealers in oi They sold to Nathaniel E. Chase, who was know to them to be a retailer of oils to be burned i lamps, a barrel of naphtha for the purpose of bein resold, they knowing the purpose of Chase to retai it. Chase, not knowing its dangerous character, re sold a pint of it to the plaintiff to be burned in lamp. While the plaintiff, not knowing that it wa dangerous, was using it for illuminating purposes, i ignited and exploded, whereby the plaintiff wa badly burned. There was a second count founde upon the statute of 1867, chapter 286. The plain tiff at the trial in the Superior Court having offere evidence tending to prove these allegations, th judge ruled that, if proved, they would not sustain the action, and directed a verdict for the defendants.

Exceptions taken to this ruling have now been

stained by the Supreme Court upon the ground that "upon the facts offered to be proved at the trial, the plaintiff, if in no fault himself, was entitled to maintain his action upon either count of the declaration."

EDITORIAL NOTES.

INCIDENTS IN THE SIEGE OF PARIS. — From one of the interesting letters of the Paris correspondent of the *Boston Courier*, we glean a few facts which will show the risks run by scientific men during the latter days of the siege. The bombs fell thickest on the left bank of the Seine, in the neighborhood of the Pantheon, where the colleges and seminaries are situated. "In one case, a shell drops into a lecture hall, while a professor is occupied with his class; it bursts, no one is injured, and the lesson proceeds. Daubrée, the famous geologist, who is largely occupied on the commission for the defense of the city by all chemical aids, is seated in his study; a bomb enters, rolls under a table, and remains there. The celebrated Abbé Moigno leaves his library for a few moments to post a letter; on his return, he discovers his furniture smashed and his valuable books burning, from a shell. Another falls in the chemical laboratory of the College Rollin, and would have been serious, only the chemicals had been previously removed. The Botanical Garden of the Medical School, where Buffon wrote, and Cuvier and Jussieu worked, has been torn up by the bombs. The Jardin des Plantes has its admired green-houses destroyed, its invaluable collection of exotics ruined." We may well rejoice that this devastation was checked before it had gone any farther. The mischief already done by war — which is but another name for barbarism — is almost irreparable, but it might have been much worse.

POLITICAL ZOÖLOGY. — The same journal laughs at the New York *Times* for confounding "that same old coon," which used to be so popular as a party symbol, with the 'possum. The *Times* had said, "The *'possum or coon* has long been recognized as an emblem of cunning;" but, as the *Courier* remarks, "the truth is that the opossum resembles the coon about as nearly as the pig does the wild-cat." It is very evident that the *American Naturalist* ought to have a wider circulation.

KINDERGARTEN TEACHING. — This rational method of training young children, originated by Fröbel in Germany, is gradually growing in favor in this country. Wherever it is fairly tested, it commends itself by its results. It turns work into play for the infant learner, and at the same time makes it more thorough work. It does this simply because it "begins at the right end," recognizing the child as a child, instead of treating him as if he had put away childish things and dried up into a sort of manikin. As Miss Peabody has said, "Kindergarten culture is the adult mind entering into the child's world, and appreciating nature's intention as displayed in every impulse of spontaneous life;" while the common method is rather forcing the child prematurely into the adult world, where no healthy natural life is possible for it. Several manuals for the use of teachers under Froebel's system have appeared in this country; but the only one that seems to be really complete and satisfactory is "The Paradise of Childhood; a Practical Guide to Kindergartners," by Edward Wiebe, published by Messrs. M. Bradley & Co., of Springfield, Mass., who also furnish all the "gifts" or apparatus necessary for carrying out the system. The author of the book, having had the advantage of personal acquaintance with Fröbel, as well as a long experience in teaching according to his methods, may fairly claim to be an authority on both the theory and the practice of the system.

"DOWN EAST" SCANDINAVIA. — The State of Maine has been trying an experiment in encouraging foreign immigration. An agent was sent to Sweden, and a colony of one hundred and fourteen Swedes were induced to pay their passage to this country and settle on the wild lands of Maine, some fifteen miles from the eastern line of the State. The young settlement appears to be doing well. Some of the results are thus stated in the Report of the "Commissioner of Immigration" just printed.

"Seven miles of road have been cut through the forest, one hundred and eighty acres of wood felled, one hundred acres hand-piled, burnt off, and cleared ready for a crop, and twenty acres sowed to winter wheat and rye. Twenty-six dwelling-houses and one public building have been built.

"A knowledge of Maine, its resources and advantages, has been scattered broadcast over Sweden, a portion of the tide of Swedish immigration turned upon our State, and a practical beginning made towards settling our wild lands and peopling our domain with the most hardy, honest, and industrious of immigrants."

If the policy thus inaugurated can be successfully carried out, the next census need not show a continued falling off in the population of Maine. By *giving* one hundred acres of land to every actual settler, "Down East" may compete with the West in furnishing "free homes for the homeless." The first and most difficult step appears to have been taken, and we do not see why a steady stream of Scandinavian immigration may not flow in through the channel thus opened for it.

LITERARY NOTES.

MESSRS. HURD AND HOUGHTON have furnished a unique and very useful book of reference in the *Handbook of Legendary and Mythological Art*, by Mrs. C. E. Clement. There was no manual of the kind in the English language, though there is so much in literature and art that people of ordinary culture cannot understand without a key. The information here condensed into one cheap volume could only be found scattered through many and for the most part costly books, accessible only to the favored few; and even those, on account of their bulk, were practically useless to the traveller, who especially needs such a guide in European galleries of art. The book lacks but one thing to make it perfect, and that is a good Index.

From Fourteen to Fourscore, published by the same house, is a well-written quiet story, which will not suit the lovers of "sensational" fiction, but is certainly none the worse for that.

American Mines and Mining, by R. W. Raymond, Ph. D., United States Commissioner of Mining Statistics, is a handsome volume of 800 octavo pages, published by Messrs. J. B. Ford & Co., of New York. It furnishes a greater amount of information concerning our American mining industry, its condition, prospects, methods, and appliances, than was ever before collected in any single work. It comprises a description of all the gold and silver mining districts of the West; a careful discussion of the laws affecting their titles; a thorough essay on mineral deposits in general, their characters and classification; a full description, profusely illustrated, of mining machinery and metallurgical processes; and an appendix, with valuable tables of statistical information. Three alphabetically arranged analytical indexes, one of *Mines*, one of *Mining Districts*, and one of *Subjects*, make the vast body of information in the work readily accessible for purpose of reference.

The Recovery of Jerusalem is "A Narrative of Exploration and Discovery in the City and the Holy Land," by Captains Wilson and Warren, of the Royal Engineers, acting under the auspices and at the expense of the Committee of the Palestine Exploration Fund. This fund was the gift of Miss Burdett Coutts, and amounted to five hundred pounds. The comely volume before us (reprinted by the Appletons) gives the results of the expedition, some of which are of the highest interest and value for the new light they throw on "the most interesting of all geographies," and on many points in biblical history and archæology.

Cornell's Physical Geography, a recent addition to Appletons' list of school-books, seems to us a better manual of the subject than any other on the same plan; and the plan is one which many excellent teachers approve.

Messrs. Scribner & Co. issue a new number of their "Library of Wonders" in *Wonderful Escapes* (that is, from prison), beginning with Aristomenes the Messenian and ending with Stephens the Fenian; also Vol. III. of Max Müller's *Chips from a German Workshop*, which is as good as its predecessors, and Vol. I. of *Curtius's History of Greece*, an admirable work, to be completed in five volumes uniform with *Mommsen's Rome*.

The Harpers have just published *The Apple Culturist*, by S. E. Todd; "a complete treatise for the practical pomologist; to aid in propagating the apple and cultivating and managing orchards; illustrated with engravings of fruit, young and old trees, and mechanical devices employed in connection with orchards and the management of apples." The author is well known by his *Young Farmer's Manual* and other works in the same line.

Rawlinson's Manual of Ancient History ought to have been reprinted sooner, and the Harpers have done teachers good service in furnishing a neat and cheap edition of it. It is an important accession to their valuable list of educational histories.

Messrs. Lindsay and Blakiston have now ready *The Change of Life in Health and Disease*, by Dr. E. J. Tilt, from the third London edition, in which the original work is much expanded. In its present form it is commended by the *Lancet* as "the best work on the subject of which it treats." Also, the second edition, enlarged, of *Byford on the Uterus*, a standard work in an improved form, both internally and externally.

Another valuable addition to the library of the gynæcologist is Dr. H. R. Storer's *Insanity in Women*, being his paper on that subject communicated to the American Medical Association, now reprinted from their "Transactions," at the request of many physicans. Messrs. Lee and Shepard have issued it in a neat little volume.

Mr. H. C. Baird has just published *A Complete Guide for Coach Painters*, translated from the French of M. Arlot, of Paris, by A. A. Fesquet, with an appendix containing information respecting the materials and practice of coach and car painting and varnishing in the United States and Great Britain. The publisher will send it, postpaid, to any address, on receipt of $1.25.

Prof. G. F. Barker's *Elementary Chemistry*, published by C. C. Chatfield & Co., New Haven, is one of the very few American manuals that represent the present state of chemical science. It has been received with much favor, and is already adopted in several of our leading colleges. The illustrations and the typography are excellent. We regret that the author did not use the nomenclature adopted by Prof. Cooke, Rolfe and Gillet, and Cooley in their text-books — the only other American books that are up with the times in chemistry — as well as by Miller, Williamson, and many other English writers. We cannot learn to like such forms as *potassium iodide*, *sodium nitrate*, etc., and we wonder that authors who write *nitric* and *nitrous*, *mercuric* and *mercurous*, etc., do not prefer *potassic*, *sodic*, etc., even in cases where two sets of adjectives are not needed. We thus get one uniform rule for all these names (instead of a rule and a "modification," as in Prof. Barker's system), and we avoid the awkward and harsh use of nouns as adjectives.

All these books are for sale at Noyes, Holmes, & Co's., 117 Washington St.

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

THE *American Journal of Science and Arts* for March contains the following articles: On the Discovery of Actual Glaciers on the Mountains of the Pacific Slope, by Clarence King; On some Rocks and other Dredgings from the Gulf Stream, by S. P. Sharples; Calorimetric Investigations, by R. Bunsen; On the Porcelain Rock of China, by Baron von Richthofen; Notes on Granitic Rocks, Part II., by T. Sterry Hunt; On the Geology of the Eastern Uintah Mountains, by O. C. Marsh; On the System of the Batrachia Anura of the British Museum Catalogue, by E. D. Cope; On Foraminifera from the Gulf and River St. Lawrence, by G. M. Dawson; Descriptions of New and imperfectly known Ascidians from New England, by A. E. Verrill; with Scientific Intelligence, etc.

The *Journal of the Franklin Institute* (Phila.) has been added to our Clubbing List, and is also advertised in this number of the JOURNAL. This standard Scientific Monthly has entered upon its forty-third year, and the numbers already issued fully sustain the high reputation it has gained in the past. It has long been "the favorite organ of our practical scientists," and in the hands of its present editors it is not likely to lose that honorable distinction. In Europe no American journal of science has more authority and influence.

The *Scientific Press*, of San Francisco, is the largest and handsomest illustrated journal published on the Pacific coast, and in no respect inferior to anything of its class in the country. The subscription price is *four dollars* a year, and we can furnish it *with the* JOURNAL on the same terms. The *Pacific Rural Press* is a new illustrated agricultural paper, issued by the same publishers, in the same style, and at the same price. We commend it to all who are interested in the development of the natural resources of California, which appears to be the El Dorado of the farmer as well as of the gold-seeker.

The School Laboratory of Physical Science is the title of a new quarterly "devoted to the thorough teaching of physical science in schools of all grades," published at one dollar a year, under the editorship of Prof. G. Hinrichs, at Iowa City, Iowa.

The *New York Medical Journal* for March has original communications by Prof. Austin Flint, on the Pathological Relations of the Gastric and Intestinal Tubules; by Prof. Geo. T. Elliot, on Bloodletting; and by Dr. R. H. Derby, on Color-blindness, and its Acquisition through the Abuse of Alcohol and Tobacco. The Clinical Records include Cases of Tracheotomy in Croup, with Recovery; Poisoning by Strychnine, treated successfully with Bromide of Potassium; Injury of the Hip-joint; etc., etc.

The *American Practitioner* has elaborate papers by Prof. W. A. Hammond, on Multiple Cerebral Sclerosis; and by Prof. L. P. Yandell, on Food in Health and Disease; with Reviews, Clinic of the Month, Notes and Queries, etc.

The *Boston Medical and Surgical Journal* for March 2d, has a valuable article by Prof. W. W. Greene, on Some Peculiar Cases of Ovariotomy; with the Description of a New Method of treating the Pedicle (illustrated with several woodcuts).

The price of the *American Journal of Obstetrics* will be $5.00 a year hereafter. The quarterly numbers are now twice as large as they were at first, and the increase in price is small in proportion. The Fourth Volume will begin in May, 1871. Messrs. W. Baldwin & Co. offer the three completed volumes, *bound*, for $12.00 to new subscribers.

We would call attention to the advertisement of the London *Chemist and Druggist*, and the very low terms on which we are enabled to furnish it — $ 2.00 a year, *post free*, or $2.50 *with the* JOURNAL. Each number contains (aside from some forty pages of advertisements) thirty-two royal octavo, double-columned pages of reading matter. It ought to have a large circulation in this country.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers.*

A. E. S., PROVIDENCE, R. I. The lecture of Prof. Chandler before the American Institute was incorrectly reported in the *Tribune*. The Professor is far too sensible, well informed, and careful, to recommend the use of galvanized iron pipes for water conduction. He is quite explicit in his approval of the "tin-lined lead pipes," and entertains views regarding their safety in which we do not coincide. It is possible that further experiment and observation may modify his opinions somewhat. He informs us by letter that his lecture will soon be printed in correct form.

G. J. C., WATERBURY, VT. Zinc evaporators, conductors, stirrers, and the like, should not be employed in the manufacture of maple-sugar, as there is danger in their use. Vessels and implements constructed of iron and tin are better, safer, and quite as cheap. We must learn to discard this metal zinc from household and other uses where food substances are liable to be poisoned by contact with it.

E. S., NILES, MICH. Dr. N. N. Hays, of this city, sends us the following, which he states has remarkable efficacy in relieving tooth-ache and neuralgic pains in the gums and face.

Mix Chloroform, 2 drachms,
Tr. Aconite Root, $1\frac{1}{2}$ do.

For simple tooth-ache, a pellet of cotton wet with the liquid and inserted in the cavity of the tooth is sufficient; for neuralgic pains, paint the parts affected, and relief is afforded. Tincture of Aconite must be used with care, as it is poisonous.

A. D. D., GREENUP, KY. A mixture of equal parts of lime-water and pure sweet oil we have found to be the most efficacious remedy for "burns and scalds." The suffering parts should be covered with the mixture, and over it place clean cotton, and bandage lightly.

B. A., LOWELL, MASS. An English law was passed in 1666, requiring that all shrouds should be constructed of *wool.* This law was amended in 1680, requiring that all persons except those dying of the plague should be buried in shrouds made of pure wool, under a penalty of £5. It was not until 1814 that this most absurd law was repealed.

W. A. P., CATLETTSBURG, KY. The circular you send giving recipes for catarrh, deafness, etc., is one of the vile documents issued by impostors, who are flooding the country with their advertisements. At the present time the mails are carrying an immense amount of very plausible, but deceptive circulars and letters, and the injury and loss sustained by the community through this means is very great. There are thousands of these worthless vagabonds scattered through the country whose whole business is to devise and conduct schemes for fleecing credulous people through the mails. Sometimes they personate women, sometimes clergymen, at other times lawyers. They issue medical circulars, circulars for lotteries, counterfeit money, business chances, etc. Now take our advice; *commit to the flames instantly* everything you receive through the mails coming from strangers, or those who have no right to address you. If you do this, you are safe.

A. B. S., ORONO, ME. We have not read any of Dr. Dio Lewis's books; but if, as you state, he recommends in one of them the use of galvanized iron pipes for the conduction of water, he gives bad advice. It shows that he is not acquainted with the subject he is considering, and his views are not entitled to weight. Dr. Lewis is undoubtedly good authority in calisthenics, but upon points involving chemical knowledge and experience he is less qualified to give advice.

G. O. L., BOSTON, MASS. What are called safety-lamps for burning naphtha we cannot recommend. They may be the cause of accidents of a serious nature in families, as from their supposed safety highly inflammable liquids will be introduced, where they could not otherwise gain entrance. There are no safety-lamps in the market that can protect individuals and families from the dangers of bad kerosene and naphtha. Some of them with wire gauze tubes, and coverings to orifices, may in a measure protect from lamp explosions, but this is comparatively a small matter. The great danger in the use of the light inflammable liquids is in their liability to take fire when a lamp is overturned or broken, or when the liquid is turned from the containing vessel into the lamp. It is the dreadful burning resulting from the inflammable nature of the fluids that renders them so dangerous. No family can introduce a single ounce of benzine, gasolene, "Sunlight Oil," "Danforth's Oil," etc., into their dwellings without great hazard, no matter what vessels they may employ to hold or burn the liquids. Good legal kerosene needs no unusual protection, as it can be burned in any common lamp with safety.

W. B. S., SPRINGFIELD, MASS. Troublesome dandruff may be removed from the head by the use of a weak solution of borax in water, or by a wash made by adding half an ounce of strong ammonia to a pint of water.

N. S., ALBANY, N. Y. Coal-ashes are worth applying to the land when much wood or charcoal has been used for kindling purposes. In many families from half to a whole cord of wood is used during a winter in stoves, furnaces, ranges, etc., in connection with coal, and the resultant ash has considerable value, and should be saved and spread upon grass lands in the spring.

P. R. W., NEENAH, WIS. It is an error to suppose that air, in passing over red-hot iron, is decomposed to any considerable extent. If all the air that comes in contact with the red-hot fire pot of an ordinary stove was chemically changed, the oxygen uniting with the iron, the pot would fall to pieces from being turned into rust, in forty-eight hours. From sanitary considerations, heating surfaces should never be allowed to reach such high temperatures. The air is rendered oppressive, and perhaps its electrical conditions are so changed as to exert an unhealthy influence upon the animal organism.

D. S. B., WILMINGTON, N. C. Kapnophyte is the term applied to a substance alleged to possess fertilizing properties. We think it is prepared in your State, and is made by burning leaves, straw, etc., and allowing the smoke to pass into, and become fixed in earth, sods, and peat. As at present advised regarding this process, we do not have a very high opinion of its value. The volatile products of combustion, under ordinary conditions, have no fertilizing qualities, and smoke is simply the unconsumed minute particles of woody fibre conveyed upward by rarefied air. When wood is distilled or burned at low temperatures, a new class of bodies are formed, such as tar, acetic acid, kreosote, etc., but they are not to be classed as manurial agents. The process does not appear to have much to commend it to the attention of farmers.

L. M. N., NORTHAMPTON, MASS. You can obtain Lakeside seed corn and seed wheat of Messrs. Parker & Gannet, No. 49 North Market Street, Boston. The number of those who applied for seed corn and wheat was so large we could not give them attention, and this has led to placing what we had to spare in the hands of the seedsmen named, who are honorable gentlemen, and will deal fairly by every one.

N. T., MANCHESTER, N. H. We must decline to answer your numerous questions. Please remember that every moment of our time is occupied, that we cannot make investigations and answer inquiries unless they are of interest to our readers. The number of letters that are received, asking questions, is very great, and it is impossible to give attention to all of them.

J. V. C., NEW YORK, N. Y. It should be remembered that the composition of nitric acid was totally unknown in 1784. That most eccentric philosopher, Cavendish, discovered the acid about that time during his experiments upon the composition of air, but he did not know what it was. In exploding mixtures of the gases, hydrogen and oxygen, by the electric spark, the acid was produced, and found in the dew which covered the vessels in which the explosions were made. The great men of the age, Priestley, Watt, Lavoisier, Cavendish, and even La Place, were confused and led astray by this phenomenon.

D. E. O., BURLINGTON, VT. Grapes can be dried so as to form raisins in this part of the country, but it requires great care. During the last autumn, which was unusually dry and warm, we manufactured some most excellent raisins, and with but little trouble. The varieties of grapes used were Black Hamburgs, Grizzly Frontenacs, Israella, and Adirondacks. The grapes to dry must have extraordinary saccharine qualities. Raisins are made in considerable quantities in California.

S. N., JERSEY CITY. Good sound fresh wheat ground in a grist mill forms the best flour for making family bread, but this cannot always be obtained in cities. Millers are quite apt to grind into "Graham meal" their poorest wheat, such as will not make white sweet flour. For the difficulty you mention, bread formed of two parts sweet flour and one part of bran is excellent. A large part of the numerous cases of obstinate constipation can be wholly or in part removed by a free use of bread prepared in this way. The bread is really delicious if well made. Some flour manufacturers prepare a cleaned bran for dietetic purposes which is very nice. That prepared by Davis and Taylor, Lawrence, Mass., and put up in small bags, we have found to be clean and sweet.

"HUXLEY FOR A PENNY." Several correspondents inquire how they can obtain the Series of Lectures mentioned under this head in the last JOURNAL. The five lectures are published for *sixpence*, by Mr. John Heywood, Manchester, Eng., under the title of "Science Lectures for the People." The book would cost twenty-five cents here, and we presume the English publisher would send it post-paid on receipt of that sum in currency. The Appletons (New York) announce "Science Lectures for the People, by Huxley, Roscoe, etc.," which is probably a reprint of this little book.

C. S., BOSTON. Your communication will appear in our next, with a few comments for which we had not space this month.

Medicine.

PHYSICIANS AND APOTHECARIES.

SOME time since Dr. J. H. Hobart Bu[...] President of the King's County (N. Y.) Med[...] Society, sent us a copy of his admirable Add[...] delivered before the society, upon the "Relat[...] subsisting between Physicians and Apothecari[...] This Address abounds in good sense, and i[...] fair, impartial discussion of an important s[...] ject. Regarding unofficinal remedies the do[...] expresses the following views: —

A prominent apothecary has lately told [...] public, through the columns of the press, tha[...] borders on quackery whenever a physician or[...] anything not embraced in the United States Ph[...] macopœia. This, to my mind, is simply ridicul[...] for several reasons: 1. Because the Pharmacop[...] is in no sense an authoritative work, though [...] excellent guide, to which we should largely adh[...] 2. We are bound by the Hippocratic oath, and [...] every principle of humanity, to direct for our [...] tient anything under heaven which will, in [...] opinion, most quickly restore him to health. [...] Common sense will not justify the assumption t[...] the Pharmacopœia contains all the therape[...] agents which are likely to prove of service. E[...] little time ago it is that we had no bromide [...] potassium, no bromide of ammonium, no carb[...] acid! — and does any one here suppose that [...] next decade will be less prolific in discovery th[...] the last? 4. To restrict the physician to the Ph[...] macopœia, is to mistake the very object and des[...] of that work, which is, that it should contain su[...] articles, and *such only*, as have been used, tri[...] and proved; and are we prepared to seal up t[...] record, and to declare to the world that our sea[...] after remedies has ceased forever — though canc[...] and phthisis, and tetanus, and hydrophobia st[...] stand on the list of the incurable? It is, howev[...] a proposition from which scarcely any one will d[...] sent, that a physician should under no circumstanc[...] write for a secret nostrum.

WRITING PRESCRIPTIONS IN LATIN.

Physicians have been accused of pedantry [...] cause they prescribe in Latin, and it has also be[...] said that they do this to keep professional kno[...] edge from the common people. Such criticisms [...] founded in ignorance. If we discard Latin, whi[...] is the language common to scientific men all o[...] the world, what shall we adopt in its stead? Sh[...] it be the English? A German or French apot[...] cary, learned in the art, may read our vernacu[...] expressions so imperfectly as to mistake our mea[...] ing altogether. Besides this, the Latin names [...] remedial agents are generally unmistakable in th[...] reference to the particular article intended, wh[...] the English is exceedingly prolix — the same arti[...] having half a dozen names, and often the sa[...] name applying to two or three different articl[...] Custom sanctions many a misnomer, and the uned[...] cated ask for a glass of soda-water, little dreami[...] that a solution of carbonic-acid gas in water is t[...] thing they want; and the thirsty servant-girl wh[...] drank the *salts of lemon* was greatly surprised [...] being told that she had fatally poisoned hers[...] with oxalic acid.

WHAT HAS THE PHYSICIAN A RIGHT TO DE[...]MAND OF THE APOTHECARY?

"Doctor," said a patient for whom he had ju[...] prescribed, "does it make any difference where [...] get this?"

"Why, yes," said the doctor. "I'd a little rathe[...] you wouldn't go to the corner grocery for it; an[...] yet," continued he, "you might as well go there [...] to some of the so-called apothecaries, for a window[...]ful of bottles of colored water is no more evidenc[...]

, the competency of the proprietor to compound ...t prescription, than the word *Doctor* painted ...n the front of a house is evidence that he who ...s within has a scientific medical education." ...ell, then, in the solution of this question — "Doc..., does it make any difference where I get this?" ...is involved the whole subject before us. We ...d that it makes so much difference, that we are ...duty bound to demand that the proprietor of ...ry pharmacy, and every clerk who is, under any ...cumstances, allowed to dispense medicines, shall ...practical druggists and graduates of some legal ...reliable college of pharmacy. It seems to us ...reasonable that the law should absolutely re...ct the compounding of prescriptions to such ...sons. Such a law, properly enforced, would im...liately divide our apothecaries into two classes, ...ely, pharmaceutists and medicine-vendors — and ...leads me naturally to the subject of the next ...most desirable reform. Medicine-vendors will, ...ourse, make and sell secret nostrums *ad nau...a*; but is it too much to ask that the scientific ...rmaceutist — the physician's help-meet and co...rer — should ignore a traffic so ignoble? Why ...uld our prescriptions be dispensed by the very ...who engage most extensively in the encour...nent of the vilest quackery? It is an incon...ty which ought not to be longer tolerated.

...gain, we have a right to demand that, in each ..., the terms of the prescription shall be rigidly ...ered to.

... teacher in the College of Pharmacy is quoted ...aving said that, if any particular manufacturer's ...aration were written for, the apothecary was ...ified in substituting his own or any other as ..., unless it were an article of unusual importance; ...if he did not his neighbor would, and he would ...ronounced a poor druggist, while the neighbor ...d get the credit of being all right. I only refer ...is to say that it is pernicious teaching, because ...hysician alone must judge of the "importance" ...e article in any given case. Equally pernicious ...to endeavor to throw the responsibility of a sub...ion upon the person presenting the prescription ...ying: "We haven't Skidmore's, but we have ...ins's, which we consider as good, if not better." ...doctor wrote for Skidmore's, and the apothecary ...l be in duty bound to refuse to put up Perkins's ...if the patient *begged* him to do so. The apoth... cannot know, and has no right to assume, that ...octor has not a substantial reason for his pref...e. With the better class of apothecaries no ...nent is needed to show the necessity of comply...ith the exact terms of the prescription, but we ...to restrict the prescription business entirely to ...etter class. Only the day before yesterday, a ...ription of mine, which was designed to be taken ...eber Brothers, was accidentally carried to a ...the proprietors of which are strangers to me. ...writing was plainly, "℞. Pulv. Doveri, gr. x. ... — *Take the powder in a little syrup.*" The ...ecary put the Dover's powder into four or five ...ms of syrup, numbered the vial, put my name ...the label, and sent it to the patient without ...lirections whatever. The patient, not being ...o communicate with me, presumed the dose ...teaspoonful, and not daring to repeat it, had ...t uncomfortable night. I saw the apothecary ...day, and his only excuse was, that he thought ...ld be so much more convenient for the patient ...nixed the powder with the syrup. There is ...thing as answering the letter of the prescrip...vhile sinning against its spirit. To illustrate ...example from real life, a patient whom I had ...ed to use no sugar, took my prescription for ...tic sulphuric acid, ten drops to be taken in a ...assful of cold water. The apothecary offi... remarked, as he handed the vial to the ser... "Tell Mrs. Blank she had better take a little sugar with each dose of that." Idle conversations are occasionally indulged in between the apothecary and the messenger who calls for the medicine, the subjects being the patient, the disease, and the doctor; and I only mention it to suggest that, as erroneous inferences are generally drawn, and such conversations sadly misrepresented, great discretion is necessary.

HYDRATE OF CHLORAL.

A FEW weeks ago Mr. F. Ripley of Avon, Conn., died suddenly from, as was supposed, the effects of a drug administered as hydrate of chloral. Dr. Geo. F. Lewis, of Collinsville, the attending physician, in the following brief communication presents some of the facts connected with the case: —

During the last week in January, 1871, I gave Mr. Ripley, of Avon, a prescription of which the following is an exact copy: —

Hydrate Chloral	℥iij.
Aqua	℥ss.
Syr. Tolu	℥j. Mix.

Sig. Teaspoonful on retiring; repeat in an hour if necessary.

It was filled at the drug store of F. J. Smith, of Collinsville, and was used as directed with the best results. The chloral I supposed to be of your manufacture; and here allow me to say I have thus far used chloral from your laboratory, always with the best success, and without the least unfavorable symptom in any case. The supply being exhausted, Mr. Ripley sent the prescription to New Haven, and on retiring took the usual dose, one teaspoonful, and died within thirty minutes. A post mortem examination, made by Prof. L. J. Sandford, of New Haven, showed no cause for death except slight fatty degeneration of the heart. One half the contents of the vial from which Mr. Ripley took the last dose was sent to Prof. Johnson, of the Sheffield Scientific School, New Haven, for analysis, and found to contain sugar, water, bals. tolu, and hydrate chloral. The chloral was of Liebreich's manufacture, and stronger than that of American make. From the peculiar results obtained from experiments with chloral from other sources, and from the perfectly healthy condition of Mr. Ripley at time of death (except the fatty degeneration of heart), there may be and is some doubt as to the real cause of his death, whether it was from an overdose of the chloral, or perchance from some substance which may have escaped Prof. Johnson's observation.

Remarks. — A mixture of hydrate of chloral of the character described would present some obstacles to exact analysis. Of course the sugar, water, and tolu would be readily recognized, but it is absurd to suppose that Prof. Johnson or any other person could determine whether the chloral hydrate was manufactured by Liebreich or some one else. The important point to learn is, was the chloral *pure* or *impure*? and this ought to be decided if possible. The case demands investigation, and we hope Dr. Lewis and other medical gentlemen will not rest until every means is exhausted for ascertaining the character of the agent administered.

INFLAMMABILITY OF PYROXYLINE.

IT may not be very generally known among dentists what an extremely inflammable substance pyroxyline is, and how easily a set of teeth may be destroyed by coming in contact with anything that is ignited. A short time ago an acquaintance of mine came up to the office in the evening, and I took him into the laboratory and showed him the new kind of base I was using for artificial teeth. We each sat down and smoked a cigar. Just as we had entered the hall, about to leave the office, on turning round we observed the room we had just left brilliantly illuminated, almost equal to that produced by the magnesian light. I rushed back and found my pyroxyline plate in a blaze, and being rapidly consumed. On making an examination, I discovered that when we left the room I happened to lay a lighted cigar in close proximity to the case of teeth, which set it on fire. It will require some degree of care on the part of those using this material not to allow lighted cigars, matches, or anything of that sort, to come in contact with it when out of the mouth. It might prove somewhat hazardous for an individual wearing a set of teeth made of this material to accidentally put *the wrong end* of a lighted cigar in his mouth! — *Canada Journal of Dental Science.*

Remarks. — The substance called *pyroxyline* is a transparent horny material manufactured from gun-cotton by partially dissolving it in a mixture of ether and alcohol. It is essentially *dried collodion*, and the manufacture differs from that substance in using only a sufficient quantity of the solvent to form a pasty mass, which, as it stiffens by the evaporation of the ether, is rolled or pressed out into plates. This, tinted with a pigment, and put in proper form, constitutes a new base for attaching artificial teeth. It is, indeed, very combustible, burning with an ardent, almost explosive flame, and throwing off ignited filaments and sparks. We do not think it liable to spontaneous ignition; but in using it, dentists should be very careful that flame or sparks do not come nigh it. Of its value or usefulness for the new purpose to which it is applied, we are not prepared to speak. It may be regarded as insoluble in the salivary and gastric secretions, and we think it can exert no poisonous influence upon the system.

MEDICAL MEMORANDA.

STATISTICS OF CANCER. — In an article on cancer, in the *Scientific Press*, of San Francisco, Dr. Fraser of that city says that the disease prevails to a much greater extent than most people suppose. "In England, outside the city of London, the deaths from cancer have been known to average 2,332 per year. Estimating London in the same ratio, the deaths from cancer in England alone would amount to nearly 3,000 per year. As the prevalence of the malady does not seem to be determined by local influences, it is quite reasonable to suppose that the English statistics show a fair average. Such being the case, the total number of deaths annually from cancer would amount to more than 150,000.

"The English statistics show that three fourths of the cases are among females. This difference is due to the extraordinary frequency of cancer of the breast and of the reproductive organs. The disease may make its appearance in any organ or tissue of the body, in either sex, and at any period in life, yet it occurs most frequently between the ages of 40 and 55."

INCREASE IN MORTALITY DURING THE SIEGE OF PARIS. — The usual weekly bulletin of deaths shows the number to be between 1,000 and 1,200. In the last weeks of the siege it rose to 3,000 and over. This was not due to the prevalence of any epidemic, but to the scarcity of food and fuel, which told heavily on old persons, invalids, and children. Moral causes, too, had their effect. Lung diseases were very common and mortal among those advanced in years.

POPULAR RECIPES FOR DYSPEPSIA. — Voltaire suggested as a remedy for dyspepsia the taking of no other nourishment than the yolk of eggs beaten up with the flour of potatoes and water.

Sir John Sinclair has the credit of the following

modification of the great Frenchman's recipe: — Beat an egg in a bowl, and add six table-spoonfuls of cold water, mixing the whole well together; then add two table-spoonfuls of the farina of potatoes (or potato starch), to be mixed thoroughly with the liquor in the bowl; then pour as much boiling water as will convert the whole into a jelly, and mix well. It may be taken either alone or with the addition of a little milk and pulverized white sugar, not only for breakfast, but, in cases of great stomach debility or in consumptive disorders, at the other meals. The dish is light, easily digested, extremely wholesome and nourishing. Bread or biscuit can be taken with it, as the stomach gets stronger.

History of Quinine. — In 1803, Dr. Duncan, of Edinburgh, had detected some of the active principles of cinchona bark. The great pharmaceutical discovery of quinia, however, was made in 1820, by Pelletier and Caventou, pharmaceutical chemists, of Paris. In 1823, Henry and Delondre, of the same city, announced the existence of quinidia. As the therapeutical effects of Peruvian bark had already become so well known, it could not be long before quinia must come into general use, and such was really the fact. Magendie and Chomel, of France, were active in introducing the alkaloid into practice in their own country, and Dr. Elliotson and others, in England; and from those two great medical centres its use spread rapidly over the rest of Europe and the Western world.

The Cause of Sleep. — Dr. E. Sommer considers that sleep is the result of a *deoxygenation* of the organism. The blood and the tissues possess the property of storing up the oxygen inhaled, and then supplying it in proportion to the requirements of the economy. When this store of oxygen is exhausted, or even becomes too small, it no longer suffices to sustain the vital activity of the organs, the brain, nervous system, muscles, etc., and the body falls into that particular state which we call sleep. During the continuation of this deep repose, fresh quantities of oxygen are being stored up in the blood, to act as a supply to the awakened vital powers. Rest produces, though in a less degree, the same effect as sleep in reducing the expenditure of oxygen.

Neuralgia. — A correspondent of the *Lancet* says: "A few years ago, when in China, I became acquainted with the fact of the natives, when suffering with facial neuralgia, using oil of peppermint, which they lightly applied to the seat of pain with a camel-hair pencil. Since then, in my own practice, I frequently employ this oil as a local anæsthetic, not only in neuralgia, but also in gout, with remarkably good results."

Thin Sheet Lead instead of Lint in Wounds. — Dr. Burgrease has so employed sheet lead, and states that it feels soft and cool to the wounded parts — its use entirely superseding that of lint. The formation of a very thin layer of sulphuret impedes putrefaction and the development of small organisms.

Cotton Respirators. — Dr. Jouglet, taking the hint thrown out by Prof. Tyndall, has experimented upon the use of cotton respirators, and states that by their application the disease known as miners' anæmia, and also the dangers of the effects of lead, copper, and mercury to those who have to handle these metals, or work in vapors or dust thereof, may be prevented.

"A First-rate Notice." — The *Medical Gazette* gives the following generous "puff" to one of the Smith family: —

"We are in receipt of a modest proposition that we should take two dozen bottles of 'Nature's Hair Restorative' as an equivalent for a six months' advertisement thereof, and the insertion in every issue of an editorial puff, a stereotyped assortment of which is kindly furnished. We are also urged to send a three-cent stamp for a 'Treatise on the Human Hair, which is worth $500.00 to any person.' When we state that the preparation in question is the invention of 'Dr.' (not 'Professor,' for a wonder) G. Smith; that it restores gray hair to pristine darkness, but is 'not a dye;' and that it cures headache, 'humors,' and cutaneous eruptions — we have probably said all that our readers care to hear; unless, perhaps, the members of the Dermatological Society should wish to save $499.97 in the purchase of the $500.00 treatise aforesaid, in which case we shall be happy to transmit their order."

VALUABLE FORMULÆ.

Neuralgia. — M. Bertrand, Paris, has used the following ointment with perfect success, in neuralgia, when other remedies had been tried without effect:

℞ Veratriæ	. . . . . .	grs. v.	
Morph. Sulph.	. . . . . .	grs. iij.	
Adipis	. . . .	℥ i.	M.

Sig. Rub painful parts with the ointment frequently, when the paroxysms of pain are at their height, and as often as they require. Two or three frictions suffice, in a majority of cases.

Local Paralysis. — Dr. Brown-Séquard uses the following formula in local paralysis: —

℞ Strychniæ Sulph.	. . . . .	grs. ij.	
Chloroform	. . . .	℥i.	M.

Apply half, night and morning, by brisk friction to the part.

Substitute for Dover's Powder. — Dr. Chapin (*Medical and Surgical Reporter*) has not used Dover's powder for twenty years, much preferring his substitute as more palatable and effective; which is as follows: —

℞ Opii. pulv.	. . . .	ʒ i.
Ipecac, pulv.	. . . . . .	ʒ ss.
Camph. pulv.	. . . .	ʒ ij.
Saccharum	. . . .	ʒ iv.

Mix thoroughly. This contains one grain of opium in eight grains of the powder. He frequently uses morphia, in due proportion, instead; or omits the opium altogether when contra-indicated.

Treatment for Tape Worm. — Dr. Wm. M. Turner remarks that the following plan for expelling either the tænia lata or tænia solium never fails. First, at bed-time give the following cathartic: —

℞ Pulv. Potass. et Rhei. aa	. . .	grs. x.	
Hydr. Chlo. Mit.	. . . . .	grs. ii.	M.
Chart.	. . . .	No. 1.	

The next morning, after a *decided catharsis*, and on an empty stomach, give —

℞ Kooso, pulv.	. . . . . .	ʒ iv.	
Aquæ	. . . .	f. ʒ ix.	M.

Sig. Take in a quarter of an hour's time, in three doses. The action is speedy, and the danger none.

Turpentine in Infantile Convulsions. — When convulsions continue in colicky children, and are not relieved by the warm bath, injections of warm water, brandy, or chloric ether, with an alkali, Dr. Graves recommends turpentine to be given: ℞. Ol. terebenthi, ʒj.; ol. ricini, ʒiv.; mist. acaciæ, aq. cinnamoni, *aa.* ʒiij. M. ʒj. tertiâ quâque horâ. This acts on the bowels, and produces a copious discharge of urine.

Compound Beeswax Pills. — The *Druggists' Circular* gives the following formula for these pills, which are recommended for improving the voice of public speakers: —

℞ Yellow beeswax	. . . . .	2 drachms.
Balsam copaiva	. . . .	2 "
Fuse, and add liquorice root (powdered)		4 "

Mix, and make 240 pills; two to be taken three times every other day.

EXPLOSIVE PRESCRIPTIONS.

Whether a physician is ever justified in "blowing up" a druggist may possibly be an open question, but he certainly ought not to do it by means of a prescription. An English pharmacist received the following: R. Argenti ox. gr. iss.; ext. nuc. vom. gr. 1-6; morph. mur. gr. 1-32; and the pills prepar by the formula, with confection of roses, soon aft wards exploded with evolution of considerable he Permanganate of potash will sometimes act similarl An analogous case lately occurred at Nottingha England, and excited some interest at the time. T following prescription was made up: R. Arg. ox. g xlviii.; morph. mur. gr. i.; ext. gent. q. s. M. Ft. p xxiv. The lady who received the pills, which we silvered, put the pill-box into her bosom. In thr quarters of an hour a severe explosion took plac her clothes were burnt, her right breast severe scorched, and smoke issued freely from beneath h dress. A troublesome burn on the breast remain for treatment. It has long been known that pil made of oxide of silver and creosote (or carbol acid) are liable to become very hot, or even to i flame, and a dispenser has been astonished by seein the lid of a box which contained such pills sudden blown off, and the pills sent rolling over the counte

The following prescription gave rise to a viole explosion on being made up by trituration in a roug Wedgwood mortar: R. Pot. chlor. oz. iss.; ac. ta nici, ʒ iss.: olei gaultheriæ, gtt. xx. M. Again mixture of chlorate of potassa and catechu, pr scribed as a dentrifice, occasioned a violent expl sion in the mortar in which it was rubbed. Erhard explosive powder for shells is composed of equ proportions of tannin and chlorate of potass Lastly, a "pharmacien" received the following pr scription to dispense, namely: Pot. chlor., 8; hyp phosph. of sodium, 4; syrup, 62; water, 125 part In order to expedite matters, he vigorously triturate the salts in a mortar, and the result naturally wa that he received some wounds on the body, whil the pestle was thrown to a distance. The two salt should, of course, have been dissolved separatel These and similar reactions depend on the facili with which oxide of silver and chlorate of potass part with their oxygen to organic matter, and th consequent elevation of temperature due to the rapid decomposition of the salt.

GOOD ADVICE TO DYSPEPTICS.

If a man wishes to get rid of dyspepsia, he mus give his stomach and brain less to do. It will be o no service to him to follow any particular regime — to live on chaff bread or any such stuff — t weigh his food, etc., so long as the brain is in a con stant state of excitement. Let that have prope rest, and the stomach will perform its functions. Bu if he pass fourteen or fifteen hours a day in his offic or counting-room, and take no exercise, his stomac will inevitably become paralyzed, and if he put nothing into it but a cracker a day, it will not di gest it. In many cases it is the brain that is th primary cause. Give that delicate organ some rest Leave your business behind you when you go t your home. Do not sit down to your dinner wit your brows knit, and your mind absorbed in casting up interest accounts. Never abridge the usua hours of sleep. Take more or less exercise in th open air every day. Allow yourself some innocent recreation. Eat moderately, slowly, and of just what you please — provided it be not the shovel and tongs. If any particular dish disagrees with you, however, never touch it or look at it. Do not imagine that you must live on rye bread nor oatmeal porridge: a reasonable quantity of nutritious food is essential to the mind as well as the body. Above all, banish all thoughts of the subject. If you have any treatises on dyspepsia, domestic medicine, etc., put them directly into the fire. If you are constantly talking and thinking about dyspepsia, you will surely have it. Endeavor to forget that you have a stomach. Keep a clear conscience; live temperately, regularly, cleanly; be industrious too, but be temperate.

Familiar Science.

DIAMONDS AND DIAMOND CUTTING.

A NICE little packet, which could be carried in ne compartment of an ordinary wallet, has been pened in our presence, and the contents sub-itted to inspection. All that met the eye was collection of shining pebbles, about fifty in umber, and yet it would require at least twenty ounds of solid gold to purchase the group of ttle crystals. They are diamonds in the ugh, from the newly discovered African dia-ond mines, and thus are objects of curiosity. ' they were brought to the surface in digging our garden, we should suppose them to be agments of glass or perhaps crystallized quartz, id after a brief examination should probably row them back to the dust again. It requires i experienced eye to distinguish an uncut dia-ond from some of the common crystals found on e sides and in the beds of streams flowing from ir hills and mountains, and therefore it is not rprising that the gems remain unrecognized fields which have been many times explored 'y travellers.

The diamonds here spoken of were imported 'y Messrs. Crosby, Morse, & Foss, jewelers, of is city, and in a few weeks or months they will ive been *cut* and placed in their elegant cases, ady to excite the interest and admiration of irchasers. There is no city or town in the nited States where the difficult and interesting ocess of diamond cutting is carried on but in oston, and no other parties but the house med have ever attempted to improve imper-t diamonds, or cut the gems as they come m their native beds.

In company with Mr. Henry D. Morse, the iginator of this peculiar manufacture, we re-ntly visited the factory where the work is ne, and the hour spent in inspecting the pro-ss was full of interest. Diamond cutting has en for years monopolized by Holland, and in e city of Amsterdam some *two thousand men* e constantly employed in the industry. With e long experience, however, of these workmen, me of the finest stones are very unskillfully t, and those brought to this country have been iced in the hands of Mr. Morse to be recut d perfected.

The machinery employed in Holland for pol-ing is ponderous and heavy, the framework lding the wheels being braced and wedged, e the running gear of a country saw-mill. In e establishment in this city a small iron-top ble is used, with solid iron supports and double rings, so that the polishing wheel, being fixed the centre, revolves horizontally on a level h the surface of the table. By this ingenious vice, the work of Mr. Morse, perfect steadiness secured, and without the clumsy machinery of e Dutch manipulators a greater degree of ac-racy is obtained.

To cut a diamond is to form its surfaces so that light in passing through is refracted in a way to produce a maximum of brilliancy. The rough gems are quite dull or lustreless, and it requires consummate skill in cutting and polish-ing to secure the accuracy of angular proportion in the faces necessary to perfect results. There must be principal planes or faces, and around them a considerable number of smaller ones, all placed at correct angles, so that, by refraction, a blaze of light, every ray in harmony, may be the result. The skill of the operator is shown in his ability to bring out the *whole power* of a stone.

The diamond is the hardest of known sub-stances, and hence the inquiry will naturally arise, "How is it possible to produce mechanical effects upon a substance so refractory?" "Dia-mond cut diamond" is an old adage, and it has a practical illustration in the factory. The dust of the gem is employed to wear away the surface of those undergoing the process of polishing, and this is obtained by grinding worthless parti-cles in a steel mortar, and also the minute frag-ments obtained in the progress of the work are saved for the purpose. But these two sources of supply do not afford sufficient material to meet the wants of the industry, and consequently a substance found in association with diamonds, and possessing equal hardness, is to a large extent employed. This pebble, which has no value as a light refractor, is pure carbon, like the diamond, but it is not perfectly crystalline. It is semi-amorphorus in structure; and if it was not used for its mechanical value, it would be as worthless as a bit of charcoal. It is now worth in the market about six dollars a pennyweight.

When two diamonds are rubbed together they are mutually abraded, or worn away, and hence if we have a valuable one which we wish to cut, to develop its brilliancy, we have only to select another which by its shape is worthless, and bring this to bear mechanically upon the other, and the work goes on. The worth-less diamond may be called the tool with which the cutter elaborates the valued gem. Each is placed in cement, conically heaped at one end of two sticks of convenient handling size. The cutter is so placed in soft cement that its cutting angle can be employed to the best advantage upon the clear stone, which is similarly adjusted to present the surface to be abraded. After the cement has hardened, the workman grasps the stick, holding the cutting diamond in his right hand and that with the gem in his left, and the stones are brought together over a double metal-lic box, the inner section of which is provided with a perforated bottom, being half the depth of the outer, into which it closely fits. The parti-cles which become detached from both stones fall into the inner box, the smaller passing through the orifice, to the bottom, being fine enough to perform their functions on the polishing wheel. The coarser grains are afterwards, as we have stated, powdered in a steel mortar. Diamond cutting is slow and tedious work, and requires the utmost care and skill to accomplish the pro-cess successfully. In the Boston factory, the labor is done under the eye or immediate super-vision of Mr. Morse, who originated the industry, and who devised and constructed the machinery.

The diamond has a grain or cleavage plane, the same as most mineral or crystalline sub-stances, and hence it is possible to split or divide one into two or more parts. Sometimes a large piece is removed at once from a gem by splitting, but it is a process attended with much risk. To accomplish this after the stone is carefully stud-ied and its line of cleavage ascertained, it is placed in hardened cement, in the proper posi-tion, and the sharp edge of a steel chisel resem-bling a razor is carefully adjusted so that the division will be at the points desired, and a smart rap with a hammer is given it. Perhaps no more costly blow may be struck in any mechanical work than this, for in manipulating a large diamond, if it is unskillfully given, a gem of several thousand dollars' value may be spoiled.

After a diamond is cut, the work of polishing commences, and it is in this department that the American machinery is seen to be superior to the Dutch. This we have already described. The gem is adjusted in soft lead heaped coni-cally in a copper cup, ten times the capacity of those used upon the cement sticks in cutting. The surface of the wheel is charged with dia-mond dust mixed with oil to the consistency of thin paste. The stone and wheel thus arranged, the latter is made to revolve at the rate of fifteen hundred revolutions a minute, and the stone, placed in a heavy iron clamp, is inverted upon the wheel. Nothing but the diamond touches the wheel, it being pressed down by the weight of the iron clamp. A rather musical tone is produced by the contact, which shows that the wheel is doing its work, and that now a bright surface will be produced upon the "table" ex-posed to its action. When this is satisfactory, the operator melts the lead, releases the gem, and readjusts it so as to polish another of the faces, and in this way the process goes on until the work is completed. To attain this, however, the tables and facets are many times exposed to the wheel, and it is not until the most careful measurements and experiments are made that the gem is pronounced satisfactory. Mr. Morse has been intrusted with the manipulation of some of the most costly diamonds ever brought to this country, and in no instance have his labors re-sulted in loss or failure, a circumstance which reflects much credit upon his ingenuity and skill.

The importation of African diamonds has but just commenced, but doubtless large quantities from the new mines will flow towards this country, as we are large purchasers of the "brilliants." The market in the United States

will not put up with anything but the best. We do not purchase the largest, but the choicest, which are produced in all parts of the world. Stones of from one to five carats are always in good demand here; above that, purchasers are scarce. A seven or ten carat diamond is worth from $6,000 to $10,000, and the number of those who are willing to invest that sum in a single stone is limited. Sporting men, who keep gambling saloons, and drive fast horses, wear the largest and most costly gems; and when we notice an unusually large and brilliant one upon the person of a stranger, we instinctively regard him as belonging to the sporting fraternity.

In what is known as the "shoddy" era, during the war, when petroleum and war contracts elevated men suddenly from poverty to great affluence, large diamonds were in demand, and there were not enough of these in the country to meet it. The price of diamonds of one carat ranges from $165 to $175, but there are some "unexceptionable" ones in the market which command a higher price. Most of those who visit jewelers' stores for the purpose of purchasing diamonds, have no knowledge of the nature of the gems they seek. They do not know that a diamond, like a horse or an oil painting, is sold for its excellence or beauty. If a diamond is "off color," or even has slight flaws, they do not detect the faults. If diamonds are sought, it is important that they should be purchased of honest parties, and those who by experience are fully acquainted with their character and value.

It is certainly singular, that with the immensely increased production the gems continue to increase in price from year to year. The recent convulsions in Europe and our late civil war, in which thousands of diamond owners were reduced to penury, did not result as one would suppose, in throwing upon the market large quantities of diamonds. It is probable a few changed hands, but not enough to influence the price in the slightest degree. Large numbers of the diamonds which have been dug from the earth in the last two thousand years have been hoarded, and are not often brought to the light. They are left to dazzle unseen, in caskets and steel safes, where they are almost forgotten. A diamond worth £30,000, or $150,000, has recently been found in the African mines, and several others of a size and brilliancy which render them nearly as valuable are reported. It is highly probable that diamonds in considerable quantities will be found in the United States at no distant day. In the mountains of South Carolina and Georgia where gold exists, there are geological strata which present striking analogies to those of Brazil, Africa, and Australia where diamonds are found in abundance. A few have already been picked up in those localities, and also in California.

ANTIMONY AND ITS COMPOUNDS.

THERE are not a few metals the compounds of which are in common use, though we rarely see them in their elementary state, and know little about them unless we have studied books of chemistry. Antimony is such a metal, familiar and valuable in its practical uses, and yet quite unknown to most people in its uncombined form. The metallic antimony is an important article of commerce, but how many of our readers can describe it, or would recognize a specimen of it?

The chemical name of antimony is *stibium* (whence the symbol *Sb*, used in chemical formulæ), and *stibium* was the Latin name of a compound of the metal — the sulphide, undoubtedly — which was known to the ancients. The metal itself was not known to them, though we have seen statements to the contrary in some school text-book of chemistry. It was not until the middle of the fifteenth century that antimony was obtained in a metallic state, by Basil Valentine, a German monk and alchemist, but a diligent and enthusiastic student of natural science. There is a story that while experimenting with the new metal and its compounds, he happened to throw some of it into the hog-trough, and found that after purging the swine violently it seemed to improve their condition and to fatten them. This led him to try its effects upon some of his brother monks, but unluckily the dose proved fatal. The reader has probably heard of the quack, one of whose patients, a Frenchman, took a fancy to molasses and salt herring, and on eating them recovered from his fever; hence he ordered the same diet for his next patient, who happened to be a Dutchman, but with a very different result. The man died; and the quack made a note in his memorandum book to this effect: "Molasses and salt herring are good for a Frenchman in fever, but death to a Dutchman." In like manner, our worthy Basil Valentine concluded that his metal was good for hogs, but death to monks, and therefore named it *antimony*, or monk's-bane, from *anti*, against, and *monachus* (French *moine*), a monk. But the story was probably suggested by the name, and not the name by the circumstance given in the story, and it is therefore rejected by the best etymologists. Another derivation of *antimony* makes it from *anti* and *monos* (alone), because the metal is rarely found alone, or uncombined. But, on the whole, it is more likely that the word is nothing but a corruption of *al-ithmidun*, or *al-uthmudun*, the Arabic name for the metal.

Antimony is a brittle metal, of a bluish-white color, with a brilliant lustre. It is highly crystalline in its structure, and really beautiful to the eye; so that when we first see a specimen of it we cannot help feeling disappointed that it is practically useless in its pure state. It melts at about 830° F., and when heated to full redness takes fire and burns brilliantly, producing white fumes of teroxide. It is a pretty experiment to melt a bit of it on a piece of charcoal with a blowpipe, and then to throw the glowing globule down upon a board or a large sheet of brown paper: it bursts into myriad little beads, which roll in all directions, each leaving a line of white oxide, like the trail of a meteor, to mark its path.

Some of the alloys of antimony are of great practical value, especially the one by whose aid we are enabled to give you this account of the substance. *Type-metal* is an alloy of lead and antimony, in the proportion of about one part of the latter to four of the former. This combination is so admirably adapted to the purpose, that it is hardly probable that it will ever be superseded or materially modified. Antimony enters also into most of the common white metallic alloys used for cheap teapots, spoons, forks, and the like. The best pewter contains it, and so does *Britannia metal* in all its varieties. The office it serves in these compounds is to give hardness to the lead and tin (which are usually the chief ingredients, though bismuth, copper, and other metals a often added in smaller quantities) without re dering them too brittle.

In medicine, antimony has been employ more or less from the day when Basil Valenti is said to have given his fellow monks too "h roic" a dose of it. *Tartar emetic* is a tartrate antimony and potash, or what is called a "doub salt." It has had a somewhat varied fortune an item in the materia medica. In France for time it was illegal to use it internally, and least one physician lost his diploma for admi istering it; but it was subsequently (in 1637, believe) authorized to be used again. At th present day, many of our best physicians do n hold it in very high favor, but others contin to employ it freely, and it will doubtless be use to "serve an ejectment" upon the human stom ach for many a generation yet.

The tersulphide of antimony (or *antimonio sulphide*, according to the new nomenclature) used in pyrotechny as an ingredient in vario colored fires. The *blue* or *Bengal light*, for e ample, is made by mixing finely pulverized sal petre (6 parts), sulphur (2 parts), and antimon ous sulphide (1 part).

A detonating powder can be made by heatin strongly for several hours a mixture of 100 par of tartar emetic and 3 parts of lamp-black. Th crucible should be left to cool under a bell-glas The powder will explode on being moistene with a drop of water, and great care is necessar to prevent its exploding spontaneously.

THE LAST OF THE ALCHEMISTS.

IN the latter part of the last century, Jame Price was a distinguished amateur chemist i England, and a Fellow of the Royal Society He had a private laboratory at his residence i Guildford, where he devoted much of his time t alchemy, which still found an occasional devote even among scientific men. In 1782, Mr. Pric imagined that he had discovered a powder tha would transmute mercury and other of the base metals into gold and silver. He appears t have hesitated about giving the results of his ex periments to the public, but the chemists soon got wind of the matter through some of hi intimate friends whom he had made his confi dants. This led to a lively discussion of hi pretensions in scientific circles, and many wer disposed to accuse him of deliberate imposture To prove that he was no charlatan, Price offered to repeat his experiments in presence of a selec company of men, competent to pass judgmen upon them and above the suspicion of being i collusion with him, and arrangements were made for the ordeal. The experiments, seven in number, began at Guildford on the 6th of May, 1782, and were completed on the 25th. In all of them gold and silver were apparently obtained from mercury, and this transmutation was attested by the peers, clergymen, lawyers, and chemists who had watched the process. Some of the gold was presented to the King (George III.), who graciously consented to accept the marvelous gift. The University of Oxford hastened to do honor to the successful alchemist by conferring upon him the degree of M. D.; and a book in which he published an account of his experiments ran through two editions in a few months.

If all this were not matter of sober history, we could hardly believe that it occurred less

:han ninety years ago; but it must be borne in nind that alchemy, after its many centuries of enown as an occult science, was dying a lingering leath, and chemistry, the infant daughter of the venerable juggler, was still in its cradle. But hough the king had recognized Price as a public benefactor, and Oxford had honored him as a scientific discoverer, there were men wise enough to ee that he must be either a deceiver or selfleceived. His position and standing were decidedly against the former view. He was no needy and nameless adventurer, like most of the professed alchemists of that day, but a man of wealth and good family, who had devoted himself to chemistry out of pure love of science, and whose private character was above reproach. The case was a peculiar and perplexing one, and even now it remains somewhat of a mystery. At the time, it became the subject of controversy so earnest and bitter, that at length the Royal Society felt obliged to call upon Price to repeat his experiments in their presence, and thus prove to the satisfaction of his brother fellows the truth of his pretensions. Up to this time, we may doubt whether he was honest or not, but now it s quite evident that if he had deceived himself, he delusion is at an end, but he hopes to evade he mortification of acknowledging it. He declines to repeat his experiments, on the ground that the preparation of the mysterious powder is difficult and dangerous to health. He has found also, he says, that this method of making the precious metals, though interesting for its scientific bearings, cannot become practically useful, as he amount obtained will not cover the cost of production. In one case, as he states, it cost him about seventeen pounds sterling to prepare gold to the value of four pounds. He urged, moreover, that the experiments had already been performed before honorable and competent witnesses, and nothing could be gained by repeating hem; "for, as the spectators of a fact must always be less numerous than those who hear it related, so the majority must at last believe, if hey believe at all, on the credit of attestation." He claimed further that his character and his scientific reputation ought to be a sufficient assurance o his friends that he had not deceived them. The Royal Society nevertheless insisted that his own honor and theirs required that the experiments should be repeated, and he finally left London for Guildford in January, 1783, promising to return in a month fully prepared for the trial.

At Guildford Price shut himself up in his laboratory, distilled a quantity of laurel-water, the quickest and deadliest poison then known, and made his will. He then went to work to prepare the powder of transmutation. Six months passed away, and even his best friends began to think that he had deceived them, when he suddenly appeared in London and formally invited he Royal Society to meet him at his laboratory Guildford, on the 3d of August. A year earlier the *élite* of England had assembled to witness his wonderful alchemy, but on this occasion only three members of the Royal Society came o Guildford in response to his invitation. After receiving them with a cordial welcome, Price stepped aside for a moment, and hastily drank a flask of laurel-water. His visitors, observing a sudden change in his appearance, though they did not then suspect the cause, sent in haste for medical assistance; but in a few minutes the unfortunate man was dead.

As we have intimated, there are many who believe that the experiments of Price were an imposture from the outset; but it seems to us more probable that he was at first the victim of some unaccountable delusion, and that he had recourse to deception afterwards, simply because he had not the moral courage to confess his error after having published it to the world as a great discovery. This explanation of his conduct is not without its difficulties, but the same may be said of every view that can be taken of it, and on the whole this is the most plausible solution of the enigma.

"Thus it was," to quote the words of another, "that alchemy, among scientific men at least, in England, came to an end with the last act of a tragedy." In Germany, on the other hand, its final appearance on the stage was rather as a comedy; but that tale we must postpone to another day.

NATURAL HISTORY NOTES.

Concerning Snakes. — It is a popular error that a snake cannot kill a snake. Dr. Fayrer, in India, has been making some experiments to settle the question. He took a young and lively cobra, and allowed it to be bitten in the muscular part of the body by a krait. In ten minutes the cobra was sluggish, and in thirty-two minutes after the bite it died. The same Dr. Fayrer has found that the water-snakes of India are deadly poisonous. It was recently proposed to erect a sea-bathing establishment in the Bay of Bengal at a place where it was certain there were no sharks, but it was found that the locality swarmed with these water-snakes, which would have been quite as bad as the sharks.

At Madras the Commissioner of Police has forbidden the dancing girls to dance in the Hindu temples with cobras twined round their necks, one of the girls having died from the bite of such an animated necklace. This will be a great disappointment to the pious votary, but it is suggested that it will tend to lessen the reverence for the cobra, and thus render his extermination more probable.

The Lower Animals and their Lord. — Man may be the lord of creation, but he has some very rebellious subjects in his domain, and they give him a good deal of trouble. We read in an English paper that Major Daires, in India, has been lucky enough to shoot a tigress which in seven years had killed 140 persons in a few villages. The beast had become such a terror to the vicinage that many families had left, and a great part of the land had ceased to be cultivated.

But the insects are the most unmanageable of all the creatures not yet fully subdued by their appointed master. There is no part of the world where he is not more or less at their mercy; but in tropical regions they sometimes fairly put him to flight and reign in his stead. The United States Consul at St. Helena, in a recent communication to the State Department, reports that the white ants which have invaded the island are fast destroying everything upon it. No wood but teak, and sometimes not even that, can stand against them. Many houses in Jamestown have been fairly gutted by them; doors, windows, floors, and roofs all being eaten up, leaving nothing but the bare walls.

We forget what naturalist it was that suggested, years ago, that if man wants to get rid of insects, he must set to and *eat* them, as some savages *do* in the case of certain species of ants, worms, and spiders. But it is doubtful whether he could keep their numbers within reasonable limits in that way. The great difficulty is that we know less about them than about any other branch of the animal creation, and therefore we fight with them at a great disadvantage.

A White Elephant Captured. — This is important state news in Siam, where the chief white elephant ranks next to the queen and above the heir apparent to the throne. The papers there report that a new white elephant has just been captured, and that he has been conducted with due pomp and ceremony to the capital, where he will receive the honors and dignities to which his color entitles him.

EXPERIMENTS FOR THE SCHOOL-ROOM.

A German scientific journal gives the following experiments for the use of the teacher or lecturer: —

Combustion of Oxygen with a Sooty Flame. — Into a long-necked flask pour some benzole or oil of turpentine. Close the flask with a cork, through which two short glass tubes are passed, one of which should be of about one centimeter internal diameter, the other narrower and somewhat bent sidewards. Let the liquid in the flask be boiled, and, as soon as the vapors issue from the wider tube, ignite them; and, this having been done, pass through that tube another narrower glass tube connected with a suitable gas-holder, or other vessel, containing oxygen. This tube should be provided with a platinum burner bent upwards and fitted with a cork, which closes the opening of the wider tube. This oxygen-carrying tube is made to pass deep into the flask; and immediately after the closing of the wider tube, the oxygen begins to burn with a sooty flame, while the excess of the vapors of the boiling liquid are discharged by the narrower glass tube first mentioned.

Oxidation and Reduction, and the Resultant Change of Weight. — Take oxide of copper; make it, by means of weak gum-water, into a paste, and shape that into a cylindrical form one centimeter in diameter by three centimeters in height; dry it; ignite it gently; next reduce it by means of hydrogen to the metallic state at as low a temperature as possible; cool it in the current of the hydrogen gas; and, next, wind round the cylinder a platinum wire, the free end of which should be molten into a glass rod, so as to be used as a handle. This having been done, have ready two tubulated bell-jars — one turned with its wide opening downwards, to hold hydrogen gas, to be carried into it by a flexible tube through the tubulature; the other jar, with its wide opening turned upwards to hold oxygen. Now heat the copper cylinder (which, although very porous and spongy, has sufficient cohesion for the experiment) gently, taking care not to make it red-hot, and immerse it in the oxygen, whereupon it will become suddenly red-hot, and continue so until the oxidation is finished. After having sufficiently cooled, the cylinder is transferred to the jar containing hydrogen, when again it begins to ignite, throwing off a strong light, while water condenses on the sides of the jar. Since the change of weight, by the alternate process of oxidation and deoxidation, of a cylinder of the above dimensions is nearly one gramme, it may be exhibited in a lecture room by an ordinarily good balance.

Another Experiment to Illustrate Reduction and Oxidation. — A well-polished small copper bell is placed in a ring on a triangle, and then heated by causing a strong gas flame to play upon it, so as to render the metal red-hot, and, consequently, very soon black. As soon as this is the case, a strong current of hydrogen gas is directed upon the metal, by means of a flexible tube fastened to the neck of a glass funnel large enough to cover the bell. As soon as the hydrogen comes into contact with the red-hot metal, the layer of black oxide of copper is removed, and the metal appears as before it was heated. By

removing the current of hydrogen, the oxygen of the air again acts upon the hot metal; and thus the alternate oxidation and reduction may be continued, provided the metal was made thoroughly red-hot to begin with. The hydrogen should be pure, and free even from traces of sulphur or arsenic, in order that the experiment be successful.

HOUSEHOLD RECIPES.

To Take Bruises out of Furniture. — Wet the part with warm water; double a piece of brown paper five or six times, soak it in the warm water, and lay it on the place; apply on that a warm, but not hot flat-iron till the moisture is evaporated. If the bruise be not gone, repeat the process. After two or three applications, the dent or bruise will be raised to the surface. If the bruise be small, merely soak it with warm water, and hold a red-hot iron near the surface, keeping the surface continually wet — the bruise will soon disappear.

Spots on Mahogany. — Stains and spots may be taken out of mahogany with a little aquafortis or oxalic acid and water, rubbing the part by means of cork, till the color is restored, observing afterwards to wash the wood well with water, and to dry and polish as usual.

To Polish Marble, etc. — Marble of any kind, alabaster, any hard stone, or glass may be repolished by rubbing it with a linen cloth dressed with oxide of tin (sold under the name of putty powder). For this purpose a couple or more folds of linen should be fastened tight over a piece of wood, mat or otherwise, according to the form of the stone. To repolish a mantel-piece it should be first perfectly cleaned. This is best done by making a paste of lime, soda, and water, well wetting the marble, and applying the paste. Then let it remain a day or so, keeping it moist during the interval. When this paste has been removed the polishing may begin. The linen and putty powder must be kept constantly wet. Glass, such as jewelers' show-counter cases, which becomes scratched, may be polished in the same way.

To Cook Birds for Convalescents. — Lay them upon the gridiron; broil until they have a light brown color; then put them in a stewpan; pour over hot water enough to cover them. Let them stew until tender. Season with a little fresh butter, pepper, and salt. Chicken, birds, and squirrels, stewed in a double kettle, are very delicate for invalids. If permitted, stuff the fowls and birds with minced oysters.

How to Cook Beets. — Beets should be carefully washed, but not cut before boiling, as cutting them allows the juice to escape, leaving them white and hard. In summer boil them an hour in salted water, and in winter boil them four hours. After boiling, scrape off their skins, and cut off the threads hanging from them.

How to Broil without Burning. — In broiling a beef-steak, whenever the coals blaze up from the drippings, a pinch of fine salt thrown upon them will instantly extinguish the flames. By carefully attending to this matter, you may have your broiled steak or chicken crisp, but not scorched, and juicy, yet well done.

Iron Obtained by Electrolysis. — Professor Jacobi, of St. Petersburg, has ascertained that the iron obtained by electrolysis is not, as has been often thought, the pure metal, but, on the contrary, a compound or mixture of iron and hydrogen, which, when heated to redness, gives off an enormous amount of that gas, and becomes, while greatly increasing in bulk, a silver white, very soft, ductile, and malleable metal, which decomposes water readily below its boiling point, and oxidizes most rapidly.

The Arts.

A NUISANCE MADE USEFUL.

"Commercial nothings" is a term we once saw applied to waste products that cannot be utilized. They are worse than worthless, for in many cases they are produced in enormous quantities, and it costs a good deal to get them out of the way. If they are offensive in their nature, an additional expense may be necessary for deodorizing or disinfecting them. "Gas lime," or lime spoiled in the purification of coal gas, has long been a notable instance of such a product, and it is said that nothing but the expense and trouble of its removal drove the London gas companies to the use of ferric hydrates in its stead. But now this nasty residuum is employed in England in the manufacture of what is known as the "Prideaux cement." This bids fair to become a very important industry. In Sheffield upwards of 700 tons of gas lime have been worked up. The larger part has been applied to walls and floors, hearths and mantel-pieces. Of the latter about 200 have been moulded and sent out. In four of the busiest parts of the town, causeways have been paved by laying the cement with a certain proportion of broken slags from the neighboring furnaces. These have stood the heavy rains very well, and are likely to come into close competition with the asphalte usually employed. The cement is also an excellent material for floors and roofs. Old boarded floors of warehouses have been covered with it about an inch thick; and even in workshops, where polishing machinery keeps everything in vibration, it stands intact. For the roof of a shed the cement was laid on a light frame of wood and troweled to a smooth face, and in the space of twelve hours it was hard enough to bear standing upon.

With regard to the composition of this new cement, the London *Builder* says: —

"It is not a Portland or a Roman cement, although some hydraulic characters are very distinct. It does not set so quickly, but allows more time for finishing up the faces of moulded work. It is far from common mortar; for without any sand it can be formed into blocks which set hard throughout. A piece of a mantel-piece which had been made some six months, gave the following results upon analysis:

Carbonate of lime	69.08
Sulphate of lime (hydrated)	22.63
Hydrate of lime	1.36
Sulphide of calcium	*trace*
Insoluble matter	6.50
Alumina and oxide of iron	.45

"It is obvious, from the above, that the setting must at first be due to the combination of water with the dehydrated sulphate of lime, or, in other words, the plaster of Paris formed by the calcination of the cement. The quantity of caustic lime which is present in the cement keeps the plaster of Paris always fresh, that is, dehydrated, until mixed with excess of water employed at the moment of using it. This will account for the fact that the cement does not lose its quality by keeping, as the hydraulic cements do. After the plaster of Paris is set, the caustic lime goes on absorbing carbonic acid, and thus indurating the mass in the ordinary manner of lime mortars."

Strength of New Zealand Flax. — The strongest vegetable fibre known is the New Zealand flax. It has long, sword-like leaves, ten or twelve feet in length. It is used by the settlers for binding sheaves, fastening gates, and tying up horses.

MEMORANDA IN THE ARTS.

A Starch Factory. — The magnitude of th starch manufacture may be inferred from the exte of a single establishment. The "Oswego Star Works," located at Oswego, N. Y., cover about t acres, and consume 750,000 bushels of corn year in making 8,250 tons of starch, or 16,500,0 pounds, equal to 26 1-2 tons per day. To pack th amount of starch, 250,000 pounds of wrapping-pap are required, and four million feet of lumber f boxes. Over 500 operatives are employed in the e tablishment. The dimensions of the factory buildin are about 615 feet front, partly seven stories hig with 521,000 square feet of flooring, or more th sufficient to cover twelve acres. The factory h about six hundred cisterns or vats, capable of holdi 2,200,000 gallons of water for cleansing the starc from all impurities. There are forty-one forc pumps, capable of raising 523,000 gallons of wat per hour. The length of gutters for distributi the starch is more than three miles. For grindi the corn there are twenty pair of burr-stones, ar six pair of large, heavy iron rollers. There a over three miles of shafting, over twenty miles steam pipes for drying, and twelve turbine wate wheels of 50 horse-power each.

New Signal-light for Railway Trains. — A signal-light, to be attached to the rear car of train, invented by two officers of the Little Mian Railroad, has lately been tested on that road. I the centre of the roof of the rear car of the trai over the rear axle, is placed a square lantern, wit alternate panes of red and white glass. The la tern is connected, by means of a shaft, with one o the axles in such a manner that eight revolution of the axle produce one of the lantern. When th car stops, the lantern, of course, ceases to revolve Upon each side of this main lantern are two others also connected with the axle in such a way tha when the train is moving forward a solid red light is displayed, and, if backing, a solid green light. The engineer of a train coming up in the rear can thus tell, by observing these lights, whether the train before him is moving or at a standstill, and, i moving, in which direction.

Artificial Stone in California. — The *Sci entific Press* describes a visit to the Pacific Stone Company's works, where they are now turning ou daily two tons of stone made by Mr. Ransome's process, and under his own supervision. He has engaged to spend several years in San Fransisco in order to superintend the business. The new church for Rev. Dr. A. L. Stone's society is to be built of stone furnished by this company. A great variety of ornamental work, vases, baptismal fonts, tombstones, etc., are made, and any desired shade of color is given to the material. The stone withstands the effects of heat and cold, moisture and dryness, and other climatic influences. It is a perfect imitation of natural sandstone, and is, in fact, a stone, not plaster, nor concrete. It can be shaped after any design, however intricate, at a comparatively low cost; and the more complicated the design, the less the expense compared with that of natural rock.

The Wear of Wood-cuts. — There seems to be hardly any limit to the number of impressions a wood-cut will yield. The elasticity of wood gives it a great advantage over metal in press printing. Many thousands of impressions may be taken by a moderately careful printer without injuring a wood-cut. To show with what impunity a bad printer may use a coarse wood-cut, may be mentioned the fact that the ballad printers of the middle of the last century occasionally used cuts that had been engraved in the reign of Charles I., and had headed popular ballads for more than a hundred years.

Anaconda Skin Leather. — Prescott tells us that the Aztecs made their war-drums of serpent

skin, but we were not aware until very recently that any of our modern leather had such a snaky origin. An exchange states that a single establishment in Boston, last year, tanned fifty anaconda skins for boot leather. The boots are valued at $50 a pair. The largest of these skins was forty feet in length. The tanning processes were similar to those in the manufacture of alligator leather, the product being a very beautiful and highly finished quality of leather, glossy, mottled, pliable, and exceedingly durable.

CONSUMING SMOKE. — According to the *Iron Age*, a number of experiments made in Ohio show that nothing is so simple and effective in preventing the escape of smoke as the introduction of sufficient oxygen into the furnace to effect complete combustion of the fuel.

COPPER MINING IN CORNWALL. — This business, which has been steadily declining — in 1860, the product was 145,359 tons, but in 1869 it had fallen to 71,790 tons — is now suffering from a new form of competition. Iron pyrites is now imported in enormous quantities from Spain and Norway, for the manufacture of sulphuric acid on the Tyne and in Lancashire. After the extraction of the sulphur from the Spanish ores, the residue is operated on for the 2 per cent. of copper which it contains; and in 1869 no less than 4,000 tons of the metal were thus obtained, the entire yield from native ore being given that year as only 8,291 tons. The importation of pyritic ore increases daily.

ARTIFICIAL INDIA RUBBER. — According to Sonnenschein, if tungstic acid or tungstate of soda be added to glue, and afterwards muriatic acid, a compound of tungstic acid and glue is precipitated which is so elastic at 85–105° F., that it can be drawn out in very thin fibres. On cooling, the mass becomes very solid and brittle; but it may be rendered elastic again by warming. It is proposed to employ this substance in place of the costly albumen as a mordant for cotton, especially for aniline colors. The same material has been used in tanning leather; but this became hard as a stone, and consequently unsuitable for ordinary purposes.

THE OCEAN TELEGRAPH.

HERE is a man sitting in a darkened room at Heart's Content. The ocean cable terminates here. A fine wire attached thereto is made to surround two small cores of soft iron. As the electric wave, produced by a few pieces of copper and zinc at Valentia, passes through the wire, these cores become magnetic enough to attract a light iron bar. A looking-glass, half an inch in diameter, is fixed on a bar of iron one-tenth of an inch square and half an inch long. On this tiny glass a lamp is made to glare so that its light is reflected on a tablet on the wall. The language of the cable is denoted by the shifting of this reflected light from side to side. Letter by letter is thus expressed in this flitting idiom in utter silence on the wall. There is no record made by the machinery except as the patient watcher calls out to a comrade the translated flashes as they come, and which he records. It seems a miracle of patience. Something of awe creeps over us as we see the evidences of a human touch three thousand miles away swaying that line of light.

An English journal gives the following curious statistics concerning the submerged wire that unites the two continents: —

"The Atlantic cable, although it is only about an inch in diameter, covers an area of over a million square feet of the earth's surface, that is to say, about 23 acres of ground at the bottom of the Atlantic Ocean, the area, indeed, of a small farm.

"The inductive surface of the conductor of the Atlantic (1865) cable is about 481,000 square feet, or 11 acres of area. The exterior inductive surface of the gutta-percha is 1,526,845 square feet, or 35 acres.

"The conductor of this cable contains 263 tons of copper, drawn into 13,250 nautical miles of No. 18 wire, a length which, laid over the surface, would more than suffice to join the north and south poles of the earth.

"The insulation contains 338 tons of gutta-percha and compound.

"A No. 16 copper wire, of the same resistance as a mile of the insulator of the (1865) Atlantic cable, would be over 8,000 millions of miles long, that is to say, long enough to be laid round the orbit of the planet Neptune."

PRACTICAL RECIPES.

WASHING FOR ROOFS AND BUILDINGS. — Slake lime in a close box to prevent the escape of steam, and when slaked, pass it through a sieve. To every six quarts of this lime, add one quart of rock salt and one gallon of water. After this boil and skim clean. To every five gallons of this, add, by slow degrees, three quarters of a pound of potash and four quarts of fine sand. Coloring matter may be added if desired. Apply with a paint or whitewash brush.

This wash looks as well as paint, and is almost as durable as slate. It will stop small leaks in a roof prevent the moss from growing over, and render it incombustible from sparks falling on it. When applied to brick work it renders the bricks utterly impervious to rain; it endures as long as paint, and the expense is a mere trifle.

A CEMENT FOR IRON. — Mix sixty parts of pulverized cast-iron turnings with two parts of sal ammoniac and one part of flour of sulphur; and add water until a paste is formed. A cement is thus obtained which grows hot spontaneously, evolving sulphuretted hydrogen, and soon becoming very hard. Of course it must be prepared immediately before using.

TO PREVENT THE CRACKING OF WOODEN FAUCETS, ETC. — Put the articles in melting paraffine, and heat them there at a temperature of 212° F., until bubbles of air cease to escape from the wood. The whole is then allowed to cool to about 120° F., when the wood is taken from the bath and cleaned from the adhering paraffine by rubbing with a dry coarse piece of cloth.

TO BEND MAHOGANY OR WALNUT MOULDING. — Take two pieces of lumber, one to fit the inside, the other the outside of the moulding (the lumber of course cut to the curves required); soak the moulding in boiling water for ten minutes; then put it between the pieces of lumber; then clamp them together, slowly bending the moulding; let it stand for three days; and it will be fit for use.

GOLD LIQUID. — Mix bronze powder with gum water; a little spirits of wine will make it keep better. The proportions are easily ascertained by trial. Pieces of glass may be put in the bottle to assist in shaking up the heavy powder, which settles at the bottom.

TO FASTEN RUBBER TO WOOD AND METAL. — As rubber plates and rings are now-a-days almost exclusively used for making connections between steam and other pipes and apparatus, much difficulty is often experienced in making an air-tight connection. This is obviated entirely by employing a cement which fastens alike well to the rubber and to the metal or wood. Such cement is prepared by a solution of shellac in ammonia. Soak pulverized gum shellac in ten times its weight of strong ammonia, when a slimy mass is obtained, which in three to four weeks will become liquid without the use of hot water. This softens the rubber, and becomes, after volatilization of ammonia, hard and impermeable to gases and fluids.

Agriculture.

A MINERAL FERTILIZER.

THE Nashua (N. H.) *Telegraph* of March 4th contained a letter from Levi Bartlett, Esq., of Warner, in which he speaks in commendation of what is known as the "Grafton Fertilizer." There are few more sensible, intelligent farmers, or careful observers, in New England, than Mr. Bartlett, and his views are always entitled to respectful consideration. The fertilizer alluded to by Mr. B. has been made the subject of comment in the JOURNAL, and from the analysis presented we learned that the powder could have but little value, and this fact was clearly stated. It probably has *some* value, but how much? It contains *thirty per cent.* of *sand*, six of iron, and sixty-three of magnesian and common limestone. The sand and iron can be of but little account, as both are plenty enough for all practical purposes in nearly all soils. The common lime rock is not worth as much for agricultural purposes as commercial lime, as it is in the form of a *carbonate*, and the carbonate of lime is the hard, insoluble, and worthless powder found in the yards of marble cutters. The magnesian carbonate is the most valuable ingredient, but this is in an insoluble condition, locked up in association with the lime. It is cheaper and better to procure the magnesian element needed in our soils, by the use of the soluble sulphate which can be bought for less than two cents the pound. Now, what is this rock powder worth, which contains but about fourteen hundred pounds in the ton of substances which can have any agricultural value? Is it worth the price asked for it, $30 the ton? Is it worth half or a quarter part of that sum? Is our friend Mr. B. willing to recommend this powder to his brother farmers at anything like these prices? We think not. A *carbonate* of lime must not be confounded with the *sulphate* of lime, which is *gypsum*. Gypsum gives rise to an entirely different class of reactions when placed in the soil. Sulphuric acid and carbonic acid, agriculturally considered, have far different values. Carbonic acid *has no value*, as the air and the earth supply it to plants in abundance.

We must not allow ourselves to be perplexed or deceived in these matters. We are not yet quite ready to burn our books upon scientific agriculture, and throw ourselves into the arms of advertising fertilizer makers who offer no other guarantees than the cheap certificates of those who are too willing to sign them.

CORN AND WHEAT CROPS AT LAKESIDE.

[*From Dr. Nichols's Address.*]

A CROP of corn has been raised each season since 1864, and also a crop of spring wheat until the present year. Rye, oats, roots, and potatoes, with the various grasses, complete the list. From careful records of expenses and results I find the corn crop to have been the most remunerative, and the wheat comes next. During the seven consecutive seasons, closing in 1870, we have passed through great vicissitudes of meteorological changes. We have had seasons characterized by extreme wet, and unparalleled heat and drought; some have been quite extended, and others have been very brief. That of 1869 gave us only about one hundred days in which to plant and harvest our corn; the past has been of extraordinary length, the warm, growing weather lasting from early in April to November.

It has been a period of great value to those who wish to gain by experiment and observation a knowledge of the best methods of farming under the extremes of heat and cold, wet and dry, and of the crops best suited to our capricious climate. The farmer who, by imperfect tillage and lazy habits, has reached the conclusion that we in New England have no certain crops, is indulging in grievous error. All our cereal and grass crops are certain enough, if our fields are in perfect condition, but corn may be said never to fail if a reasonable amount of attention is given it. My crop has never fallen below seventy bushels of shelled corn to the acre, and in 1869 I grew, in about one hundred days, a crop of 106 bushels to the acre. So late was this season, that I was able to walk across the ice-bound lake upon which my fields border on the 10th of April, and snow rested on my potato patch the 2d day of May. Corn among crops with us in Massachusetts is like a Bronsonian democrat; it "rises superior to its accidents." The crop at Lakeside the present season, hot and parched as it has been, has reached seventy-five bushels to the acre. The cost of the corn in the aggregate raised during the seven seasons does not exceed 45 cents per bushel. In this estimate we include one half the cost of the fertilizers, and all the labor from the time of planting to shelling, but it does not take into account the fodder which has proved in my experience to have a high value. This has been fed to milch cows in association with wheat straw, in the long and cut condition, and careful observation and experiment show that it is worth nearly as much, as a milk-producing agent, as upland hay. Corn, gentlemen, is the cereal to which we should give special attention. To grow it profitably, we must grow large quantities on small parcels of ground. It requires no greater expense for labor to raise seventy-five or one hundred bushels to the acre, than to raise twenty-five. Corn can be grown in good quantity for several consecutive years upon the same field, by the use of agents which hold those great essentials to plant growth, phosphoric acid, potash, and lime; but to attain to the highest success, substances capable of affording the nitrogenous element must be added. The first three years of my experiments with the corn crop, I depended solely upon dressings composed of lime, potash, or ashes, and flour of bone, and my crops were excellent; but I now use in association four cords of good, fresh farm dung to the acre, spread over the ploughed field, and harrowed in with a Geddes harrow. Into the hills at the time of planting, I place a handful of a mixture of fine bone and ashes, and under this treatment I have learned to anticipate heavy crops with full confidence. For corn, or indeed for any crop, I prefer to plough in the autumn. One of the most important items to be taken into account in the cultivation of the soil is the fineness of the mould in which the seed is placed. A hard, lumpy, imperfectly pulverized field, holding equal amounts of the elements of plant nutrition with one that is fine will fall short usually twenty per cent. in product under the same meteorological conditions. In autumn ploughing we secure the disintegrating influence of frost upon our furrows, and this is a costless aid in soil cultivation. There are other advantages which I will not stop to enumerate.

For five consecutive years I have not failed, under what I regard as proper soil treatment, to secure good crops of wheat. In one season, that of 1869, it fell to twenty-one bushels to the acre, but the others have not gone below thirty. It was indeed singular to find what a strong prejudice existed among farmers against attempts to raise this noble grain. It was urged that it could not be grown on our soils, — they were worn out, — did not hold lime or something else necessary to its development, — and further, if it did g ow, rust, mildew, or insects would destroy the crop before maturity. The first year, I startled a neighbor by growing a crop of plump wheat, thirty-one bushels to the acre, while over the fence he grew a crop of barley fifteen bushels to the acre. I sold my wheat at $3.50, while his barley went for $1.40 per bushel. The plan of soil treatment has been to sow broadcast, early in the spring, 500 lbs. of farm superphosphate to the acre, mixed with 100 lbs. of crude nitrate of potassa, or 150 lbs. of nitrate of soda and 59 lbs. of sulphate of magnesia. The importance of magnesia in the ash of wheat has been strangely overlooked by chemists and by experimenters, and I regard the employment of a salt holding this element in dressings for wheat land as of great utility. Nearly one eighth of the ash of wheat is made up of magnesia, and as our granitic New England soils cannot well supply it, we must furnish it in our manures. As regards the evil influence of rust upon wheat, I am inclined to the opinion that a well-fed, vigorous plant possesses a power of resistance to parasitic growths which is, in a considerable degree, protective. I do not mean to say that the farmer can positively and always place himself beyond the reach of disasters resulting from fungoid plants or destructive weather influences, but I do say that a good, vigorous well-fed stalk of wheat, corn, or other grain will bear up under and resist adverse influences better than one that is half starved and weakly. The battle is in favor of the strong and against the weak, among plants as well as among men and animals.

WHAT SOUTHERN FARMERS NEED.

At a late meeting of the Vicksburg Chamber of Commerce, W. J. Sykes, Esq., of Memphis, Tenn., spoke upon the matter of the development of Southern resources, and in the course of his remarks used the following language: —

"I will tell you what we Southern people need; we want Yankee enterprise. Do you know the commercial difference between a Northern and Southern man? The Southern man sells all he can't eat, and the Northern man eats all he can't sell. He gets our money, and then we go to him to borrow. He gets our three hundred millions, and then loans us the money. Did you ever see a Southern planter who didn't want to borrow money? The more cotton he makes, the more money he must borrow. The cotton mania is our curse."

The *Banner of the South* (Augusta, Ga.), one of the ablest agricultural journals of that section, after quoting the above, proceeds as follows: —

"The only remedy for our misfortunes has been over and often urged — diversity of crops: cease concentrating everything on cotton, raise provisions enough at home to be independent of merchants and bank rates of interest. But to urge such a course seems to have a contrary effect, for every individual thinks his neighbors will all follow the suggestion, and that he himself will do better by planting all in cotton, as before. And so again everything we produce is cotton.

"While the credit system obtains, and men may spend crops before they are made, this will likely be the case. If credit were withdrawn, then the matter would be brought home to every man on every farm. Let it be fully known that next year there shall be positively *no credit* for corn and meat, and each one would then feel himself forced to look to his own resources for supply. Both the planter and the merchant would be soon on a safer footing than now prevails."

They are beginning to raise Cashmere goats in California. It is said that it costs no more to raise a goat than a chicken.

SEEDS AND CUTTINGS.

Salt Water for Strawberries. — The Norfolk *Virginian* is informed by a practical horticulturist that during an overflow from an extraordinary storm a strawberry bed was partially covered with brackish water at the time when fruit was forming, and also that the occurrence stimulated the vines to greater perfection of fruit and general vigor. This discovery may prove of advantage to fruit raisers in the vicinity of salt water.

Tender Lettuce and a Tough Story. — It is said, in *Harper's Magazine*, that lettuce may be produced in winter, in from twenty-four to forty-eight hours, by taking a box filled with rich earth in which one-third part of slaked lime has been mixed, and watering with lukewarm water. Sow the seed in the usual way, after they have been previously soaked in brandy for twenty-four hours.

Melon Sugar. — In Italy and Hungary there are several large manufactories of *melon sugar*, and it is believed that the culture of melons for this purpose could be made profitable in this country. The proportion of saccharine material in the juice is about seven per cent., while in beets it is only one per cent. more, and the cost of expressing the juice is much greater than from the melons.

The editor of the *Rural Carolinian* says that he once made a very fine article of syrup from melon juice, but did not carry the experiment further.

Changing the Colors of Flowers. — An English paper describes a case of a yellow primrose which, when planted in a rich soil, had the flowers changed to a brilliant purple. It also says that charcoal adds great brilliancy to the colors of dahlias, roses, and petunias; carbonate of soda reddens pink hyacinths, and phosphate of soda changes the colors of many plants.

Southern Phosphate Manufacture. — The Charleston (S. C.) *News* says: "We have now twelve phosphate mining and manufacturing companies, representing a capital of *three millions of dollars*. Eight of these companies are now mining and manipulating phosphates; a fleet of vessels carry the crude rock abroad and to the North; long trains of cars bear the quickening fertilizer to all the States of the South. And the basis of all this business — the phosphatic deposit — lies in inexhaustible quantities in the broad bosom of South Carolina. Several of the companies manufacture the acid required for their work."

Fun and Farming. — The editor of the Trenton (N. J.) *Sentinel* is telling what *he* "knows about farming," *à la* Greeley. The following is a part of his first essay on the subject: —

Castor-oil beans succeed best in the bowels of the earth. They will soon work their way out.

The best preparation for hops is a toad or two in each hill. They will make the vines fairly jump.

The usual time to put in rye is early in the morning. Some husbandmen, especially those of the city, continue to run it in at intervals of half an hour, until bed-time. The practice is only allowable in case of a dry season.

In reaping wheat, never take it by the beard. It is found to go against the grain.

Corn in the ear is apt to affect the hearing. If eaten green, it will make the voice husky. When dealt out as army rations, the kernel should always be served first, and then the men, private-ly.

Never plant your potatoes early. It is the early potato that gets the worm. It is up-hill work with them after that.

In making cider out of apples, I found it a pretty tight squeeze, nowithstanding my long connection with the press. Never drink cider made from crab apples. It is pretty certain to go "back on you." If you would lay in a supply of old wine, be sure to make it of elder-berries.

IRON FOR PEAR TREES. — A correspondent of the *Rural Messenger* writes as follows: "I had a very fine pear tree (Flemish Beauty) that became affected, first by blight in one limb, which I removed, and then another and another was affected in the same way, until I had removed a considerable portion of the top of the tree. Early next spring I resolved to try the application of scrap iron to the roots. I procured my iron, removed the soil from the roots carefully, deposited the iron between them, and replaced the earth. There was no further progress in the blight, the tree continued to grow that season, and the next leaves and blossoms came out vigorously; no black spots appeared on the leaves, and the tree bore finely; and no appearance of disease was seen in the tree afterward. In subsequent conversations with friends I found that some of them had become informed on the same subject, and had tried the remedy with perfect success. Some told me they had procured turning and drilling chips from the machine-shops, and had used them, as they thought, with much advantage to their trees."

TO GET RID OF ANTS IN GARDENS. — Entrap them by means of narrow sheets of stiff paper, or strips of board, covered with some sweet sticky substance. They will thus be attracted and get stuck fast, and when you have caught a goodly number you can kill them, and set your trap again.

Or lay fresh bones around their haunts. They will leave everything else to attack these, and when the bones are well covered with them, you can dip them in boiling water, or otherwise "murder the innocents."

If you wish merely to drive them away (with the prospect of having them settle elsewhere within your borders) a few spoonfuls of coal oil poured into their holes, or a few slices of raw onion buried there, will be taken by them as a *strong* hint to migrate.

VICK'S ILLUSTRATED CATALOGUE. — We have received a copy of this catalogue, advertised in a former number of the JOURNAL. It is a handsome pamphlet of 96 pages, with two colored plates and numerous wood-cut illustrations. The 150,000 copies circulated annually are printed at Mr. Vick's own establishment in Rochester, N. Y., where he also makes the million paper boxes he uses each year. Although he has seventy-five acres devoted to the raising of his seeds, he purchases large quantities of other producers, besides importing foreign seeds and plants to a large extent. He has a large building, four stories high, in which he employs 106 hands, including 76 girls. This enormous business has grown up from a very humble beginning, and is so admirably managed that it is likely to keep on growing.

THE London *Cottage Gardener* relates an experiment which shows the advantage of keeping the leaves of plants free from dust. Two orange trees, weighing respectively eighteen and twenty ounces, were allowed to vegetate without having their leaves cleaned, for a year; and two others, weighing respectively nineteen and twenty and a half ounces, had their leaves sponged with tepid water once a week. The first two increased in weight less than half an ounce each, while of the two latter, one had increased two, and the other nearly three ounces.

THE toad is a great destroyer of insects, and has been found very useful in gardens for exterminating the striped bug, squash bug, flea-beetle, etc. It devours the potato bug with great avidity, and suffers no inconvenience from feeding on this poisonous insect.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, MAY 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

TO ADVERTISERS.

Advertisers are hereby informed that the Boston Journal of Chemistry circulates more copies monthly than any other periodical of its class in this country. It goes into every State and Territory of the United States, and to the British Provinces, England, Scotland, Germany, Australia, etc. It is the best medium for advertising drugs, medicines, chemical substances, chemical and philosophical apparatus, telescopes, microscopes, educational institutions, lectures, books, musical instruments, articles of food, furniture, agricultural implements, seeds, fertilizers, wines, soda-water apparatus, surgical instruments, the business of physicians and druggists, etc., etc., that the country affords.

A SECOND "REPORT" FROM DR. WINSOR.

THE second report on galvanized iron pipes by Dr. F. Winsor, so long anticipated, has appeared in one of the April numbers of the *Boston Medical and Surgical Journal.* The Doctor has made "further inquiries of *skilled analytical chemists*, of experts in materia medica, of *manufacturers of galvanized iron pipes, house painters*, etc.," and is satisfied that the pipes are "all right," and that his views as first expressed are correct. It is gratifying to find that he has extended his field of inquiry; his former one was entirely too narrow, — "Appleton's Cyclopædia, and the pipe makers." The only "skilled analytical chemist" he has consulted is the writer of the following remarkable certificate, recommending some "Bitters" which have recently appeared in the market: —

"20 STATE STREET, BOSTON.

"J. A. BRODHEAD, ESQ., *State Commiss., Mass.*

"Sir, — A sample of 'Old Dr. Warren's Root and Herb or Quaker Bitters,' from Flint & Co., Providence, R. I., has been analyzed with the following results: This is not a beverage nor an intoxicating liquor, but is an official medicinal preparation containing extracts of roots and herbs.

"It is free from injurious substances, and may be used as directed by persons requiring a medicine of this kind. Very respectfully,

"S. DANA HAYES,
"*State Assayer and Chemist.*"

He informs us that this State Assayer has made "more than one hundred analyses of water drawn through galvanized iron pipes," every one of which confirmed his notions of their safety. The wonder is that the gentleman could find time to make such extensive researches on the galvanized iron pipes, as he has to make about *thirty thousand analyses* yearly of liquors at the State Agency, and this labor, added to the assays of bitters, pills, teething rings, rubber nipples, etc. etc., certificates regarding which are constantly appearing in the newspapers, must keep him pretty busy.

There is a bit of clever irony manifested by the editor of the *Medical and Surgical Journal* in placing the "Bitters" certificate and the Report of Dr. Winsor in close contiguity in his columns. We hardly know which document to admire most, or which is entitled to the highest confidence. They both come from distinguished sources; one recommends "Old Dr. Warren's Root and Herb Bitters," the other the galvanized iron pipes. Both parties seem to be involved together in important researches, although we do not suppose the Doctor has anything to do with the Bitters of the Assayer. Seriously, we dislike that the ten thousand intelligent physicians and chemists of the country who read our JOURNAL should know that such documents are published in Massachusetts by parties who ought to be far removed from charlatanry in any form. But the facts are of such a nature as to demand notice.

It should be remarked that Dr. Winsor in a very contemptuous way dismisses the cases of poisoning by zinc reported in the JOURNAL as unworthy of *his* notice, and he also ignores the reports of zinc poisoning in England and elsewhere. We regret that he has placed himself in such a position.

THE LESSONS OF THE ECLIPSE.

OUR readers have seen ere this, in the papers of the day, the accounts of the good and bad fortune that attended the various expeditions sent out to watch the great eclipse of December 22d. The scientific results have not been so important as it was hoped they might be, but they are far from insignificant, and are amply worth all they have cost. Mr. Lockyer considers that the chief gain is the additional evidence of the compound nature of the corona, which must be viewed as partly a true solar appendage, and partly due to our own atmosphere. The following is the conclusion (somewhat condensed) of his article on the subject in *Nature*: —

"From what has preceded, then, we seem justified in suggesting as working hypotheses the following, which, however, more accurate information may alter, and which I offer as suggestions only, *bien entendu.* 1. The solar chromosphere extends some 5′ or 6′ from the sun, its last layers consisting of cool hydrogen, and possibly a new element with a green line in its spectrum; which line, if it be identical with the auroral line as stated by Gould, may possibly be present in the higher regions of our own atmosphere. 2. Outside this stratum the rays, etc., are, for the most part, due partly to our own atmosphere, partly to our eyes, for their shape varies; they are seen by some at rest, by others in motion, and their spectrum is the same as that of the dark moon. 3. The white light of the chromosphere above the prominences, as seen in an eclipse, is due to its strong reflection of solar light, as shown by the polariscopic observations. 4. The rosy tinge of the corona proper, that is of the region more than 5′ or 6′ from the sun, is due to our atmosphere containing light which comes from the higher and lower strata of the chromosphere."

One of the most interesting results of the observations is the confirmation of the American observations of 1869. The *Cornhill Magazine* has given a very clear statement of the results obtained previous to 1869, the discoveries made in this country in 1869, and the way in which these were viewed by English astronomers before and after the eclipse of 1870. We quote a portion of the article: —

"In 1868 Tennant had found that the spectrum of the corona is a continuous rainbow-tinted streak, without either dark lines or bright. Such a spectrum is given by solid and liquid bodies glowing with intensity of heat. And the inference, therefore, was that the corona consists of minute bodies travelling close by the sun, and owing the greater part of their light to the great heat with which they are transfused. But the American observers in 1869, or at least some of them, found that besides the ribbon of rainbow-tinted light, the spectrum of the corona shows bright lines. Some observers saw only one bright line, others saw three. This observation would indicate that a portion of the coronal light comes from a gaseous source, and from the position of one of the bright lines Professor Harkness was led to the strange conclusion that the glowing vapor of *iron* is a constituent of the solar corona! Yet further, because the position of these coronal lines corresponded with the position of the bright lines seen in the spectrum of the aurora, Professor Young, one of the most skillful of the American spectroscopists, came to the conclusion that the corona is a *perpetual solar aurora!*

"The observations of the American astronomers and physicists were not accepted by all. No valid reasons were given, indeed, for rejecting them, but they are pronounced, in general terms, to be '*bizarre* and perplexing in the extreme.' Possibly, too, some of our English physicists had not formed a duly high opinion of the skill of their American fellow-workers. But, be this as it may, certainly the American astronomers were somewhat cavalierly treated, and the acceptance of their observations was postponed until such time as European astronomers should have been able to confirm those perplexing results.

"The chief interest of the eclipse of last December undoubtedly attaches to this special question. . . . . The question whether the American observations would be confirmed or not, was one on which grave doubts prevailed in many quarters. For ourselves, we must admit that these doubts had seemed to us to involve an unjust disparagement of the skill of American men of science, who have again and again proved themselves the equals of the best European observers in judgment and acumen, and often their superiors in energy. A careful study of the accounts given by the heads of the different observing parties had convinced us that future observations would confirm the statements made by the spectroscopic observers of the American eclipse.

"This has in effect happened. The first fruits of the eclipse expeditions of 1870 may be said to consist in this important fact — that the observations made in 1869, *bizarre* and perplexing though they seemed, have been shown to be exact and trustworthy."

After discussing at considerable length the significance of these results, the writer comes to the conclusion (which, on the whole, appears to us the most satisfactory one to be reached in the present state of our knowledge) that Prof. Young's theory that "the corona is a perpetual solar aurora" is likely to be the correct explanation of the matter; and that the corona, the zodiacal light, and the terrestrial aurora are probably to be viewed as related phenomena. "When we remember that the zodiacal light — a phenomenon which holds a position midway between the terrestrial aurora and the solar corona — has been shown to give a spectrum closely resembling both the auroral and the coronal spectra, the idea does seem certainly encouraged that all three phenomena are intimately associated."

DARWIN AND HIS DOCTRINES.

One of our leading American critics, in an elaborate review of Mr. Darwin's last book, has the following remarks: —

"Whatever judgment may be pronounced as to the tendency of Mr. Darwin's views of the origin of man to humble the natural pride of ancestry, we ought not to lose sight of the fact that no philosophical writer of the present day sets forth a more exalted conception of the actual faculties and endowments of the race as developed under the highest forms of moral and religious culture in the progress of civilization. He almost goes out of his way to do justice to the ideas and beliefs which have been regarded by the wisest thinkers in every age as the crowning glory of humanity. In this respect his system presents a favorable contrast to the shallow, sensualistic, French philosophy of the eighteenth century, which resolves the most refined sentiments of our nature into fleshly illusions. 'The question,' says Mr. Darwin, 'whether there exists a Creator and Ruler of the Universe has been answered in the affirmative by the highest intellects that have ever lived. I fully subscribe to the judgment of those writers who maintain that of all the differences between man and the lower animals, the moral sense or conscience is by far the most important. This sense, as Mackintosh remarks, "has a rightful supremacy over every other principle of human action;" it is summed up in that short but imperious word *ought*, so full of high significance. It is the most noble of all the attributes of man, leading him, without a moment's hesitation, to risk his life for that of a fellow-creature; or after due deliberation, impelled simply by the deep feeling of right or duty, to sacrifice it in some great cause.'"

Another critic speaks as follows: —

"We cannot but pay a just regard to the fact that Mr. Darwin, while advancing views that are often startling, never uses an expression likely to cast a doubt upon the divine attributes of man, or to lower the respect for the Christian religion. He is an iconoclast who breaks only the idols of false gods."

The most effective reply to Darwin that has yet appeared is "The Genesis of Species," the book just put forth by Mr. St. George Mivart. The author fully appreciates Darwin's merits as a scientific man, and admits the plausibility of the doctrine of "natural selection," which he himself was disposed to adopt until careful examination convinced him that it was inadequate to explain all the facts involved. He then proceeds to show wherein the theory fails, and the objections he brings forward seem to us unanswerable. We shall be curious to see how Darwin replies to them. Mivart does not deny that natural selection acts to some extent in the organic world, but he maintains that if we would account for the production of existing species of animals and plants, it must be supplemented by the action of some other natural law or laws as yet undiscovered. His aim, as stated by himself in the closing sentence of the book, "has been to support the doctrine that species have been evolved by ordinary *natural laws* (for the most part unknown) controlled by the *subordinate* action of 'natural selection,' and at the same time to remind some that there is and can be absolutely nothing in physical science which forbids them to regard those natural laws as acting with the Divine concurrence and in obedience to a creative fiat originally imposed on the primeval Cosmos 'in the beginning,' by its Creator, its Upholder, and its Lord."

EDITORIAL NOTES.

A Chip of the Old Block. — A "Petrified Indian Boy" has lately been on exhibition in Boston. The history of this fossil youth (except that he was "found near Turner's Falls, Mass.") is not given in the handbills, but we happen to know some interesting particulars concerning him and his family, gleaned from a copy of the *Paleontological Times* of April 1st, 49,387 B. C., dug up not long ago in the Onondaga Valley. The boy was the youngest son of the well-known Cardiff Giant. He ran away from the paternal mansion, and wandered eastward as far as Turner's Falls, where he "curled up and died" in the posture in which he now appears. Old Cardiff for many years stood high in the estimation of his fellow-citizens; he was, in fact, looked up to as one of the "solid men" of that section. But later in life he fell into bad ways, became a hard drinker, and abused his wife and children. This was doubtless the reason why the interesting youth mentioned above ran away from home. Mrs. Cardiff herself finally left the hardened old reprobate, and went to Indiana, where she got a divorce, and subsequently married a gentleman named Smith. Nothing further is known of her, nor have we any information of the seventeen other Cardiff children, the brothers and sisters of our petrified juvenile; but the reappearance of the old gentleman on the stage has proved so profitable to his friends of this generation, that they have hunted up this boy, and we doubt not that the rest of the family will yet be found and "carted round as a show." When they get to Springfield, we trust they will be "sot on" by the local scientific association which pronounced the paternal giant to be a "genuine antique," and have their genealogy duly authenticated by that sapient conclave.

American Greek Architecture. — Under the head of "American Wonders," one of our exchanges, after boasting of Niagara, the Mammoth Cave, Lake Superior, the Natural Bridge, and other things in which the Yankee nation "can't be beat," proceeds to say that "the best specimen of Grecian architecture in the world is the Girard College for Orphans, Philadelphia." It is very true that the edifice in question is a notable instance of an immense expenditure of money to produce a structure wholly unsuited to its purpose. Nowhere else in the world probably can one find so much white marble put together so unwisely. But aside from its being one of the most unfortunate examples of the misapplication of Grecian architecture which was the fashion forty or fifty years ago, it is a miserably incomplete reproduction of the old Greek temple. Compared with the Madeleine at Paris, and other modern "specimens of Grecian architecture" in Europe, it is like a frame without the picture it ought to enclose. It is as bare of ornamental sculpture as a country meeting-house; while in the Parthenon and the Madeleine, as in all genuine Greek work of the kind, architecture and sculpture seem to compete with each other for our admiration, or rather they combine to form a harmonious whole, to whose perfection each is essential.

"Pigeon English" on the Wires. — In California, the Chinese residents make a liberal use of the telegraph, and though they do not trouble themselves with an investigation of its workings, they fully appreciate its importance. John, in California, is at liberty to send his messages in "pigeon English," and very funny work he makes of it occasionally. Chin Lung, in Sacramento, telegraphs to Ming Yup, in San Francisco, "You me send one piecee me trunk," which means, in plain language, "Send me my trunk." Mr. Yup complies with the request, and responds by telegraph, "Me you trunkee you sendee."

At Table. — The custom of frog-eating in France seems to date from the end of the fifteenth

century. Champier, writing in 1504, complains of the strange taste of people who eat frogs, and cannot conceive how persons of delicacy can eat "insects" bred in marshes and stagnant ponds. "I have seen the time in which people ate only frogs' thighs, but now they actually eat the whole body, except the head, and, moreover, serve them fried with a little parsley." Yet that the practice was not universal we gather from Palissy, who, in his "Treatise on Stones," says, "It is a thing that one sees every day now, that men eat articles which formerly no one would have eaten for anything in the world. In my time I have known when you could have found very few men who could have eaten either tortoises or frogs." The custom, like that of eating beavers, and that great delicacy, their big, flat tails, probably took its rise in the desire of the fasting or non-flesh-eating monks to get something as like flesh as possible; and they therefore always reckoned amphibious animals as fish, not flesh. In like manner, though certain monks would not eat pork, they flavored their vegetables with lard, and many monasteries kept pigs for this purpose. Other monasteries got so far as to eat hashed meat, saying that when meat was so disguised, it was no longer meat. Gregory the Ninth condemned this artifice in the Constitution he gave to the Benedictines, and declared that not only was meat forbidden to them, but also hashes and stuffing made of meat.

ATOMS.

Out of ninety million passengers conveyed on French railways in 1869 only two were killed, and of the persons employed on the roads only four score; 112 passengers and 61 employees were injured. — In response to a correspondent who wants a recipe for "fluid extract of lemon," the *Druggists' Circular* suggests that "to take ten lemons and squeeze out the juice with a good 'lemon-squeezer' would prove the readiest way to get a pure fluid extract." — As evidences of the "progress of civilization" in China, it is stated that beer is made at Shanghae, and a whiskey distillery is building at Canton. — It is said that the average yearly consumption of coffee for each Californian is sixteen and three fifths pounds, while the average for the whole country is only seven pounds. — Up on the borders of Lake Superior they boast of 350 bushels of potatoes to the acre. — The production of chewing tobacco in Richmond, last year, was more than fifteen million pounds, and of smoking tobacco over one million pounds; and the tax paid on both amounted to more than five millions of dollars. — The *Book Worm* is a new monthly, intended to be of interest to every one who loves books, and to every one else," published at the College Bookstore, New Haven, Conn., for one dollar a year; and the first number is a capital one. — The consumption of oysters in this country is enormous, as may be inferred from the fact that in Chesapeake Bay alone there are three thousand acres of oyster beds, yielding annually twenty-five million bushels of the bivalves. — It is said that nearly every South American seaport has a horse railroad. — Bismuth has been discovered in Texas. — Some of the French cannon captured by the Prussians were made of brass cylinders from the calico print-works of Alsace. — A locomotive factory in Philadelphia employs 1,900 men, and turns out a locomotive daily. — The narrow-guage railway is attracting much attention at the West and South, and also in California. — A new hammer in the Bessemer steel works at Harrisburg, Pa., weighs thirty-five thousand pounds. — Two hundred woolen factories have been started in the Western States in the last ten years. — The cotton crop of 1870 is estimated at 3,000,000 bales. — The manufacturers of cheap confectionery out West will be gratified to learn that a deposit of kaolin has been discovered near Omaha. — A thousand millions of pounds of sugar are required annually to satisfy the "sweet tooth" of the Yankee nation. — The State of New York has now twelve hundred cheese factories, and the business is rapidly extending. — Dolomite is coming into use as a substitute for lime in the calcium light, as it can be used for hours without showing anything more than a slight wear on the sides exposed to the flame. — Darwin's "Descent of Man" will be the "sensation" of the season in scientific literature. — Aluminium does not at present seem likely to become the familiar household metal that writers ten years ago predicted it would. — That charming "juvenile" of the last holiday season, "The Children's Week," is from the same pen that has given us the full and elaborate work on "American Mines and Mining," to which we referred in the last number of our paper. — The *Scientific Press* mentions a California device for economizing coal, by lining the front and bottom of the grate with a wire screen (of No. 16 wire, with half-inch meshes), so that the small pieces of coal which usually drop through the grate are consumed. — An iron canal-boat was built in England as early as 1787. — The *Rhode Island Schoolmaster* is the best of all the State educational journals, and ought to issue a "national edition." — In London there is a steam-engine still running which was built by Boulton and Watt in 1811, and has been in regular use ever since, except when the works were interrupted for a time on account of a fire. — In South America a railroad is planned to connect the Argentine Republic with Chili, a distance of a thousand miles; and the estimated cost is thirty millions of dollars. — Many tons of laurel roots are used in making *briar*-root tobacco pipes.

The Literary World. — We have already commended this excellent monthly, and we cordially endorse what is said of it by the N. Y. *Evening Post* and the Springfield *Republican*, as quoted in the advertisement in this number. Even at the increased price, it will be the cheapest literary journal in the country.

The Food Journal. — By special arrangement with the publishers, we are now able to offer this unique and valuable magazine on even lower terms than previously announced in our *Clubbing List*. We can furnish it, mailed *post-paid* from London, at $2.25 a year, or $3.00 *with the* Journal. We are unable at present to send specimen numbers of this and other foreign journals on our list.

☞ We would call special attention to our advertisement of the *Title-page and Index* to Vol. V. Our arrangements are such that we can send it with our June number far more conveniently than at any other time, and we therefore offer it free to all who renew their subscriptions before June 1. The *ten cents* charged for it after that date will not more than repay us for the extra trouble of sending it.

After some delay on the part of the printer, Dr. Nichols's *Address on Manures* is now ready, and will be mailed at once to all who are entitled to it. If any who ought to receive it fail to get it, they will please inform us of the fact. The pamphlet will be sent, post-paid, to any address on receipt of *twenty cents*. As the edition is limited, early application will be necessary to secure copies.

The "Answers to Correspondents," as well as several articles in type, are unavoidably laid over to the next month.

LITERARY NOTES.

Messrs. Hurd and Houghton have just added to their uniform edition of Hans Andersen's Works *The Story of My Life*, the delightful autobiography of the author, now first translated into English in its enlarged and revised form. The opening sentence of the book is a perfect description of it: "My life is a lovely story, happy and full of incident." And the "moral" follows in the same paragraph: "The history of my life will say to the world what it says to me, — There is a loving God, who directs all things for the best."

The same house has published *Hesperia*, by Cora L. V. Tappan, which appears to be an attempt to put the history of the United States into the form of an allegorical poem; and *Three Successful Girls*, by Julia Crouch, a novel of American life, better than most of its class. It introduces its trio of heroines at the wash-tub, which is a novelty in a novel, but those who believe in the old-fashioned domestic education of girls will consider it the key to their "successful" career.

A popular history of the art of printing ought to have been written long ago, and it was a "happy thought" of Mrs. E. C. Pearson's to furnish us one in so pleasing a form as that of *Gutenberg, and the Art of Printing*. It reads almost like a romance, while it keeps closely to the historical facts. A sketch of the modern improvements in printing is added, to bring the narrative down to our own day; and the book itself is an admirable specimen of the typographic art. It is printed at Riverside, and published by Messrs. Noyes, Holmes, & Co., of Boston.

A new volume in Messrs. Barnes & Co.'s "Teacher's Library" is Mr. H. Barnard's *Oral Training*, or "Lessons in Natural Science and General Knowledge, embracing the subjects of Astronomy, Anatomy, Physiology, Chemistry, Mathematical Geography, Natural Philosophy, the Arts, History, Development of Words, etc."

The Harpers, who are bound to furnish the latest and best dictionaries and works of reference, even if these supersede others already on their list, have reprinted Smith's *English-Latin Dictionary*, which is a great improvement on Riddle's, hitherto the standard in our classical schools. It is more copious than that work, and is especially superior in its full citation of authorities. It represents the most advanced scholarship of the times, and it will probably be many years before a better work will displace it, as it displaces its best predecessor.

The University Publishing Company (New York) are issuing a full series of educational works, with especial reference to the wants of Southern schools. They have now ready a complete set of *Readers*, edited by Prof. Holmes of the University of Virginia, a *History of the United States* (in which, by the way, we see scarcely a line to which any Northern man could object), by the same author, and a *Manual of Geography* by Prof. Maury. All the books, in illustrations, typography, paper, etc., are up to the highest standard, and well deserve the attention of teachers.

Dr. Jas. E. Reeves sends us the second edition of his *Health and Wealth of the City of Wheeling*. In its enlarged form it has increased claims to be called a model sanitary report. The health officers of our cities and towns, and all others interested in sanitary science, will find it very suggestive.

We are indebted to Geo. W. Bull, Esq., Editor of the Buffalo *Commercial Advertiser* for the *Transactions of the New York State Eclectic Medical Society*, for 1869–70, the *Report of the State Commissioners of Public Charities*, and other valuable documents of the New York legislature.

Dr. J. H. Rauch, of Chicago, sends us the *Report of the Board of Health* of that city, for 1867, 1868, and 1869, which includes a Sanitary History of Chicago from 1833 to 1870 — a work replete with interest for every student of social science.

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

The *New York Medical Journal* for April has the following original communications: I. E. R. Squibb, M. D. — Anæsthetics; II. A. Kessler, M. D. — On the Education of Deaf-Mutes; III. O. W. Holmes, M. D. — Valedictory Address, delivered to the Graduating Class of the Bellevue Hospital College, March 2, 1871; IV. Wm. C. Roberts, M. D. — On the Influences of Non-specific Emanations on the Public Health: Are they deleterious?

The *Journal of Psychological Medicine* has the following original papers: The Relation between Lesion of the Nervous System and Muscular Atrophy, by S. G. Webber, M. D.; On the Medical Relations of Insanity, by L. A. Tourtellot, M. D.; On some Recent Contributions to Mental Science, Medical Jurisprudence, and Anthropology, by G. E. Day, M. D.; Clinical Lectures delivered at the Bellevue Hospital Medical College, by W. A. Hammond, M. D.: Inaugural Address on assuming the Presidency of the New York Medico-Legal Society, by S. Rogers, M. D.; The Medico-Legal Value of Confession as an Evidence of Guilt, by Wm. A. Hammond, M. D.; with the usual variety of briefer articles and items.

The American Practitioner contains the following leading articles: A Case of Labor in connection with a Large Ovarian Cyst, by J. C. Reeve, M. D.; On Acute Rheumatism, by C. Rogers, M. D.; Treatment of Gonorrhea by Warm-water Injections, by J. O'Reilly, M. D.; Restoration of Everted Lower Lip, by D. Prince, M. D.; The Therapeutical Value of Veratrum Viride, by W. W. Dougherty, M. D.; Sulphate of Beberia in Chronic Inflammation of the Uterus.

The American Journal of the Medical Sciences (Phila.) has a table of Contents filling six pages, and including thirty-three original communications, with fifty-three briefer articles in the "Quarterly Summary of Improvements and Discoveries in Medical Science," etc., etc.

The Indiana Journal of Medicine, which has come to hand since our article on Propylamine was in type, contains a communication on "Propylamine in Rheumatism," by Dr. J. M. Gaston, in which he gives the results of several years' experience with this agent, which he thinks is "not sufficiently known and appreciated by the profession at large."

The *Boston Medical and Surgical Journal*, of April 6, has a valuable article on the Prognosis of Cataract, and the Rules by which it is Formed, by Hasket Derby, M. D.

The *Georgia Medical Companion* is a new medical monthly, edited by Drs. T. S. Powell and W. T. Goldsmith, and published at Atlanta, at \$2.00 a year. The editors appear to have the tact of condensing a large amount of valuable matter into their "Abridged Extracts and Gleanings," and all their work is well done.

The first number of Prof. Hinrichs's *School Laboratory of Physical Science* (Iowa City) is out. Teachers should send for a specimen copy of it.

Medicine.

PROPYLAMINE.

The following note regarding propylamine was written by the editor of this Journal and published in the *Boston Medical and Surgical Journal* in April, 1859. The remedy has continued to grow in favor during the past twelve years, and some physicians regard it as almost or quite a specific in acute or chronic rheumatism. It would seem that it must possess merit, else it would have dropped into disuse and been forgotten. To procure the agent, nearly *one hundred barrels* of old herring pickle are manipulated in the laboratory of J. R. Nichols & Co. every year. This is utilizing a liquid which may fairly be called a *waste product.*

Propylamine belongs to a most remarkable series of homologous bodies, of which ammonia is the starting point. Propyl, found in the first or methylic series of homologous compound radicals, is an oily liquid, boiling at a temperature of about 130° F., having the formula C_3H_7. Propylamine is formed by the addition of one equivalent of propyl to amide (NH_2), which is ammonia (NH_3) minus one atom of hydrogen. The propyl takes the place of the hydrogen atom, in ammonia, and propylamine is formed. The whole series in which it is found bear a striking resemblance to ammonia, and yet they are widely different in chemical constitution.

The first in the list, methylamine (CH_5N), is a gaseous body, largely absorbed by water, has a pungent smell like ammonia, and can hardly be distinguished from it. The next, ethylamine (C_2H_7N), is only a degree less like ammonia, being highly volatile, with a similar pungent odor. The next in order, propylamine (C_3H_9N), in physical characteristics and behavior varies still wider from ammonia; but the resemblance is still so striking, that physicians may regard the liquid as made up in part of that body, while, in fact, it is not; and, as has been remarked, its chemical constitution differs from it in a most remarkable degree. Thus the formula for ammonia is NH_3; for propylamine, C_3H_9N.

There is no department of chemistry more interesting and wonderful than that relating to these homologous compounds, and the almost infinite series to which they give rise. Their therapeutic value is imperfectly understood, and its study offers a rich field for experiment and research.

Propylamine is a clear, transparent liquid, having a pungent, ammoniacal, alkaline taste and smell. A feeling of causticity is produced when a portion is rubbed between the thumb and finger. It may be derived from a variety of sources, — from ergot, cod-liver oil, bone oil, human urine, etc.; but most properly, for medicinal purposes, from herring pickle. When a quantity of old pickle is treated with a strong solution of potassa, a pungent odor like ammonia is evolved, which is propylamine liberated from its combination with an acid in the liquid. The neutral solution must be quickly distilled, and the process continued so long as the fishy odor is observed. The distillate is then saturated with hydrochloric acid, evaporated with much care to a dry crystalline mass, then treated with absolute alcohol, until the whole of the propylamine salt is dissolved out. A second careful distillation with hydrate of lime affords a small portion of pure propylamine. I have found that nearly all that should be used for medicinal purposes comes over without the application of heat, or from slight warming. Imperfectly or unskillfully prepared, the remedy will prove worthless, while fresh specimens of *true* propylamine may possess great medicinal value.

The virtues ascribed to propylamine, in the cure of rheumatism and affections of a rheumatic origin, are extraordinary. Dr. Awenarius, of St. Petersburg, treated 250 patients in the hospitals of Kaulinkin, at St. Petersburg, between March, 1854, and June, 1856; and in acute cases the pain and fever *always disappeared the next day.* He regards it "as a true specific for the various affections of rheumatic origin." The diagnosis of these diseases being very often obscure, one can succeed (says M. Awenarius), by the use of propylamine, in bringing to light in a few days the true nature of the malady. It is stated to have been employed in outside practice with equal success.

Although the claims for the new agent may be, and probably are extravagant, still, should it be found to have, in any measure, control over the specific disease for which it is recommended, it will indeed be a blessing to a suffering class of patients, and therefore merits a trial at the hands of the profession.

The remedy is described in the following manner: ℞ Propylamine, gtts. xxv.; distilled water, fl. oz. vi.; and, when necessary, add aqua sacch. peppermint, dr. ij. *Dose*, a table-spoonful every two hours.

THE INTERNAL ADMINISTRATION OF CHLOROFORM.

Dr. G. W. Murdock, in the *Journal of Pharmacy*, after alluding to the difficulty physicians have had in finding a good vehicle for the internal administration of chloroform, recommends *pure glycerine* as one "which answers the purpose so completely as to leave little to be desired." He adds the following suggestions: —

"By a little care in rubbing it up, one part of chloroform by bulk can be dissolved in three of glycerine. This solution is perfectly clear, is bland to the taste, and has but a slight odor of chloroform.

"As glycerine is acceptable to almost every stomach, it admits of a wide range of application. It can be taken readily as it is, or can be diluted with water to any extent, without disturbing the solution. Curiously enough, the addition of water immediately increases the smell of chloroform without any precipitation of it. In preparing it, it is best to take one part of chloroform with two parts of glycerine, add the chloroform very slowly, and rub up carefully. Then put it in a bottle, and let it stand twenty-four hours. A little chloroform will have deposited at the bottom. Separate this, and rub it up with the third part of glycerine, then mix it with the rest, and the solution is complete. No further separation will take place. Six ounces of glycerine with two of chloroform will give seven fluid ounces of the solution, so that each fluidrachm contains about seventeen M. of chloroform.

"From the faint odor of the prepared solution I judge that the glycerine protects it almost entirely from evaporation, although some slight loss may occur while preparing it, which it is well to make allowance for."

GOOD LIVING IN THE TREATMENT O NERVOUS DISORDERS.

We believe that starvation in the midst of plen is no uncommon thing in our day, not only in th case of infants, but with adults also. Dr. G. Blandford has some sensible remarks on this subje in a recent number of the London *Practitione* He says: —

"If we inquire into the past history of nervou patients, and have the opportunity of learning ac curately the facts thereof, we often find that for considerable time the supply of daily food has bee in no degree adequate to the necessities of the in dividual. Here is a common case. A man som what past middle life, but whose years do not im ply senile decay, becomes unfit for business, fidget irritable, depressed, or even melancholic to the ex tent of insanity. We hear that he has been a hard working man of business, always nervous, and ver probably an indifferent sleeper. Being most heav for sleep in the morning, he has risen at the late moment, and, snatching a mouthful of breakfast, ha hurried off to catch the train or omnibus, worrie and anxious lest he fail to reach his office at th hour appointed. At lunch-time, if he be reall hard-worked, he takes, not a meal, but a sandwic or biscuit, eaten perhaps standing, and often bolte in so great a hurry that digestion is difficult he tells us that he dare not take more of a meal i the middle of the day, for he would be rendere unfit for the remainder of his work. In the even ing, with what appetite he may, he eats his dinne perhaps not before half past seven o'clock. Nov granting that his dinner is amply sufficient, such man lives on one meal a day with very little b sides. These are the persons who cannot go o without frequent holidays; nervous by inheritanc they break down because they are insufficiently fe A holiday, during which they live better, build them up again for a time, again to break down often to fall into the condition above mentioned Another class among whom we may frequently wit ness the same result and corresponding symptom are the clergymen, who for various reasons den themselves an adequate amount of food. Eithe they fast rigidly, according to the rule and doctrin of the day, often allowing some hours to elaps before they break their fast, or they think tha hearty eating is a snare and a carnal enjoyment, c they hold it sinful to eat their fill while others ar in want. Whatever the cause, certain it is tha many of the clergy break down in one or other o the forms of nervous disorder already enumerate and an enlarged dietary is to them a necessity A vast number of women, for one reason or othe take a very small supply of food; some think unladylike to eat heartily; some eat on the sly, an when this is not practicable go without. Many fro the lives they lead are doubtless correct in sayin they cannot eat because they have no appetit These stay in the house from month to month, c never venture beyond the door except in a carriag because ladies do not walk in the streets. Other have misgivings on the score of their digestio Like many women who lead sedentary lives, an habituate themselves to passing long periods with out action of the bowels, they suffer greatly fro constipation, which is looked upon as an indicatio and a warning that they ought not to eat. So the starve themselves, and fancy that if they abstai from food it is of little consequence whether the pass a motion once a week or once a fortnight."

In low nervous depression, or melancholia, Dr Blandford particularly urges the importance of full feeding. "It is not necessary," he thinks, "t adhere to a sick diet — to beef-tea or boiled mut ton, to essence of beef or Liebig's food, or any othe of the concentrations so loudly recommended. Th ordinary diet-list of the individual in health may b

ven without hesitation — fish, game, poultry, meat, ddings, and the rest. His appetite should be mulated by variety, and his dishes may be savory well as wholesome; but the supply must be large. ich patients for the most part have accustomed emselves to eat during the day a scanty and in-fficient amount, and we shall be told that latterly ey have not taken half their usual quantity. It is t to much to say that they require double that hich they have so long taken; and as we shall t be able to induce them to eat double the quan-y at a single meal, it will be necessary to multiply e number of the meals. Instead of breakfast, ich, and dinner, two of which have probably en but the semblance of a meal, we may institute a ies of feedings after this kind: first, something may given early in the morning, before the patient ts up, as rum and milk, egg and milk, chocolate, café au lait. This will be useful in allaying the ling of extreme depression, and dispelling the omy and suicidal thoughts so constantly present first waking. Next, breakfast may be taken, er dressing, and between it and the two-o'clock ich something else, as beef-tea or a sandwich. e dinner-hour should not be later than six, and bed-time some light kind of supper should not omitted. By this kind of division food may administered six times in the day; and if the ient wakes in the night, and is restless and vous, and disinclined to sleep again, food, taken en in small quantity, will often bring back sleep. th all this food may be given a reasonable ount of wine, or wine and stout, and this not way of curing the disorder by stimulants, but ause in conjunction with them less food appears be required, and also because the addition of the wine or beer often renders the taking of the d more easy to the patient.

"Now the latter, and it may be the friends, will otest loudly that it is impossible to take this quan-t: he will assign every conceivable reason for oiding it; but if we are firm and insist, and, if essary, cause him to be fed with a spoon, he will ain and thrive on it, and in a few weeks, or even s, will show very marked signs of its good effect. ients have recovered under this treatment in a gularly rapid manner."

n hysteria and neuralgia he considers the same tment required. Believing that neuralgia is one nifestation of impaired sensibility, as other neu-es may be displayed in mental symptoms, and in se alone, he thinks that the radical cure, and not mere alleviation, is to be found in many cases he supply of a large amount of nutriment to the vous system.

OFFENSIVE BREATH.

THE popular term "bad breath" is a very sig-nant expression for this unpleasant condition. at is more offensive to the acute olfactory sense n a fetid breath? It engenders a feeling of aver-sion and disgust, which is not readily overcome.

Great care should be exercised in keeping the mouth free from all extraneous substances. After each meal, a quill or ivory tooth-pick should be used to remove any aliment that may have become lodged in the teeth during the process of mastication, and the mouth rinsed with tepid soft water. Every night, previous to retiring, the teeth should be cleansed with a soft tooth-brush and water. As a rule, tooth pastes and powders should be eschewed as harmful agents. If a dentifrice is desired, a little fine toilet soap, or charcoal reduced to an impalpable powder, may be used. This is all that will be required. Decayed teeth are a very prolific source of mephitic breath. As soon as it is ascertained that a tooth is affected, it should have immediate attention from some competent dentist.

Carious teeth are often the source of serious functional and general disturbance. It sometimes occurs that persons with a number of defective teeth are constantly ailing with either gastric or nervous troubles, when, upon a removal of these unsound members, all the unpleasant symptoms promptly disappear.

It may be well to give a word of caution in regard to diet; by irregularities in eating, the digestive functions become impaired, and for want of proper digestion, the aliment undergoes zymotic change, during which process noxious gases are evolved, and cause a foul breath. When cases arise from disease, it is either of the stomach, lungs, or the respiratory passages. In these cases a physician should be consulted at once.

Many substances are in vogue to sweeten the breath, and to disguise any unpleasant scent, as of spirits, tobacco, etc. With the vulgar it is customary to use some pungent aromatic, as cloves, etc., but this savors too strongly of the drinking bar to be used by any but tipplers. The following, used as an occasional mouth-wash, will be found excellent. Take chlorate of potash, three drachms, and dissolve in eight ounces of rose or other medicated water. As an article with which to flavor the breath, there is probably nothing equal to the Wild Ginger (*Asarum Canadensis*). It is used by chewing a small portion of the root, or if in powder, it can be made into a lozenge. It imparts to the breath an agreeable, spicy aroma. — *Dental Register.*

TO PREVENT SYRUPS FROM CRYSTALLIZING.

IN reply to complaints that syrups made in the ordinary way (especially Syr. Scillæ Comp. and Syr. Senegæ) soon begin to crystallize, a correspondent of the *Druggists' Circular* recommends making them by the cold way, or by percolation. As a general rule he gives the following: "Take two (2) parts of sugar to one of menstruum (or water, if simple syrup is prepared); introduce the sugar into a percolator, into the neck of which previously has been introduced a piece of lint or sponge, and then gradually pour on the liquid so as to cause the percolate (syrup) to pass, drop by drop. If the liquid (syrup) pass too rapidly, the neck of the percolator should be obstructed by means of cork, until the requisite slowness has been obtained. (See U. S. Dispensatory, article *Percolation.*) Syrup done thus will keep for many years, and will *neither crystallize nor ferment.*"

After making most of the syrups for several years by percolation, he is satisfied that it is the best process. He adds: —

"In many syrups heat injures the medicinal property of the drug, and often the syrup is not as clear as it should be. It frequently requires purification with carbo animalis or albumen, while by percolation (if properly conducted) the syrup will be always pure, clear, and better could not be desired.

"Sometimes heat is necessary to separate the albumen of a menstruum or to evaporate the alcohol; but if that is done the residue may be mixed with water (if it can be mixed), and filtered if turbid; afterwards follow the process of percolation.

"To make the Syr. Scillæ Comp. I use the following process: Take the Squills and Senega, according to the U. S. D., macerate for 24 hours in sufficient diluted alcohol, strain and transfer it to a percolator, and pour diluted alcohol upon it until sufficient tincture shall have passed to make the measure of three pints. Boil this for a few minutes, filter while cool, and evaporate it by means of the pharmaceutical still, to the consistency of a syrup; then dissolve the tartar emetic in half an ounce of hot water, add sufficient simple syrup (prepared by percolation) to make the measure three pints. This syrup will stand any temperature and not crystallize."

COD-LIVER OIL.

DR. J. M. WINN, senior physician to St. George's and St. James' Dispensary, says in the *British Medical Journal*: —

"The following example is a remarkable illustration of the value of cod-liver oil in a case that appeared, at first sight, an unpromising one for its use.

"A child, six years and a half old, was brought to me dreadfully disfigured by an eruption of eczema impetiginodes over the forehead, nose, lips, and left cheek. She was one of the largest and most robust looking children I ever saw, and her muscles were firm and well developed. She was the daughter of Jewish parents; and I was informed that her brothers and sisters were all on the same large scale. Attributing the disease in a great measure to a plethoric condition, I prescribed aperients and alkalies; and as she was in the habit of eating very heartily of animal food, I reduced her allowance of meat. After continuing this plan for a fortnight, there was no amendment; I then changed the treatment, and ordered one small tea-spoonful of cod-liver oil three times a day. The effect was immediate, and in about a fortnight the eruption had disappeared, and the child was quite well in every respect.

"A case which I am now attending will serve to show that all the beneficial effects of cod-liver oil may be produced by the use of very small quantities, even on full-grown persons of very large proportions. The patient is an ex-Life-Guardsman, above six feet in height, suffering from tubercular disease. He appeared to be in a sinking state, but has now rallied far beyond my expectation from the use only of one drachm of the oil three times a day.

"From these and similar instances of constant occurrence, I infer that cod-liver oil does not act as a mere article of food; neither is it a simple tonic, like iron or gentian; but that it has a specific virtue of its own — in short, I would suggest that cod-liver oil is to hereditary affections what quinine is to zymotic diseases."

MEDICAL MEMORANDA.

SPONGIO-PILINE. — This is the name of an ingenious contrivance, recently introduced abroad, which may be used either as a poultice or as the means of fomentation. It consists of wool and small particles of sponge, apparently felted together, and attached to a skin of india-rubber. It is about half an inch in thickness. It retains heat for a considerable time, and by means of it vinegar, laudanum, camphor, hartshorn, etc., can be placed on the skin, accompanied by heat and moisture, much more readily, and with greater cleanliness, than by the use of ordinary poultices.

GUNSHOT WOUNDS OF THE HEART. — "Shot through the heart" is a familiar expression in connection with war and battles, but it appears from statistics to be a rhetorical rather than a literal account of the way soldiers are usually killed. Of 87,822 wounded in our late war, among which are 7,062 gunshot wounds of the thorax, 4,759 wounds of the thoracic walls, and 2,303 penetrating wounds of the chest, there were recorded only four cases of gunshot wounds of the heart.

POISON IN THE SNUFF-BOX. — There seems to be no end to the ways in which we may be poisoned with lead. Dr. Garrod, at King's College, Dublin, lately described a case in which the mineral was taken in snuff. It was rappee that the patient habitually took, and the damp snuff packed in the usual lead cases converted some of the metal into carbonate. The symptoms were serious, and with difficulty traced to their real source. Then several packages were purchased, and found to be contaminated with the poison. Snuff-takers would do well to take this important lesson to heart.

To Spread Plasters. — In spreading plasters extemporaneously, says the *Pharmacist*, convenience requires and neatness demands an uncoated marginal edge. This is usually secured by pasting strips of paper along the edges of the skin, and removing them after the spreading of the plaster is effected. It is just here that a practical difficulty frequently arises. The paper edges are liable, from drying of the paste, to adhere so strongly that either paper or skin will give way upon an attempt at their removal; the application of water will then be necessary to soften the attachment, and the final results may be expected to present a daubed and uncleanly aspect. This difficulty may be entirely avoided by applying to the paste brush a little glycerine before the adjustment of the marginal strips.

Calendula Officinalis. — Dr. A. Livezey asserts that a tincture of the flowers of marigold is vastly superior to that of arnica. He has used it for many years for all kinds of wounds, by saturating a piece of lint, and applying it to the part.

Hypophosphite of Soda. — Dr. J. C. Thorowgood thinks this salt answers all the purposes of pure phosphorus as an internal remedy, and as a gradual tonic and restorer of nerve force. In cases of nervous depression and torpor, with, at times, shooting neuralgic pains, or in other cases, numbness and deadness of the limbs, as from feeble circulation, the hypophosphites prove useful, and the lime or soda salt can be given according to the way in which the stomach may seem to bear the one better than the other. When anæmia is present, the citrate of iron can be added, or else the syrup of the hypophosphites of iron, or iron with quinine, can be employed. Either of these syrups will prove an active tonic, removing neuralgic pains, chest oppression, and languor of circulation in a very evident way.

How to Administer Raw Meat. — The *Lancet* says: "The fillet should be preferred, as being the most delicate and the richest in muscular fibrin. It should be freed with the utmost care from fat and tendon. It should be finely minced, and then brayed in a mortar of wood or stone. When reduced to a paste it should be covered with sugar, gluten, or vegetable gelatine, to overcome the repugnance with which it is at first naturally regarded. Some prefer to squeeze out the juice, and swallow it mixed with a little rum or orange-flower water; whilst others again make it into boluses, and take it in slightly warmed beef-tea or soup."

Sea-sickness. — Dr. O. Rapin, of Switzerland, says that he has found that the nausea and vomiting produced by swinging and sea-sickness can be arrested by applying to the epigastrium a layer of wadding dipped in collodion. It should extend from the xiphoid cartilage to the umbilicus, and be left until it falls off. If the adhesion should be imperfect, the application should be renewed. Several persons, he says, have tried this plan with benefit. The explanation which he gives of it is, that the action of the peripheral nerves is interrupted just in the same way as the pain of calculi in the bile-passages or ureters is sometimes mitigated by the application of castor oil and collodion.

The Title of "Doctor." — The title of "doctor" was invented in the twelfth century. Irnerius, a learned professor of law at the University of Bologna, induced the Emperor Lothaire II., whose chancellor he was, to create the title, and he himself was the first recipient of it. He was made doctor of laws by that university. Subsequently the title was borrowed by the faculty of theology, and first conferred by the University of Paris on Peter Lombard. William Gordenio was the first person upon whom the title of doctor of medicine was bestowed; he received it from the College of Asti, in 1329.

Castor Oil in California. — Though the castor bean has been cultivated in the middle and lower counties of the State for fifteen or sixteen years, it is only during the last four years that its cultivation has been conducted with a view to profit. The quantity of oil produced in 1869 was 10,000 gallons. The San Francisco Oil Works expect to produce the present year 15,000 gallons; various manufacturers in Marysville, 8,000 gallons; and others in Santa Barbara, some 4,000 gallons more, or in the aggregate 27,000 gallons, — an amount not more than sufficient to supply the home demand, which was near 25,000 gallons in 1869. The imported oils have been held at $2.25 per gallon, while that manufactured here can be furnished for $1.00 per gallon, and leave a handsome profit.

Knowledge versus Pestilence. — "The people perish for lack of knowledge," might have been the text of the "Lay Sermon" in which Huxley discourses as follows: —

"We have learned that pestilences will only take their abode among those who have prepared unswept and ungarnished residences for them. Their cities must have narrow, unwatered streets, foul with accumulated garbage. Their houses must be ill-drained, ill-lighted, ill-ventilated. Their subjects must be ill-washed, ill-fed, ill-clothed. The London of 1665 was such a city. The cities of the East, where plague has an enduring dwelling, are such cities. We, in later times, have learned somewhat of Nature, and partly obey her. Because of this partial improvement of our natural knowledge and of that fractional obedience, we have no plague; because that knowledge is still very imperfect, and that obedience yet incomplete, typhus is our companion, and cholera our visitor. But it is not presumptuous to express the belief that, when our knowledge is more complete and our obedience the expression of our knowledge, London will count her centuries of freedom from typhus and cholera, as she now gratefully reckons her two hundred years of ignorance of that plague which swooped upon her thrice in the first half of the seventeenth century."

VALUABLE FORMULÆ.

Carbolic Acid in Rubeola. — Dr. T. J. Williamson has found much advantage from the use of Carbolic Acid in malignant form of measles. In one case his prescription was as follows: —

℞	Syrp. Scillæ, c.	f. ℥i.
	Syrp. Ipecac	
	Tinct. Lobelia Inf. āā	f. ʒi.
	Carbolic Acid	gtt. xvj. M.

S. Teaspoonful every hour.

And as a wash for mouth —

℞	Carbolic Acid	℈ii.
	Chlo. Potass.	℈i.
	Mellis desp.	℥ss.
	Aq. Camph.	f. ℥ii. M.

S. Gargle the mouth every three or four hours.

Eye Salve for Granular Lids and Chronic Ophthalmia. — Dr. John Williams, in the *Dublin Quarterly Journal of Medical Science*, writes thus: "After long experience I can speak most confidently of this ointment, for the composition of which I now publish the following formula: ℞ Arsenici Sulphureti, 2 gr.; Unguenti Citrini, 2 ʒ; Axungiæ Preparat., 6 ʒ. M. Bene. In cases of 'granular lids,' accompanied with most inveterate 'pannus,' and in almost all cases of chronic ophthalmia, in which the conjunctiva has become almost cuticular, I have found this ointment particularly useful. Ophthalmia is well known to be very prevalent in the city and county of Cork, so that I had very many opportunities of proving the efficacy of this ointment. The upper eyelids should be everted in cases of 'granular lids,' and about the size of a hemp-seed of this ointment should be applied with a camel-hair pencil, which must be introduced into the superior palpebral sinus, to the diseased conjunctiva."

Glycerine in Phthisis. — In the early st[age] of Phthisis the following is highly recommended —

℞	Glycerine	℥ii.
	Iodid. Potass.	ʒi.
	Sulph. Morphiæ	grs. ii. M.

S. A teaspoonful before each meal, and at [be]d time. In the advanced stages, the following is [pre]ferred: —

℞	Glycerine	℥ii.
	Syrp. Iodidi Ferri	℥ss.
	Sulph. Morphiæ	grs. ii. M.

S. Teaspoonful every four or six hours.

Glycerine will be found to be the best solv[ent] when prescribing medicines in liquid form. [It] should always be used in place of syrup, w[hen] medicines are to be given in this way to child[ren]. It never ferments. The best article should be u[sed].

Prescription for Chronic Bronchitis.

℞	Ammoniaci	ʒi.
	Pulv. Ipecac	gr. x.
	Mur. Morphiæ	gr. iv.
	Carb. Ammoniæ	ʒii.
	Mucilaginis Acaciæ	q. s.
	Misce et divide in pilulas	xxx.

Sig. — Give one pill, three times a day, in c[as]e attended with viscid bronchial secretion.

Prof. Van Buren's Pill for Constipati[on].

℞	Extracti Aloes	ʒss.
	Extracti Nucis Vomicæ	gr. vi.
	Extracti Hyosciami	℈i.
	Pulv. Ipecacuanhæ	gr. l. M.

Make pills xx. S. One to be taken at n[ig]ht. This pill is of especial value in the constipatio[n] of females.

APPROVED COSMETICS.

GLYCERINE BALSAM.

This is designed to whiten and soften the s[kin], remove roughness, chaps, chilblains, and irrita[tions] from common causes.

Take white wax (pure)	1 ounce.
Spermaceti	2 ounces.
Oil of almonds	9 "

Melt together by a moderate heat in a glazed ea[rth]enware vessel, and add

Glycerine (best)	3 ounces.
Balsam of Peru	½ ounce.

The mixture is to be stirred until nearly cold, a[nd] then poured into pots. [Instead of balsam of P[eru], 12 or 15 drops of ottar of rose may be employed.]

BALSAM OF HONEY.

Take fine pale honey	4 ounces.
Glycerine	1 ounce.

Mix by a gentle heat; when cold add

Alcohol	1 ounce.
Essence of ambergris	6 drops.
Citric acid	3 drachm[s].

This is intended to remove freckles and discolo[ra]tions, as well as to improve the general appear[an]ce of the skin.

COLD CREAM.

Take white wax, Spermaceti, of each	1 ounce.
Oil of almonds	¼ pint.

Melt, pour the mixture into a Wedgewood mo[rtar] which has been heated by being immersed in [hot] water; add gradually

Rose water	4 fl. ou[nces].

and stir until an emulsion is formed, and afterw[ar]d until the whole is nearly cold. Put in pots. It may be perfumed with bergamot or lavender. — *Druggists' Circular.*

Counter Practice. — The *Boston Medical* [an]d *Surgical Journal* calls the attention of apotheca[ries] to an excellent example afforded by one of t[he]ir own number, in whose shop is conspicuously pla[ce]d the notice: "We are pharmacists, but not phy[si]cians; we dispense medicines, but do not presc[ribe] for diseases."

Boston Journal of Chemistry.

VOLUME V. BOSTON, JUNE, 1871. NUMBER 12.

Familiar Science.

CHEMISTRY OF A HEN'S EGG.

IT is presumed that but few of those who break the shells of the cooked eggs of our common domestic fowls, at the breakfast table, ever think of the wonderful nature of the structure they crush, or of the complex chemical nature of the contents consumed as food. To a large majority of people, an egg is an egg, and nothing more. If the multitude were inclined to inquire into the composition of this curious embryotic substance, the impatience of hunger which universally prevails at the commencement of the morning meal, would render the hour quite unpropitious, and therefore we hardly expect to secure the reader's attention until the time arrives for lighting the evening lamp.

Before proceeding to inquire into the interior composition of the egg, we will consider the exterior covering, or the shell, the physical and chemical structure of which is exceedingly interesting and wonderful. The white, fragile cortex called the shell, composed of mineral matter, is not the tight, compact covering which it appears to be, for it is everywhere perforated with a multitude of holes, too small to be discerned by the naked eye, but which with the aid of a microscope are distinctly revealed. Under the microscope the shell appears like a sieve, or it more closely resembles the white perforated paper sold by stationers. Through these holes there is constant evaporation going on, so that an egg, from the day that it is dropped by the hen to the moment when it is consumed, is losing weight, and diminishing in volume. This process goes on much more rapidly in hot weather than in cold, and consequently perfect eggs are not so readily procured in summer as in winter. If by any means we stop this evaporative process, the egg remains sound and good for a great length of time. Covering the shell with an impervious varnish, or with mutton suet, or lard, aids greatly in their preservation. The substance used to stop transpiration must not be soluble in watery fluids, or liable to be readily removed. By chemical agencies, that is, by actually filling up the little holes in the shell by lime placed in contact in solution (the solution holding the proper chemical substances to form an impervious coating of carbonate of lime over the entire surface), we have preserved eggs for months and even years in a sweet condition. Not long ago, eggs broken in our laboratory were found to be quite fresh, which according to the memorandum made upon the vessel, were placed in the solution in May, 1867.

The shell of the egg is lined upon its interior everywhere, with a very thin but pretty tough membrane, which, dividing at or very near the obtuse end, forms a small bag which is filled with air. In new-laid eggs, this follicle appears very little, but it becomes larger when the egg is kept. In breaking an egg this membrane is removed with the shell, to which it adheres and therefore is regarded as a part of it, which it is not.

The shell proper is made up mostly of earthy materials, of which 97 per cent. is carbonate of lime. The remainder is composed of two per cent. of animal matter, and one of phosphate of lime and magnesia. Carbonate of lime is the same material of which our marble quarries and chalk beds are composed; it is lime, or oxide of calcium, combined with carbonic acid, and is a hard insoluble mineral substance, which does not appear to form any portion of the food of fowls. Now, where does the hen procure this substance with which to form the shell? If we confine fowls in a room, and feed them with any of the cereal grains, excluding all sand, dust, or earthy matter, they will go on for a time and lay eggs, each one having a perfect shell, made up of the same calcareous elements. Vauquelin, the distinguished chemist, shut up a hen ten days, and fed her exclusively upon oats, of which she consumed 7,474 grains in weight. During this time four eggs were laid, the shells of which weighed nearly 409 grains; of this amount 276 grains was carbonate of lime, $17\frac{1}{2}$ phosphate of lime, and 10 gluten. But there is only a little carbonate of lime in oats, and from whence could this 409 grains of the rocky material have been derived? The answer to this question opens up some of the most curious and wonderful facts connected with animal chemistry, and affords glimpses of many of the operations of organic life, which, to the common mind, seem in the highest degree paradoxical and perplexing. The body of a bird, like that of a man, is but a piece of chemical apparatus, made capable of transforming hard and fixed substances into others of a very unlike nature. In oats there is contained phosphate of lime, with an abundance of silica, and the stomach and assimilating organs of the bird are made capable of decomposing or rending asunder the lime salt, and forming with the silica a silicate of lime. This new body is itself made to undergo decomposition, and the base is combined with carbonic acid, forming carbonate of lime. The carbonic acid is probably derived from the atmosphere, or more directly perhaps from the blood. These chemical changes among hard inorganic bodies are certainly wonderful when we reflect that they are brought about in the delicate organs of a comparatively feeble bird, under the influence of animal heat and the vital forces. They embrace a series of decomposing and recomposing operations which it is difficult to imitate in the laboratory. In the experiment to which allusion has been made, the amount of earthy material found in the eggs and the excrement of the hen exceeded that contained in the food she consumed. This seems paradoxical, and can only be explained upon the ground that birds as well as animals have the power in times of exigency, of drawing upon their own bodies for material which is required to perform necessary functions.

The shell of an ordinary sized hen's egg weighs about 106 grains, that is, the inorganic portion of it; and if a bird lays 100 eggs in a year, she produces about 22 ounces of nearly pure carbonate of lime in that period of time, which would afford chalk enough to meet the wants of a farmer, or perhaps even of a house carpenter of moderate business, for a twelvemonth.

If a farmer has a flock of one hundred hens, they produce in egg-shells about 137 pounds of chalk annually; and yet not a pound of the substance, or perhaps not even an ounce, exists around the farm-house within the circuit of their feeding grounds. This is a source of lime production not usually recognized by farmers or hen fanciers, and it is by no means insignificant. The materials of the manufacture are found in the food consumed, and in the sand, pebble-stones, brick-dust, bits of bones, etc., which hens and other birds are continually picking from the earth. The instinct is keen for these apparently innutritious and refractory substances, and they are devoured with as eager a relish as the cereal grains or insects. If hens are confined to barns or outbuildings, it is obvious that the egg-producing machinery cannot be kept long in action, unless the materials for the shell are supplied in ample abundance.

Within the shell the animal portion of the egg is found, which consists of a viscous colorless liquid called albumen, or the *white*, and a yellow globular mass called the vitellus, or *yolk*. The white of the egg consists of two parts, each of which is enveloped in distinct membranes. The outer bag of albumen, next the shell, is quite a thin watery body, while the next which invests the yolk, is heavy and thick. But few housekeepers who break eggs ever distinguish between the *two whites*, or know of their existence even. Each has its appropriate office to fulfil during the process of incubation or hatching, and one acts, in the mysterious process, as important a part as the other. If we remove this glairy fluid from the shell and place it in a glass and plunge into it a strip of reddened litmus paper, a blue tinge is immediately produced, which indicates the presence of an alkali. The alkali is soda in a free condition, and its presence is of the highest consequence, for without it the liquid would be *insoluble*. A portion of the white of egg when diluted with water, and a few drops of vinegar or acetic acid added to it, undergoes a rapid change. The liquid becomes cloudy and flocculent, and small bits of shreddy matter fall to the bottom of the vessel. This is pure albumen, made so by removing the soda held in combination by the use of the acid. A pinch of soda added to the solid precipitate redissolves it, and it is again liquid. There is another way by which the albumen is rendered solid, and that

is by the application of heat. Eggs placed in boiling-hot water pass from the soluble to the insoluble state quite rapidly, or in other words, the albumen both of the white and the yolk becomes "coagulated." No contrast can be greater than that between a boiled and unboiled egg. Not only is it changed physically, but there is a change in chemical properties, and yet no chemist can tell in what the change consists. It is true, the water extracts a little alkali, and a trace of sulphide of sodium, but the abstraction of these bodies is hardly sufficient to account for the change in question.

The hardening of the albumen of egg by heat constitutes the cooking process, and this deserves a moment's consideration. Great as is the physical and chemical difference between a fully cooked and an uncooked egg, it is no less remarkable in the degree of digestibility conferred upon it by the process. Uncooked, it passes by the most simple processes of assimilation from the digestive to the nutritive and circulatory organs, and is at once employed in nourishing or sustaining the bodily functions. Unduly cooked, the egg resists the action of the gastric juices for a long time, and becomes unsuited to the stomachs of the weak and dyspeptic. A raw or soft-boiled egg is of all varieties of food the most concentrated and nourishing; a hard-boiled egg is apt to trouble the digestion of the strong and healthful, and its nutrient properties are sensibly impaired.

The yolk contains water and albumen, but associated with these is quite a large number of mineral and other substances which render it very complex in composition. The bright yellow color is due to a peculiar fat or oil, which is capable of reflecting the yellow rays of light, and this oil holds the sulphur and phosphorus which abound in the egg. If the yolk be removed and dried, and the yellow oil separated, it will be found to form two thirds of the substance. The whole weight in its natural state is about 300 grains, of which three fifths is water; of the white, more than three quarters is water.

The yolk and albumen of a fecundated egg remains as sweet and free from corruption during the whole time of incubation as it is in new-laid eggs, and there is but little loss of water, whereas an unfecundated egg passes rapidly into putrefactive decay and perishes.

Any one who eats three or four eggs at breakfast, consumes that number of embryo chicks. All the materials which enter into the legs, bones, feathers, bill, etc., of the new-born chick exist in the egg, as nothing is derived from outside. The little creature which has just pecked his way out of his calcareous prison-house, has lime and phosphorus in his bones, sulphur in his feathers, iron, potash, soda, and manganese in his blood, all of which mineral constituents came from the egg, and are taken into the stomach when it is eaten as food. The valuable or important salts are contained in the yolk, and hence this portion of the egg is the most useful in some forms of disease. A weakly person, in whom nerve force is deficient and the blood impoverished, may take the yolks of eggs with advantage. The iron and phosphoric compounds are in a condition to be readily assimilated, and although homeopathic in quantity, nevertheless exert a marked influence upon the system. The yolks of eggs, containing as they do less albumen, are not so injuriously affected by heat as the white, and a hard-boiled yolk may be usually eaten by invalids without inconvenience. The composition of a fresh egg, exclusive of the shell, may be presented as follows: —

Water	74	parts
Albumen	14	"
Oil or fat	10.5	"
Mineral salts	1.5	"
	100	

The whole usually weighs about a thousand grains, of which the shell makes a tenth part. The chick-making materials, exclusive of water, form only one quarter of the weight of the liquid contents, or only about 200 grains. This seems to be a small beginning upon which to rear the full-grown rooster. The bulk or quantity, as found in hens' eggs, and indeed in the eggs of all birds, is wonderfully disproportionate to the size of the mother bird. The laying of eggs must be regarded as a particularly exhausting process, and yet fowls will keep it up for a long time and not lose much in flesh. We have a hen of the *game* variety, which has this spring laid 22 eggs in 22 consecutive days, and they average in weight 1,000 grains each. This gives in amount 22,000 grains, or rather more than three pounds avoirdupois, of which about two and a quarter pounds is water. The dozen or more ounces of rich nutritive material, parted with in 22 days, would seem to be a prodigious draught upon the small physical structure of the bird, but there were no indications of exhaustion.

Whilst it is true that the quickening of an egg which results in the birth of a chick, is no more marvelous a process or result than the embryotic development of any creature endowed with the mysterious principle of life, yet there are some circumstances connected with it which make it a matter of greater perplexity and wonder. Here is an oval white body consisting of a calcareous shell, within which there are some semi-fluid substances, consisting mainly of albumen and water, without any signs of life. In fact there is no life; it is simply a mass of dead inanimate matter. Talk as much as we will about the germinal principle involved in the structure of the egg, we are totally unable to recognize it, or form any conception of its nature. There is no evidence of the presence of any germ, or principle of life whatever. The egg left to itself decays like other organized substances, but with our assistance in simply transferring it to a place where the temperature is kept in a certain uniform condition, in a few weeks the albumen, water, oil, and mineral salts are transformed into a living chick, which thrusts its little beak through the shell, and in ten minutes is running about almost able to take care of itself. Here is the development of life apparently without the agency of the mother, and what a marvel! The chemist may place together in a body, in a warm place, just such elements or substances; he may carefully weigh the water, the albumen, the phosphatic compounds, the sulphur, the iron, soda, etc., and construct a very accurate egg mixture, but out of it all there will never come a living chick. In this we obtain some idea how little we actually know about *life*, how dark is the region where the life principle begins, or where the vital forces originate. The indefatigable man of science has pushed his inquiries close up to the boundary between the inanimate and the animate, but he has never been able to obtain the least glimpse of anything upon the *life* side of the line. However great may be our curiosity, our skill, or knowledge in this state of existence, there is not the least probability that we shall ever be able to endow matter with life, or know much more than we do at present of its origin or nature.

THE LAST DAYS OF ALCHEMY IN GERMANY.

In the last number of the Journal we gave some account of James Price, whose strange story with its tragical ending forms the concluding chapter in the history of alchemy in England. We intimated that in Germany the career of the occult science was terminated in rather a farcical way, and we will try to tell the story briefly in the present article.

At the very time when Price was making his experiments in the transmutation of metals, there lived at Halle a learned professor of theology, by the name of Semler. He had heard of the marvels of alchemy in his youth, from a friend of his father, and the subject never ceased to interest him. His favorite recreation, after the labors of his professorship in the University, was working in a chemical laboratory that he had fitted up in his house. But after a time he became disgusted with the unprofitable pursuit, and gave it up wholly. Some years later, a Baron Hirschen made a great sensation in Germany with what he called the "salt of life," one of those "universal medicines" such as are not unknown even in this enlightened age, when thousands who wonder that people were ever deceived by the pretensions of alchemy become the ready victims of the latest quack with his infallible cure-all. Semler tried some of the salt of life, and feeling better for the dosing, sat down and wrote three ponderous treatises on its marvelous properties; even as grave divines sometimes indite extravagant "puffs" of the panaceas most in vogue in these latter days.

So wonderful did the medicinal salt appear to Semler, that he imagined it might prove to be the veritable philosopher's stone for which the alchemists had vainly sought. He determined to test its possibilities in that direction, and fitted up his long-neglected laboratory for the investigation. Meanwhile he dissolved some of the salt in pure water, and set the earthen vessel containing the solution near a stove, to see what effect a moderate heat would have upon it. On looking into the vessel a day or two later, he was surprised to see a few thin scales of a yellowish metal lying at the bottom. Eagerly testing them, he found them to be pure gold! There could be no doubt about it: here was the precious substance, obtained, not, as the alchemists had predicted, by the transmutation of the baser metals, but rather according to the theories of Hermes Trismegistus, by generation. But Semler was a cautious man, and was not satisfied that he had made a great discovery, until he had repeated the experiment several times, which he did with the same remarkable result. Convinced at last that gold was actually generated in a solution of the salt of life, and being no less conscientious than cautious, he wrote a minute account of his experiments to Hirschen, to whom he considered that the advantages of the discovery rightfully belonged. But Hirschen, though a quack, was evidently no fool, and wrote

back to Semler that he had better attend to his theological duties, and not meddle with matters that he did not understand.

Thus ungratefully snubbed, Semler thought it his duty to publish his discovery to the world. He did so, and the salt of life became more than ever in demand throughout all Germany. In nearly every house a pot of it might be seen beside the fire. In vain, however, did these household alchemists look for gold to appear in the simmering solution. That lucrative result was manifested in Semler's earthen pot again and again, but nowhere else.

What could be the cause of this? A German professor never confesses a problem to be insoluble, and Semler wrote a lengthy and learned treatise to prove that he obtained gold, while others did not, because he had maintained in the experiment that perfect regularity of temperature which was requisite, by fecundating the salt, to generate the precious metal. But Klaproth, the most eminent chemist of the day, having analyzed the salt of life, found it to be nothing but a mixture of sulphate of soda and sulphate of magnesia (Glauber's salt and Epsom salt), which of course could not produce gold under any circumstances whatever. Thereupon Semler sent Klaproth some of his salt of life, in powder and in solution, and in both of these gold was found upon analysis. Here was a mystery; for Semler's character was such that no reasonable man could suspect him of wilfully deceiving others, while, on the other hand, it did not seem possible that he could have deceived himself. A bitter controversy ensued between the friends and partisans of the theologian on the one hand, and those of the chemist on the other; and, to settle it, Klaproth at last consented to analyze Semler's solution at Berlin in presence of the King's ministers and other distinguished persons.

The result developed a new mystery. Klaproth found no gold in the solution, but he did find a kind of brass, or "Dutch metal," as it is now called. This new offspring of Semler's "fecundated" liquid was laughed at as a good joke; but the government was not inclined to let it pass in that way. An investigation was made by the police, and the enigma was soon disentangled. Semler had an old servant, who, for the sole purpose of gratifying his beloved master, used to drop bits of gold-leaf slily into the pot by the fire. Having to be away from home for a few days, he entrusted the secret to his wife, and gave her money to buy the gold-leaf that would be needed to keep up the alchemy in his absence. But the worthy *frau* had a weakness for brandy, and thinking that tinsel would do as well for the professor's solution as gold-leaf, bought the former instead of the latter, and so saved an honest penny for her private potations. In Shakespeare's day, as the reader may know, wine was sometimes facetiously called the "grand elixir" of the alchemists; and "gilded" (as you may see by reference to the last scene of *The Tempest*) was another name for *drunk*. Now, just at the time when the good woman was "gilding" herself, instead of putting the gold into her master's mixture, the public analysis by Klaproth took place, and the pinchbeck was therefore found in place of the pure metal.

Semler had the good sense to join in the laugh when the real nature of his alchemy was exposed, instead of writing another heavy disquisition to justify himself, or drinking laurel-water, like Price, to escape the humiliation that would be connected with a frank confession of his error. Alchemy never recovered from the effects of the blow, being fairly laughed out of its feeble remnant of life; but the excellent theological professor, though he may have shut up his laboratory again in disgust, did not probably suffer materially in reputation, — that is, as a theologian and as a man.

GOLD AND GEOLOGY.

That theory may sometimes prove only a blind guide, and that a joker may sometimes have the laugh turned against himself, is the double "moral" of the following good story, told by a writer in *Lippincott's Magazine* for May: —

"In the earliest days of gold-mining we established certain auriferous geological laws. It was legitimate that gold should be found only in certain locations on the river bank, in the bed, in gulches or flats, on riffles and bars. But gold was no respecter of these laws. There is near Columbia, Tuolumne County, a very large flat, over a mile in diameter, and perhaps four in circumference. It has been immensely rich. It is surrounded on all sides by hills. One day, some nineteen or twenty years ago, a negro walked over this flat. He had just arrived in the country: he had come to dig for gold. He approached a party of miners at work, and asked them where he had better dig. These were geological miners. They held that gold should be found only in flats and low places. They were also white miners. White miners some nineteen years ago felt themselves at full liberty to expend their rough humor over a solitary inquiring negro: so they told him that good diggings might be found up on yonder hill, pointing to one of the highest in the neighborhood, as yet untouched by pick or shovel. It was a good joke thus to send Ethiopia up the barren hill that hot summer's day, the mercury standing at one hundred in the shade. Ethiopia confidingly went, dug, perspired, and opened one of the richest claims in Tuolumne.

Caucasia heard of it. The grin faded from her features. She dropped her picks and shovels, ran from the plain, ran up that hill, and in twenty-four hours it was entirely staked out in claims. Ethiopia had some trouble in preserving the integrity of his own legitimate mining boundaries. Caucasia ever after that was careful how she joked with inquiring negroes as to the locality of 'diggins.' She also lost confidence in her geology."

A SPIDER'S ENGINEERING.

In 1830, at Newcastle-on-Tyne, England, a gentleman boasted to a friend that he could introduce to him an engineer of more wonderful skill than Robert Stephenson, who had just made himself famous by perfecting the railway locomotive. In fulfillment of the boast he brought out a glass tumbler containing a little scarlet-colored spider, whose beauty, with its bright yellow nest on a sprig of laurustinus, had induced a young lady to pluck it from the bush where it was growing. When brought into the house, it was placed on the mantel-piece, and secured by placing a glass over it.

In a very short time, this wonderful little engineer contrived to accomplish the herculean task of raising the sprig of laurustinus, a weight several hundred times greater than itself, to the upper part of the glass, and attaching it there so firmly that, after forty years, it is still suspended where it was hung by the spider.

In the Bible we read: "The spider layeth hold with her hands, and is in kings' palaces;" but in its glass prison there was nothing for it to lay hold of — no peg, or nail, or beam, on which to fasten its threads; yet in a short time the little insect had nearly filled the interior of the glass with minute, almost invisible threads, by means of which it had accomplished its task.

It is believed that this kind of spider always deposits its nest upon trees, and never upon the ground; and this may account for its wonderful effort to raise the branch to the upper part of the glass.

It may still be seen, dead and dry, hanging by one of its threads from the top of its prison house, with its little nest upon a leaf of the laurustinus.

HINTS FOR THE LECTURE-ROOM.

Fluorescence. — Professor Fluckiger, of Berne, has discovered a liquid that shows the phenomena of fluorescence in a very remarkable manner. If about 70 drops of the essential oil of peppermint be shaken with one drop of nitric acid, sp. gr. 1.2, the fluid turns faintly yellow; it then becomes brownish, and after an hour or two exhibits a most beautiful blue violet, or greenish blue color when examined in transmitted light. When observed in reflected light, the liquid is of a copper color, and not transparent.

To Solidify Carbonic Disulphide. — A German chemical journal describes a very simple method of solidifying bisulphide of carbon, which usually requires a temperature of —90° C. This is effected by sending a rapid current of very dry air over the surface of the pure liquid contained in a glass vessel. If, to water contained in a capsule, a little bisulphide of carbon is added, it may be rapidly converted into ice by driving a current of dry air over it.

To Show the Reaction of Ozone. — A Russian chemist has devised a simple experiment for this purpose. Invert a Hofmann eudiometer, and after connecting the platinum wires with an induction apparatus pass oxygen gas slowly through the tube, and then through Liebig's potash bulbs, in which is a solution of iodide of potassium and starch. The presence of the ozone will presently be shown by the liberation of the iodine and the bluing of the starch.

USEFUL RECIPES.

Gall-Soap. — Gall-soap, for washing fine silk and ribbons, is prepared in the following manner: In a vessel of copper one pound of cocoa-nut oil is heated to 60° Fahr., and half a pound of caustic soda is added with constant stirring. In another vessel, half a pound of white Venetian turpentine is heated, and when quite hot, stirred into the copper kettle. This kettle is then covered and left for four hours, being gently heated, after which the fire is increased until the contents are perfectly clear, when one pound of ox-gall is added. After this, good, perfectly dry Castile soap is stirred into the mixture until the whole will yield but little under the pressure of the fingers; for which purpose, from one to two pounds of soap are required for the above quantity. After cooling, the soap is cut into pieces. It is excellent, and will not injure the finest colors.

Lacquering Varnish. — A varnish recommended as well adapted for lacquering pictures and engravings, as well as for preserving dried plants and flowers, is prepared by pounding up ten ounces of gum sandarac, four ounces of mastic, and half an ounce of camphor, and adding three quarts of strong alcohol. The mass is to be frequently shaken up, and finally placed in a warm situation until it settles. Plants coated with this varnish will, it is said, be protected from destruction by insects, and will retain their colors fresh and unchanged. This

varnish does not peel off, and, therefore, can be applied very thin.

To Keep Butter Sweet. — No better plan has ever been devised than to put it in clean *jars* and cover it with strong brine. No kind of vessel, cask, or tub, will answer as well as the jar. In this way it can be kept fresh and sweet for twelve months.

CULINARY HINTS FROM FOREIGN SOURCES.

Norwegian Oatmeal Porridge. — Take two or three handfuls of meal, mixed, coarse and fine, in proportion of one third latter to two of the former. Mix in a basin of cold water and pour into a pan containing about a quart of boiling water, adding a small portion of salt. Set on the fire, and keep stirring, adding from time to time small doses of meal until it boils and has acquired a proper consistency; which may be known by its glutinous state, as it drops from the spoon. Let it simmer ten minutes, then pour into common dinner plates. Spoon out portions, and float in new milk, adding sugar to taste.

Fish Macaroni. — *Land and Water* gives the following, to be made from the fish left from the day before, or from fresh fish of any kind: Take equal quantities of cold or freshly cooked fish, free from bones, and boiled macaroni; mix them well together, with a good quantity of grated cheese, and pepper and salt; put the whole in a flat dish, and smooth it over, put on the top a few small pieces of butter, and grate some more cheese over it; brown it well before the fire, and serve it up very hot.

A Diabolical Dish. — The same journal gives the subjoined receipe for what is known among British epicures as "the Devil": "Roast a leg of mutton until it is three parts done; then take it from the fire, and score it to the bone in slices about half an inch thick, but do not detach them from the bone. Mix together some cayenne pepper, salt, nutmeg, mace, and dried herbs (such as thyme, marjoram, etc.), all pounded. Season the mutton well between each two slices with this mixture; then put it in the oven for half an hour, and baste it well with butter, at first. When you take it out of the oven, lift it off the dish, and put it on another one. Take the gravy that has run from the meat whilst in the oven, add to it four glasses of good port wine, half a pint of good gravy, a little mushroom ketchup and Harvey sauce, and boil all together for two or three minutes. Pour this over the leg of mutton, and you will say it is indeed *un bon diable*." A dyspeptic, we fancy, would find it *un diable* without the *bon*.

An Excellent Turkish Pillau. — Under this head, the *Food Journal*, which gives only the most approved formulæ of the kind, furnishes the following: "Chop up 1 lb. of good mutton, put it in a saucepan, with ½ lb. of fresh butter; set it on the fire and let the meat stew a nice brown; add 1 lb. of the best rice (well washed), 2 pints of hot water, sufficient salt, and a pinch or two of cinnamon, and let it boil slowly till there is no liquor remaining; then take it off and place on the hob with the cover on it, for 20 or 30 minutes; dish it up in a dome shape, and serve hot."

Lettuce Dressing. — This is also from the *Food Journal:* "For a family of six, boil three eggs for ten minutes, throw them into cold water for a minute, peel off the shells, cut and mash them fine, and mix with them two tablespoonfuls of melted butter or sweet oil, two teaspoonfuls of mustard prepared as for meats, a dash of pepper, and a little salt. Cut the lettuce fine, pour over it vinegar, and sprinkle sugar to taste, then mix with it the prepared egg. This dish is as appetizing as it is nutritious and delightful."

While gold is worth seventeen dollars per ounce, fine blonde hair readily commands twenty-five.

The Arts.

COMPRESSED AIR AS A MOTOR.

In a former number of our paper, we referred to the proposition for transmitting the water-power of Niagara Falls to a distance through the medium of compressed air. This comparatively new form of motive power, which was tested with such satisfactory results in the operations at the Mont Cenis tunnel, appears to be attracting attention in England. At the Holmes Colliery, near Rotherham, both the pumping and the coal hauling are now done by means of it. The pumping apparatus is thus described in an English journal: —

"The air is compressed on the surface by a double-cylindered steam engine, with 18 inch cylinder and 3 feet stroke, with two air-compressing pumps, 20 inches in diameter and 3 feet stroke, worked direct from the steam engine. Near this steam engine is placed a large air receiver, while corresponding with this in the mine, at a distance of nearly one mile, are three receivers connected by short cast-iron pipes, so as to form one, this plan being found necessary in order that the receivers could be made on the surface, and connected in the pit without riveting, as safety-lamps are exclusively used at the colliery. At this part of the mine also is an air engine with two cylinders, each 14 inches in diameter, with a 12 inch stroke, working two double-acting force pumps 5 inches in diameter, with a 12 inch stroke. The compressed air is conveyed from the compressing engine on the surface to the air engine in the mine in 7 inch cast-iron pipes. The discharge pipes of the pumping apparatus worked by this compressed air are 5 inches in diameter and nearly 1,000 yards long, having a vertical lift of nearly 100 yards. The apparatus was first worked on the 6th of January last, and the steam engine was worked at the rate of fifty strokes per minute, a uniform pressure of 25 lbs. per inch being maintained for eight hours at the surface and at the underground receiver. The air engine was worked during that time at the rate of fifty strokes per minute, 260 gallons of water per minute being raised."

THE PERFECTION OF MODERN TOOLS.

Smiles, in his "Iron Workers and Tool Makers," after referring to the fact that, fifty years ago, it was a matter of great difficulty to set a new steam engine to work, and to keep it going after it was started up, the foreman of the factory at which it was made having "almost to live beside the engine for a month or more," proceeds to speak as follows of the machinery of our day: —

"Now, the case is altogether different. The perfection of modern machine tools is such that the utmost possible precision is secured, and the mechanical engineer can calculate on a degree of exactitude that does not admit of a deviation beyond a thousandth part of an inch. When the powerful oscillating engines of the *Warrior* were put on board that ship, the parts, consisting of some 5,000 separate pieces, were brought from the different workshops of the Messrs. Penn & Sons, where they had been made by workmen who knew not the places they were to occupy, and fitted together with such precision that so soon as the steam was raised and let into the cylinders the immense machine began as if to breathe and move like a living creature, stretching its huge arms like a new born giant; and then, after practicing its strength a little, and proving its soundness in body and limb, it started off with the power of above a thousand horses to try its strength in breasting the billows of the North Sea."

MEMORANDA IN THE ARTS.

A New Source of Commercial Albumen. — The *Manufacturers' Review* (whose original translations from foreign journals are always interesting and valuable) gives an account of Grüne's process for obtaining albumen from a new source; namely, the roes of fishes, which, like the eggs of birds, are rich in this important compound. The roe is cut open and the eggs squeezed out; when a sufficient number of the latter have accumulated they are thrown upon a wire sieve, and are rubbed down with a hard brush. The liquid albumen runs through the sieve, while the cellular tissue remains behind. The latter is washed slightly with water, to which 0.3 per cent. of ammonia has been added. The coagulated solution is permitted to stand a few days in tall vessels, which are provided with wooden stop-cocks at different heights; by that time the solution will have settled, when it is poured into shallow pans and evaporated in well ventilated specially constructed drying chambers. Sometimes the solution will have to be filtered through coarse sand or powdered glass in order to clear it. Albumen, obtained in this manner from fresh water fish, is very fine, clear, and devoid of smell, if prepared with due care; but salt water fish must be worked up when still fresh, as otherwise it will have a slight disagreeable odor.

Iron Telegraph Posts. — These have been introduced with great success in Switzerland, and are now being extended daily. They have been already put up on Swiss railways a distance of 350 miles. In Prussia they have been placed experimentally on the railway from Weissenfels to Gera, and on the line between Berlin and Potsdam. As iron is now so cheap, it is considered that in a short time they will altogether replace the old wooden poles in Germany, that cause so frequent interruptions to telegraphic communication from rotting or being blown down by every high wind, especially in exposed situations.

Test for Silver in the Plating of Metal. — According to Dr. Boettger, a cold saturated solution of bichromate of potassa in nitric acid (sp. gr. 1.2) is applied to the metallic surface (which must be perfectly clean) by means of a glass rod, and immediately washed off with some cold water. If pure silver is present, there will appear clearly a blood-red colored mark (chromate of silver). Upon German silver the test liquid appears brown, but after washing with water the blood-red colored mark does not appear; the so-called Britannia-metal is colored black; on platinum no action is visible; metallic surfaces coated with an amalgam of mercury yield a reddish speck, which, however, is entirely washed off by water; on lead and bismuth the test liquid forms a yellow-colored precipitate; zinc and tin are both strongly affected by this test liquid, which, as regards the former metal, is entirely removed by water, while, as regards the latter, the test liquid is colored brownish, and the addition of water produces a yellow precipitate which slightly adheres to the tin.

To Dissolve Shellac Quickly. — White shellac may be readily dissolved in the following manner: Put the shellac with some naphtha or spirits of wine into a wide-mouthed bottle, and fix the bottle in a lathe. By keeping it continually but slowly revolving, it will dissolve in about six hours. White shellac, mixed with brown, makes a liquid glue impervious to moisture, while the former alone makes a good cement for mending glass or porcelain.

An Alloy that will adhere to Iron and Steel. — It is often desirable to combine steel or iron with brass, and thus obviate the necessity of using bolts or screws for fastening them. The unequal expansion of the metals is the great obstacle to such a combination, as it overcomes the adhesion

of the surfaces and thus prevents a permanent union. The following alloy, however, adheres firmly to iron and steel, and can be recommended: 3 parts of tin, 39½ parts of copper, and 7½ of zinc.

AMERICAN ICE MANUFACTURE. — The New Orleans ice-factory runs six machines, each costing $25,000 in gold, and freezes sixteen tons of ice daily. The water is pumped from the Mississippi, purified, and frozen into blocks three inches thick, and twelve by twenty-four inches in area.

PRACTICAL RECIPES.

GILDERS' COMPOSITION FOR FRAMES. — The composition at present in use is composed of best black glue, common resin, and linseed oil. Some use resin oil, others boiled linseed oil. Nearly every manufacturer has a little change in the proportions. It is a useful material for many other purposes, to which it might be applied were its mode of manufacture known. Take 10 lbs. of best black glue, boil it in the usual manner, but with very little water. It should be at least four times as thick as the glue used for general purposes. Take 6 lbs. of common resin, and pound to dust; add linseed oil, or resin oil, to form a thick paste with the dust; dissolve with heat, allow it to cool to about 212°, then add the hot glue; combine it well. Have sifted whiting prepared, and combine the whole as in making bread; form it into cakes, and allow it to cool; at any time by the application of steam or heat, this composition may be brought into use.

TO PREPARE PURE OXYGEN. — Prof. Boettger states that when a mixture is made of equal weights of the peroxides of lead and of barium, and dilute nitric acid of a strength of nine degrees Beaumé is poured thereon, a current of pure oxygen gas, free from ozone and antozone, is given off abundantly. This mixture of the two peroxides may be kept dry in a stoppered bottle for any length of time.

WHITE POLISH FOR LIGHT WOODS. — Take white (bleached) shellac, 3 oz.; white gum benzoin, 1 oz.; gum sandarac, ½oz.; spirits of wine or naphtha, 1 pint, in which to dissolve.

REFINED OIL. — Oil for fine mechanism is prepared by putting zinc and lead shavings, in equal parts, into good Florence olive-oil, and placing it in a cool place till the oil becomes colorless.

METEOROLOGICAL MONOPOLY.—The *Telegrapher* has the following good-natured hit at the pretensions of the holders of the Page patent: —

"Admirers of the sublime in nature will be sorry to learn that we are likely to be deprived of the pleasure of witnessing any thunder-storms during the ensuing year. The electrician of the Western Union Company, after a protracted investigation, has discovered that thunder and lightning result from the inductive action of short clouds upon long ones, and are therefore a direct infringement of the Page patent. It is understood that President Orton offered to make liberal arrangements with the Clerk of the Weather if he would come forward voluntarily and take out a license. The latter having neglected to do so, and the season for such exhibitions being near at hand, the Western Union Company now propose to charge a royalty of ten dollars per flash on chain and five dollars on sheet lightning. Ball lightning and the aurora borealis are exempt for the present, as the company's electrician has not yet fully decided whether they are covered by the claims of the patent. It is reported, however, that a temporary injunction will be obtained, restraining the defendant from giving any exhibitions until the electrician has concluded his investigations."

AN INFERNAL MACHINE. — A gigantic steam scoop, called "Beelzebub's Spoon," is dredging in Devil's Lake, Baraboo, Wis.

Agriculture.

ABOUT THE POTATO.

OUR common potato belongs botanically to a very suspicious order of plants, and it is well for the admirers of the tubers not to inquire very closely into its family relations. The knowledge that the potato is first cousin to such plants as tobacco, belladonna, henbane, nightshade, etc., all of them deadly narcotics, might trouble the sensitive nerves of some lovers of the delicious vegetable. Is the potato plant poisonous? Certainly it is. The stem, foliage, and fruit contain the same poisonous principles as henbane, and cannot be consumed as food without disastrous consequences. Fortunately the *underground branches* are free from injurious substances, if they are entirely covered with earth. But what is meant by underground branches? We mean the tubers themselves, for they are nothing but subterranean portions of the plant structure, and are not roots. A potato is a vegetable monstrosity, an abnormal production, which is extraordinary in every particular. The tuber is a branch of the plant which takes to the ground, and its growth becomes arrested and thickened, forming a knot or bunch which consists largely of pure starch. If a portion of this underground branch pushes its way out of the soil, the epidermis assumes a green color, and then it becomes, like the above-ground branches, poisonous. The *green* potatoes which are found growing half exposed to air and sunlight in our fields should be rejected, as they are totally unfit for human food. The potato has true leaf-buds, or scars (the parts called the *eyes*), and in this respect resembles the stem. We can cut out these eyes or leaf-buds, and from them propagate the plant, each eye growing and producing an independent structure. These facts should lead us to understand that the subterranean portions of plants are not always roots.

The potato in its early cultivation met with strange vicissitudes, and great opposition. The stern old Puritans opposed its cultivation, and denied its lawfulness as an article of food, because the plant was not mentioned in the Bible! Sir Walter Raleigh carried the plants to England from this country in 1586, and put them in his garden. His gardener thought the green potato apples were the potatoes, and expressed his disgust to his master at such products. He was told to pull up the weeds and throw them away. In doing so he found the true potatoes, more than a bushel in quantity, and he hurried back to Sir Walter in a very happy humor, to show him the sample and make known his discovery. So late as 1725 it was only cultivated in gardens in England and Scotland. During a period of more than one hundred and fifty years after Sir Walter introduced it into Ireland, it failed to rise superior to the prejudices of English cultivators. This is a singular history indeed.

A plant so nutritious, whose culture is adapted to almost every soil and climate, must be regarded as among the choicest gifts of Providence, and one that is destined to hold its place in the estimation of millions of people so long as time continues.

No plantyields so great an amount of nutriment from the same extent of soil as the banana. Humboldt estimated that it returns twenty times as much as the potato, and 133 times as much as wheat.

FARMERS' CERTIFICATES.

WE wish that farmers would reflect a moment before signing their names to certificates recommending fertilizers, agricultural implements, seeds, plants, etc. A great moral wrong is often committed in this regard, and evil is involved in it of no ordinary magnitude. Farmers who would be horrified at the idea of signing a note or a subscription paper, are easily persuaded to place their names to a document lauding some new fertilizer, or machine, which is a cheat, or entirely valueless. It is often done to get rid of importunity, or it is extorted by flattery, or by some gift or peculiar attentions which designing men know so well how to bestow. It is certain that in the history of new projects or new deceptions, whether connected with agriculture, medicine, invention, or art, nothing has ever been devised so worthless, that a multitude of names could not be procured recommending the imposture. Millions of dollars have been taken from the hard earnings of industrious, honest men through the powerful agency of such names. A fertilizer man leaves a bag of his stuff at the door of a farmer in the spring, desiring him to "try it," as the phrase is. It is applied to a few hills of potatoes, or corn, or vines, and if it does not positively kill the plants, the farmer will care but little about it, and the experiment be almost or quite forgotten. In the summer or early autumn the fertilizer man again makes his appearance, and this time he is provided with a written document highly recommending the powder, which he very politely requests the farmer to sign. A sense of obligation, or a desire to please, or the idea of having one's name in the newspapers and upon circulars, leads to the easy procurement of the name, and the enterprising manufacturer "laughs in his sleeve," and carries the document to the next "experimenter." He probably will sign it because his neighbor has done it, and so the names roll up, and the fraud is fully endorsed. This is no untruthful or fancy sketch of proceedings which are quite too common. It should be one of the most difficult things in the world to procure a name endorsing any substance or thing, and when a name is given it should be conscientiously, carefully considered, and there should be positive, known truth in every statement made.

THE MASSACHUSETTS AGRICULTURAL COLLEGE.

THE Eighth Annual Report of the Trustees of this institution has been published, and we have given it a pretty thorough examination. The practical working of our so-called Agricultural Colleges is worthy the attention of every friend of scientific husbandry, and we must not allow them to escape observation, and if need be criticism, as they are costing the people a great deal of money, and this money should not be squandered in any impracticable schemes or foolish experiments. We are gratified to be able to say that the condition of our own State institution, as shown in the Report before us, appears to be promising. As yet, comparatively little has been accomplished, but the plans of the future appear to be judicious, sensible, and correct in most particulars. There is a crowd of students connected with the College, more than the dormitories can accommodate, and we are glad to know that so many of our young men are anxious to learn the "farmer's trade." We expect to see them within the next ten years

in the fields, the hay-lofts, and manure-pits connected with our farms, with hoe, pitchfork, and shovel in hand, hard at work, regardless of sunshine, storms, or bad odors. President Clark appears to be the right man in the right place. He is energetic, practical, and entirely devoted to the interests of the College.

THE AGRICULTURAL RESOURCES OF FRANCE.

It is not often that professed politicians, when invited to address farmers, say anything that is in the least degree useful or profitable. They care more for the farmer's vote than they do for his crops, and their talk is usually that of the demagogue and selfish partisan. We presume a considerable number of our readers have heard of "Ben Butler." If the newspapers are to be relied upon, the gentleman has been, or is, a member of Congress, and during the last session made a "few remarks" in the House, now and then. He was invited last year to give the Annual Address before the Essex Agricultural Society, and strange as it may seem, he had not a word to say upon war or politics, but, with rare good sense, devoted the hour to a consideration of our agricultural resources in contrast with those of other nations, especially France. We are led to present to our readers copious extracts from this address, as we are convinced that the facts will be new to many of them, and may serve to dissipate the idea that we are the greatest agricultural nation in the world, as well as to show that "poor France" is not so very poor after all, if the demon of war could be banished from her soil:—

Let us direct our attention to a land where all eyes are now turned for a wholly other and different reason. Let us examine the agriculture of France, and compare its productions with our own, and compare the habits of its people, as farmers, with ours, and see, if we can, what it is that tends to show differences in their favor. Here we may find facts which will teach the statesman and farmer both, lessons in agriculture, and quite possibly facts which will arouse the attention, as surprising in themselves and containing not a little of rebuke to our general self-gratulation. One of our vices as Americans is self-gratulation, a little vain-gloriousness, a little boast. We speak of our teeming West. We speak flippantly of our capability of supplying all the world with breadstuffs. True, we have the capability so to do; but it is equally lamentably true that we do not do it. The boastful Western man upon his prairies or the Californian upon his ranche will, not a little astonished, learn the fact that the Empire of France, with not so much area as the State of Texas, raises more wheat, in quantity, than the United States of America all told, reckoning from Alaska to Florida and from Texas to Maine; the area of France being only 207,480 square miles, or 132 million acres, while Texas contains 237,321 square miles, or 154 million acres. And yet the product of wheat in France, in the year 1868, was 350 million bushels; the total product of wheat in the United States for the same year was only about 240 million.

So far from our supplying the markets of the world with wheat, in the year 1867 we sent to England only four million hundred weight of wheat, or about nine million of dollars in value, while France exported to England eleven million dollars' worth of butter alone, to spread on the bread made from our wheat, or, to speak less lightly, France sent more value in butter to England than we did all kinds of breadstuffs.

Again, to go back to the year 1860, where only we can get accurate statistics of the products of the United States and the products of France, let me call your attention to the following remarkable but reliable statistics of French agriculture. France then produced 230 million bushels of oats against our 170 million: 70 million bushels of rye against our 20 million; 60 million bushels of barley against our 12 million; and 32 million bushels of buckwheat against our 12 million. Nor was she without the products of grazing and pasture land, which are supposed to be the necessity requiring our extended farms. She had 4 million horses and mules against our 4 million and a quarter: 12 million of neat cattle against our 13 million; 30 million of sheep against our 24 million, and 6 million of swine against our 16 million.

As an example of what may be the profits of the smaller industries of farming, which, by the farmers of the United States, are reckoned almost valueless, it is an astonishing fact that in the year 1866 France exported as much in value of eggs to England alone as we exported of bacon and hams, one of our chief exports of provisions in 1868, to all the world; that is to say, in round numbers, rising of five million of dollars, while we exported eggs last year to the paltry number of 412 dozen.

No man who has not had these figures brought to his consideration and who has not examined the agricultural productions of France, both in variety and amount, can believe that the 38 million of her inhabitants on a territory so small as to give only three and a half acres to an inhabitant, could vie, in agricultural productions, of all that goes to make up the necessaries of living and national wealth, save cotton and tobacco, with a nation like ours of about the same number of inhabitants, whose territory gives more than 50 acres to each inhabitant, or nearly seventeen times as much land for cultivation, and from this estimate we exclude Alaska, of which none know the extent save the walrus and polar bears. Of course, a very large portion of our lands, say three fourths, are substantially uninhabited; but these are always reckoned when we make up our national resources.

Nor is the common idea a true one that the people of France are poor, or that our people are drawn away from farming into other and more profitable occupation, so that France does not more than equal us in the value and amount of her industries — all her industries as compared with ours; for in the year 1868 her imports amounted to 679 million, and her exports to 581 million, while in the same period the imports of the United States were only 381 million and the exports were 441 million, of which exportation 72 million were gold and silver and 163 million of unmanufactured cotton, neither of which, to any extent, was exported by France, leaving only 206 million as the product of our agricultural and manufacturing industry for export, after what is consumed by our people, against 581 million, which is the surplus of her agricultural and manufacturing industry exported after maintaining her own people. And although we boast of our cotton and tobacco as sources of wealth, yet she has her wines, brandies and sugars, of which latter France exported in 1868, six million dollars, and we imported sixty millions.

The common idea in this country that wealth is not diffused in France as with us, but is only in the hands of a few rich nobles, is another mistake quite as illusory as any of the misunderstandings of the agricultural and industrial condition of our ancient ally. While the national debt of France at the beginning of the present year was almost precisely the same as ours — being 2,700 million; yet, instead of being as ours is, 1,500 million owed to foreigners, to say nothing of state and county debts, which are things unheard of in the departments of France, it is divided among and held by more than *eleven hundred thousand Frenchmen*, giving a share of about 2,500 dollars to each. The actual diffusion of wealth among the middling and industrial classes is evident because when a loan of 90 million of dollars was offered by the Emperor to the people, an actual subscription of 3,152 million, or more than 35 times the sum asked for, was made by 781 thousand different persons (all Frenchmen, and generally in small sums because the providence of their government, differing from ours, gives to the man who desires to invest ten dollars in the national fund the preference over him who desires to invest ten million, the small subscription being first received, and first filled.

It may be interesting, although not exactly in consonance with the purpose we have in this analysis to compare the division of the debt of France among the people, showing the diffusion of wealth in the middling classes, with the national debt of Great Britain. Her debt amounts to 3,800 million, which is held by 126 thousand persons only, giving an average share of 30 thousand dollars to each individual as against less than one tenth as much to each holder of the French debt.

Nor are the French people burdened with taxation more than we are. They have nothing of the taxation known with us as State taxes, but their entire taxation is a national one, and amounted, with the revenues, which are another form of taxation in the aggregate, in the year 1868, to 403 million of dollars, while our taxation and revenues for the same year, paid to the national government alone, was 405 millions. But it will be observed that this taxation, while nominally about the same as ours, yet being with us based on a much less product of trade and industry than in France — almost 50 per cent. less in fact — is really a taxation nearly 50 per cent. greater on the industry of this country than is imposed upon the industries of the French people.

But another and more certain test of the distribution of wealth in France is seen in this: the population being divided into 9 millions of families, allowing four to the family, which is nearly the ratio, 1 million of those families, or 4 million of people, are in easy circumstances, that is, able to live without work or business. Of the remaining 8 million, which may be said to be composed of the industrial and working classes, 3 million only are inhabitants of the towns. That is, of the whole population, two fifths of the people in France live in the cities, and three fifths live in the country. This gives a very surprising result as compared with England, where four fifths of the whole people live in town and one fifth only in the country. We have yet no data with which I am acquainted, to make a like comparison with this country.

All property is then very equally distributed among the bulk of the population. There are six million of houses in France, the greater part of them cottages with small plots of land. Nearly the whole of this number are small freeholds belonging to their occupants. In other words, more than two thirds of the entire population own their own houses.

After hearing these statistics, the question, I have no doubt, arises to the lips of each one of my auditors, as it came to me, — how are these very great results possible? What is the secret? This may be told in a word. It is the thorough cultivation of the soil. Of her 132 million of acres, 64 million are arable; 12 millions only are in meadows, or, as we say, fields and grass; 5 million in vineyards; $1\frac{1}{2}$ millions in orchards and gardens; 2 million in miscellaneous crops; 20 million in wood and forest; a half million in ponds: 20 million only may be called heath or waste lands, the remainder being for roads, public squares, canals and pleasure grounds — about 7 millions of acres. Thus it will appear that two thirds of the entire area of France is under actual cultivation every year.

Boston Journal of Chemistry.

WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, JUNE 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

END OF VOLUME FIFTH.

THE present number of the JOURNAL completes Vol. V., and the next issue commences a new year. It is perhaps a slight disadvantage to begin the Journal year in July, but it would cause confusion in our arrangement of volumes to change to January, and so it will continue as it has been. As we now receive subscriptions to commence at any time during the year, it may be well to remind our friends that we can supply full volumes or separate numbers of the past two years, and shall be happy to execute their orders promptly. Every number of the JOURNAL is *electrotyped*, and copies can be supplied to any extent. In our next number, under the heading of "How We Stand," we shall present some statements regarding the success and the future prospects of the JOURNAL.

The INDEX to Vol. V., will be sent with this number to all who have paid for the volume. It will be sent, postpaid, to any address on receipt of *ten cents*. This Index includes not only the headings given in our Table of Contents from month to month, but all the sub-headings that have appeared under "Household Recipes," "Memoranda in the Arts," "Editorial Notes," "Medical Memoranda," "Valuable Formulæ," etc., etc. The latter are far more numerous than the former, and will enable one to find readily any item he seeks. A glance at the Index will show what a multiplicity and variety of topics are discussed in a single volume of the JOURNAL, and what a *popular cyclopædia* of scientific and other information we furnish for *one dollar*.

LEAD AND GALVANIZED IRON WATER-PIPES.

A NOTE appeared in the *Boston Medical and Surgical Journal*, a few weeks ago, signed by Dr. Winsor, of Winchester, in which he stated that we had recommended the use of lead water-pipes in a report made to the Spot Pond Water Board of Melrose. He also took occasion to reassert his opinion of the safety of the galvanized iron pipes. The following communication was published in the *B. M. and S. Journal*, of May 4th, as a reply to his statements :—

MESSRS. EDITORS,—The communication of Dr. Winsor, found in your JOURNAL of April 13, conveys, whether intended or not, an unfair and erroneous impression, and I hope you will allow me space to correct it. Whatever construction may be put upon the language of the Spot Pond Water Commissioners as presented in their circular, it is certain they did not intend to recommend unqualifiedly or "virtually" lead pipes for water conduction. They speak of them as "comparatively safe," that is, compared with the "galvanized" iron pipes, and express a desire that the citizens of Melrose would remove such from their premises, even if lead has to be substituted. The chemists employed by the Board (J. R. Nichols & Co.) do not in the report presented in the circular, "virtually" recommend lead pipes, as stated by Dr. Winsor. They intended to convey the idea that, as the result of careful experiments made upon Spot Pond water in connection with the two kinds of pipes, lead is less objectionable than galvanized iron. They state that under "ordinary conditions" lead is safe to conduct Spot Pond water, and this is true of the waters of most New England ponds. The waters of these open reservoirs among the hills are quite free from chlorides and nitrates, and generally hold in solution sufficient carbonic acid to change soluble oxides into insoluble carbonates; therefore the waters exert a protective influence by the formation of an insoluble coating of carbonate of lead upon the interior of the pipes. If this coating was not liable to be interfered with by local agencies, lead pipes would be "virtually" safe to conduct water from these ponds, and I should not hesitate to recommend them. But so long as this liability exists, however small the risk, they must be regarded as dangerous.

For a period of more than twenty years, the writer has made frequent and extended experiments upon waters brought in contact with lead, and these waters have been taken from ponds and open reservoirs in nearly all the New England and Northern States. In 1857, fourteen years ago, he published a paper in this JOURNAL upon "local decomposition in lead aqueduct pipes," in which the results of a series of experiments upon Cochituate water were presented in detail. They coincided with those of Prof. Horsford and Dr. C. T. Jackson, the able chemists employed by the City Water Board, so far as relates to the general protective influence of the water, but it was shown that there was danger from local decomposition in service-pipes, and lead was detected in the water flowing into dwellings in various parts of the city. It was proved that local disturbances arose from changes in the electrical condition of the pipes, twisted and bent by plumbers when placed in position; also that organic matters—mud, leaves, and other vegetable *débris*—were capable of dissolving the coating of carbonate of lead and rendering pipes unsafe. In this communication, which may be seen by consulting files, the writer was emphatic in condemning lead pipes, and in no subsequent printed or verbal communication has he actually or "virtually" recommended them.

As regards the statements of Dr. Winsor concerning the safety of the "galvanized" iron pipes, which have appeared in this JOURNAL in the form of Reports, etc., little need be said beyond the bare expression of regret that such communications should have appeared at all. The question of the influence of zinc-impregnated water upon the health of individuals and families is of the gravest importance, and should not be discussed by one who has no experimental results or personal observations to offer, and who is unable to quote from a single credible or respectable authority. If Dr. Winsor was *required* to write or "report" on this subject, he could have given to his paper some value by consulting proper books and files of scientific journals, and presenting the results of experiments and observations made by others. If he had even opened the U. S. Dispensatory, a book presumed to be found in every doctor's library, he would have learned that the salts of zinc were regarded as poisonous many years ago. Prof. Bache says :—"The compounds of zinc *are poisonous*. The oxide of zinc, used in painting as a substitute for white lead, is said to be capable of producing a colic resembling that caused by lead and called *zinc colic*. It attacks workmen engaged in packing it in barrels, and yields to the remedies appropriate to the treatment of lead colic."

The old *Chemical Gazette* published an article in September, 1850, upon zinc poisoning, in which facts are presented of a startling character. The experiments of Dr. Witherbee and others with the salts of the metal upon animals, prove the oxide and chloride to be fully as dangerous as any of those of lead. The sad and fatal effects which in England followed from the use of milk and butter which had been in contact with zinc vessels, are significant facts which ought not to pass unheeded by careful, competent physicians. Disregarding the allusions made by Dr. Winsor to physicians who have with great care reported cases of zinc poisoning in this vicinity and in the Western States, I will simply state that several well-marked cases of zinc poisoning have come under my observation during the past year, and no one can reasonably doubt that a considerable number have suffered to a greater or less extent from the oxide and perhaps chloride of zinc, brought to them in water which passes through the so-called "galvanized" iron pipes. To me it is a matter wholly incomprehensible that a physician in respectable standing should be willing to state, over his own signature, that the filthy, unscientific zinc-washed pipes are proper for water conduction, that "no safer available material for water pipes than galvanized iron is known to us." And this is said after "virtually" admitting that all the zinc is dissolved from the pipes by the water and disappears in a few weeks, and that the carbonate and oxide of the metal are largely found in the water employed in the culinary departments of dwellings.

JAS. R. NICHOLS, M. D.

REPORT OF THE SALEM WATER BOARD.

THE good people of the city of Salem who take water from Wenham Lake, ought to feel grateful to the gentlemen of their Water Board for the assurances conveyed in their last Report, that "the galvanized iron pipes are the best service pipes in use, and the *citizens need have no fears of poisonous matter in their water.*" It is a pity that there should be any drawback upon these comforting assurances. We are afraid the intelligent water takers of that ancient city may be in a slight measure disturbed by the very next remark of "the Board." They say, "When the pipes are new (the galvanized), or if the water has been standing in them over night, *it may be well to draw off a pailful or two of the water before using*, but if the pipes are in *constant use* there is not the slightest danger of any poison in the water." As aqueduct water is very apt to "stand" in service pipes "over night," and as the kitchen Bridgets and Maries are apt to forget to "draw off" a bucketful or two every morning, it is very possible that some of the citizens may take, in their tea or coffee, a little of this water which the Board advises, *for some reason*, to be *thrown away*. As, however, the citizens are further told that "constant use" of the pipes avoids the "slightest danger of *poison*," they may conclude to open their faucets and let the water run continuously. In no other way can the pipes be in "constant use," and in no other way, it is to be inferred from the statements of the gentlemen, can there be safety in the use of the "perfectly safe" galvanized pipes. It is evident the Water Board are a little "confused" in their views, but this is not the worst of it; the statements of their consulting chemists are unfortunately "very obscure." They state, as quoted in the Report, that they "experimented with and analyzed the water after it had stood 15 hours in the galvanized iron pipe, and the water was *perfectly clear, and con-*

tained a sediment in the bottom." Indeed! water that lets fall "a sediment" may be "perfectly clear," but there is a strong suspicion that there has been a time when it was not so "clear." These chemists go on to state that they "found this sediment to be zinc," but there was "none in the water." Why, then, do they not recommend the water takers to draw the water and "let it settle" before using? This would be as sensible and practicable a way to get rid of the poison, as to draw and throw it away, as recommended by the Water Board. We are not acquainted with the chemical gentlemen who make this luminous Report, but it is stated they are from Philadelphia, a city long famous for its "lawyers," and for its men of science also. There are a great many cultivated and sagacious people in Salem who are fully competent to appreciate this Report, and further comment is unnecessary.

LUBRICATING OILS AND INSURANCE.

The article upon "Spontaneous Combustion" in our March number appears to have attracted considerable attention in various quarters, having been copied in full or in part by many scientific and other journals. That spicy little sheet, *The Oil Monthly*, after quoting that portion which suggests that "the introduction of coal oils for lubrication of machinery has very materially reduced the number of fires from spontaneous combustion, owing to the fact that the coal oils *do not absorb oxygen*," and that insurance companies should recognize this fact in fixing their rates for mill property, comments upon it as follows: —

"That all underwriters should count well their risks, and refuse to insure where dangerous articles are kept, is certainly commendable; but that they should prohibit the use of paraffine or coal oils in cotton and woollen mills, is an indication of a prejudice bordering on perversity. Lard, whale, and even linseed oils are not objected to, but any mineral oil is regarded as dangerous. While lard and whale oil *can* produce spontaneous combustion, and linseed oil is particularly liable to it, the very nature of the mineral oils is cooling; for not being capable of absorbing oxygen, they are absolutely proof against self-ignition. In the manufacture of the hydro-carbon oils, all the volatile and burning properties are taken off before the remaining oil becomes heavy, or is worthy of the name of a lubricator. This heavy oil is nothing but a *grease*, and will burn no easier than butter or lard. A red-hot iron immersed in it would have no more effect than if dipped in so much water. Nothing but an intense heat sufficient to vaporize it will cause it to burn."

CONCERNING "GASOLINE."

Respectable journals are not unfrequently rash in the "puffs" they give the manufacturers of bad kerosene, under its many *aliases* of "gasoline," "safety oil," "sunlight oil," etc.; and we wish that they were all as ready to retract the hasty and indiscreet commendation as the *American Builder*, of Chicago, has been in a recent instance. That excellent journal is so rarely at fault that it will not suffer in reputation for the frank confession made in the following article from its May number: —

"'The light is clear, steady, and much whiter than that produced from kerosene, burns with no perceptible odor, and is unincumbered with a chimney, that ever-breaking nuisance which accompanies an ordinary lamp.

"'Good gasoline is as safe as kerosene, is cheaper, and gives a better light.'

"So read a 'local notice' in the last issue of this magazine, but the statement made in the lower paragraph is hereby retracted, with an apology to the public. We wrote candidly, and thought we were telling the truth, but have since had reason to believe that gasoline is not so safe as, in fact, almost anything else. We tried a lamp, and for a week all went well, and the above notice was written; but since then there has been an explosion. Nobody was hurt, but the demoralization was extreme. The lamp contracted a habit of lighting, much in the manner a newly arrived Irishman described the sun as setting in this country, after he had heard the evening gun fired, — 'wid a bang.' But this was considered only one of the eccentricities of genius — of the inventor — and the lamp still remained in favor, for it certainly did give a clear light. But the crisis came at last. On a recent memorable occasion the lamp, somehow, would not burn well for two or three hours, but in a single moment it made up a good average flame for the entire evening. The flame suddenly shot up to the height of a yard, and burned blue and fiercely. Frontiers were rectified, and the room vacated rapidly. Then followed an earthquake, and now the lamp has a permanent physical deformity. It is for sale.

"The conclusion reached by the experiment is, that gasoline may be safe for a week, but no longer. At least, there's no depending upon it after the expiration of this time, and we cheerfully subscribe to it, as something no family should be without, where there is more of a family than the parents can honestly support."

COFFEE AND TEA.

One of our best physicians sends us the following note: —

"I am extremely fond of a good cup of coffee, and wish to add my testimony as to the truth of the article on this subject in your March number.

"Twenty years ago, I purchased in Paris a small filtrating coffee-pot. For a long time I used the coffee ground as coarsely as it is usually sold in the shops. Although procuring the best berries possible, I did not uniformly succeed in obtaining at the breakfast table a first-rate beverage. I consulted many wiseacres, some of whom said that the water used should be hotter, others that the coffee should be first soaked in cold water, etc., etc. By mere accident one day I happened to have the coffee *re-ground* to the fineness of snuff. Herein lay the mystery. I have never since failed to obtain a strong, full-flavored beverage, and that, too, without using so large a quantity of coffee."

A correspondent of the *Independent*, travelling in Sweden, was intensely delighted with the coffee served on the steamboats and hotels. "At Upsala," he writes, "we determined to find out how they made such perfect coffee as we had just drank, and stepped into the neat little kitchen of the little hotel, and this was the report: Take any kind of coffee-pot or urn, and suspend a bag made of felt or very heavy flannel, so long that it reaches the bottom, bound on a wire just fitting the top; put in the fresh ground, pure coffee, and pour on freshly boiled water. The fluid filters through the bag, and may be used at once; needs no settling, and retains all the aroma. The advantage of this over the ordinary filter is its economy, as the coffee stands and soaks out the strength, instead of merely letting the water pass through it."

A French chemist asserts that if tea be ground like coffee before hot water is poured upon it, it will yield nearly double the amount of its exhilarating qualities. Another writer says: "If you put a piece of lump sugar, the size of a walnut, into a teapot, you will make the tea infuse in half the time." Persons who have tried this last experiment say that the result is satisfactory.

EDITORIAL NOTES.

Preserved Meat. — In 1866, the whole value of preserved meat brought from Australia to England was only £321. In 1870, the importations amounted to £200,000, and it is estimated that this year they will be at least doubled. To introduce the article to the lower classes, cheap eating-houses have been opened in London, Manchester, Liverpool, and other places, where the meat is dressed in a variety of ways by good cooks and sold in penny dinners. At one of these establishments a steam cooking apparatus has just been added, which will provide for 10,000 persons at a time. The proprietor proposes to send out hot penny dinners to factories and other places where large numbers are congregated, and the system is likely to work well.

Most of the patent methods of preserving the meat, however, have proved to be failures. *Land and Water* remarks that "none seem really to have answered as yet, except the old-fashioned system of salting and packing in hermetically sealed cans, and the new extract system invented by Liebig." In this country, Lyman's process promises to be perfectly successful. Messrs. Clapp, Bridgman, & Co., of Houston, Texas, are now putting up large quantities of "concentrated roast beef" by this method. As soon as the animal is killed, the meat is cut from the bone, put into a vacuum chamber in which it is cooled by its own evaporation down to about 40°, and then placed in an oven, about twelve feet high, where it remains exposed to a current of pure warm air at a temperature of from 160° to 180° for three or four hours. The meat is laid upon shelves of iron rods, one above another, and is carried slowly by an endless chain from the top to the bottom of the oven. The juices from the upper shelves drip upon the meat on the lower ones, and by the time it reaches the bottom it has ceased to drip, and is thoroughly cooked, without having lost a particle of its nutritious matter. It is then chopped up fine, pressed into cans, and sealed up. The cans are afterwards heated in a bath of boiling water, pricked so as to let out the air and steam, sealed up again, and kept hot for three or four hours more, in order to combine any free oxygen that may possibly remain in the cans. The whole process is continuous, and in ten hours after the animal is killed the beef is packed and sealed up. A thousand pounds of beef, including the bone, furnish one third the weight of the concentrated meat, which is sold in the markets at twenty-five cents a pound. It is likely to become a popular article of diet, especially as a substitute for the ordinary salted beef, than which it is both cheaper and more nutritious.

Popular Lectures on Science. — In referring to the penny lectures on science, at Manchester, England, we asked the question, "When shall we have something of the kind in this country?" Our correspondent, C. S., reminds us of the Lowell Lectures in Boston, and other similar courses which do not cost even the penny, being free to the public. Of course we did not forget the existence of the Lowell Institute, and the other admirable institutions of the kind which are now to be found in New York, Baltimore, and other of our cities. But these as yet are only exceptional instances, and we meant merely to express the hope that in some "good time coming" they may be the rule rather than the exception. We believe that in providing for popular instruction in science, not only by lectures, but by other educational agencies (of which the South Kensington Museum is the most notable example) and by cheap literature, England is considerably in advance of this country, though we are beginning to emulate her example. We shall speak of the subject more at length hereafter.

The Theory of the Bunsen Flame. — As we stated, a year or more ago, in an article on the luminosity of flame, Frankland's investigations throw

some doubt upon the commonly accepted theory that the light is solely due to incandescent carbon, and that the non-luminosity of the flame of the Bunsen burner is caused by the perfect combustion of the coal-gas; the particles of carbon being burned up at once instead of remaining for a moment in a white-hot state before the oxygen can get at them. Some recent experiments by Herr Knapp appear to prove that this latter explanation cannot be the correct one. He finds that if instead of allowing air to mix with the coal-gas in the Bunsen burner, a sufficiently strong stream of nitrogen, hydrochloric acid, or carbonic acid gas, no one of which can act as a supporter of combustion, be passed into the flame, the latter becomes perfectly non-luminous. Probably this is in great part due to the reduction of temperature and pressure in the flame consequent on the introduction of the above gases.

ATOMS.

A German pharmacist recommends chloroform for rendering cod-liver oil palatable; 10 drops to 3½ ounces of oil being sufficient. — There are now about 250 postmistresses in the country, and the number is rapidly increasing. — Coniine, the alkaloid found in the poison hemlock (*Conium maculatum*), has been made artificially, by Schiff; and we may look soon to see morphine and quinine produced in the laboratory. — The total value of machinery, agricultural implements, etc., exported from Great Britain, last year, amounted to £5,337,774, or over twenty-six millions of dollars; rather more than one half of the amount being for steam-engines. — The cotton-seed product of the Mississippi Valley would make forty million dollars' worth of oil. — The street railways of Philadelphia carried last year over fifty-five millions of passengers, of whom but one was killed and four injured. — In 1870 more than ten tons of chloral were imported into England from Germany; almost enough, one would suppose, to put the whole island asleep. — Pure *carotine*, a tasteless and inodorous yellow compound, obtained from carrots by slicing, drying, and treating with bisulphide of carbon, is recommended as a substitute for annatto in the coloring of butter. — Pencil and crayon drawings may be fixed on paper, by washing the back of the sheet with a moderately strong solution of bleached shellac in alcohol. — It is said that a little coarsely cut gentian root well masticated (the saliva being swallowed), taken after each meal, will soon cure one of all desire for tobacco-chewing. — If you want some of the best English scientific journals at half the price usually charged for them in this country, look at our clubbing list. — The first crop of potatoes ever raised in England was grown at Formby, on the Lancashire coast, by a native of that village, who had sailed with Sir Walter Raleigh. — The *American Journal of Microscopy* is a new monthly "devoted to the elucidation of scientific and popular microscopy," edited by E. M. Hale, M. D., and published at Chicago, for two dollars a year. — Certain pious Hindus, anxious for the spiritual welfare of their young countrymen in England, have resolved to build a Hindu temple in London, and have subscribed a lac of rupees for the purpose; so there will be no lack of money to carry out the plan. — An edition of the English Statutes, accompanied with explanatory comments, has been published in London, which is sold for *one penny*. — Of eighty "freshmen" in the Michigan Agricultural College, sixty are the sons of farmers. — A Scotchman lately bought ten thousand acres of land in the Fiji Islands, for sixpence (twelve cents) an acre. — An acre of land in London was recently sold for $3,600,000. — About 850,000 tons of coal are used annually in London to make some 8,000 *million* cubic feet of gas, and the "little bill" for the same amounts to more than eight million dollars. — Some of the leading Southern journals are calling the attention of French immigrants to the attractions of that section of the country. — The city of Cleveland, Ohio, is excavating a tunnel under Lake Erie, a mile and a half from the shore, for the purpose of procuring a supply of pure water.

LITERARY NOTES.

The Harpers have just published the *ninth* enlarged and revised edition of Prof. Martyn Paine's *Institutes of Medicine*. When a large and elaborate work like this has reached a ninth edition, it has evidently come to be regarded as a medical classic, and its latest revision needs no special commendation from us. The book has been well called "a library of philosophical and practical medicine," for it contains the learning and labor that would ordinarily be expanded into many volumes. "Its strong points are a broad and thorough treatment of the whole science of physiology, pathology, and therapeutics; a sturdy conviction of the soundness of its positions; a clear understanding of the opposing theories; and a vigorous, classic, concise, and unflinching style of writing."

The Harpers are publishing a capital series under the title of "Science for the Young," by Jacob Abbott. The first volume, on *Heat*, is now ready. They have also in press Shakespeare's *Tempest*, with notes by W. J. Rolfe, A. M., to be uniform with his edition of *The Merchant of Venice*.

Messrs. Lippincott & Co. have issued a new and improved edition of Bourne's *Handbook of the Steam-Engine*, which has an established reputation as the standard work on the subject. The introductory chapters on "the arithmetic of the steam-engine," and on "the mechanical principles of the steam-engine," fill nearly 200 pages, and form a good elementary treatise on Mechanics; and the chapter on "the theory of the steam-engine" is an excellent outline of the physics of Heat. The remainder of the work is devoted to the practical construction and management of the various kinds of steam-engines, and is exhaustive on these subjects.

Mr. Henry C. Lea, of Philadelphia, has reprinted the revised edition of Professor Attfield's *Chemistry*, "a manual on the general principles of the science, and their applications to medicine and pharmacy." The work holds a high rank in England, and as a handbook for the medical student and the pharmacist we know of nothing better in English. This edition adopts the new notation, and the partially reformed nomenclature which gives us *mercuric chloride* and *mercurous chloride*, *ferric* and *ferrous* salts, etc., but *nitrate of potassium*, etc. (not *potassic nitrate*), instead of the old *nitrate of potassa*. This, as the author says, is "a step in the direction of simplicity and consistency," but we wonder that those who have courage to take this step should hesitate to take the next, and thus to make *all* the names uniform and consistent.

We intended, last month, to speak of the *Annual of Scientific Discovery for* 1871, published by Messrs. Gould and Lincoln, of Boston. The volume is edited by Prof. Trowbridge, of Harvard College, and Prof. Nichols, of the Institute of Technology, and the work is in the main very well done. The introductory sketch of the progress of science for 1870 is excellent, but even there we note some awkward misprints, as "*presence* of the confined gas" for "*pressure*," etc.

Travellers about to start for Europe should not fail to read Curtis Guild's *Over the Ocean*, recently published by Messrs. Lee & Shepard. It is like a guide-book in the minuteness of its details, and yet it is very pleasant reading, which a guide-book is *not*. The reason is that it tells you the story as a friend would *talk* it to you when just returned from his tour, and eager to make you a sharer in all that he had enjoyed, while the guide-book tells it in the parrot style of the professional cicerones that beset one at every step in foreign lands. The majority of travellers are at the mercy of these fearful bores, because they do not prepare themselves for the trip in advance by reading good books of travel written by those who have been over the same ground. Besides this book of Mr. Guild's, we especially commend to friends who are going to Europe this summer *Old England*, by Prof. Hoppin, published by Hurd and Houghton, a year or two ago. There is nothing better worth seeing in that country than the old cathedrals, and you will enjoy them all the more for the companionship of so genial and sympathetic a guide. Rev. Dr. Peabody's *Reminiscences of European Travel* is another book that you should read before you go, and Gilbert Haven's *Pilgrim's Wallet* is another. The two latter together cover about all the ground that one can go over in a summer vacation in Europe. We might mention other books if we had the space, but the above are specially to be commended. In the way of a *Guide-book*, we have nothing as yet in a single volume that is better than Harper's. The maps and plans of cities in the last issue are a valuable addition.

Messrs. Hurd & Houghton have reprinted from the Edinburgh edition J. C. Shairp's *Culture and Religion*, a book which no man who has any claim to the one, or any interest in the other, should fail to read.

Wonders of the Heavens, from the French of Flammarion, translated by Mrs. Lockyer, is the last issue in the "Library of Wonders." The translation is not quite satisfactory, but the book is a good popular presentation of the leading facts in astronomy.

The second number of the *Memoirs of the Peabody Academy of Science* (Salem, Mass.), containing "Embryological Studies on Diplax, Perithemis, and the Thysanurous Genus Isotoma," by A. S. Packard, Jr., has been issued in very handsome style by the Academy. We have received also the *Second and Third Annual Reports* of the Trustees, which make a very creditable exhibit of the work done in the past two years by this excellent scientific association.

Prof. G. H. Cook, the State Geologist of New Jersey, has sent us his *Annual Report for* 1870, which contains much interesting matter, especially on the subject of marshes and reclaimed lands, and on the analysis of the soils of the State.

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

The American Journal of Science and Arts, for May, contains articles on the Solar Corona, by Prof. Young; on the supposed Legs of the Trilobite, by Prof. Dana; on some new Fossil Serpents, by O. C. Marsh; on the Estimation of Phosphoric Acid, by C. E. Munroe, of the Lawrence Scientific School; Calorimetric Investigations, by Prof. Bunsen; on the Geology of the Delta, and the Mudlumps of the Passes of the Mississippi, by E. W. Hilgard; with much other valuable matter.

The Journal of the Franklin Institute has fourteen pages filled with the editorial "Items and Novelties," an interesting miscellany, which is an admirable feature of this magazine; Editorial Correspondence on the Suez Canal; several valuable articles under the head of "Civil and Mechanical Engineering," and as many more under "Mechanics, Physics, and Chemistry;" with Bibliographical Notices, etc., etc.

The New York Medical Journal gives in full Prof. Lente's Oration on the Objects and Aims of Medical Science, and the Relations existing between the Medical Profession and the Public; an article on Hypodermic Injection, by Dr. T. J. Gallaher; one by Dr. G. M. Smith on Diabetes; with Proceedings of Societies, Miscellaneous and Scientific Notes, etc., etc.

The American Practitioner has the following Original Communications: Will Quinine Originate Uterine Contractions? by L. A. Sayre, M. D.; Observations on the Use of Mercury, by A. P. Merrill, M. D.; Iodine Inhalations in Diphtheria, by G. H. Eyster, M. D.; Sudden Death of an Applicant for Life Insurance, by S. M. Bemiss, M. D: Foreign Correspondence — From London, by R. O. C.; etc., etc.

The Oregon Medical and Surgical Reporter enters upon its second year as a quarterly instead of a monthly, and appears in enlarged and improved form.

The Boston Medical and Surgical Journal, of May 11, publishes Dr. Carpenter's Address on "Quackery in the Regular Profession," delivered before the Bristol North Medical Society, at Pawtucket, R. I.

The Nashville Journal of Medicine and Surgery, for May, appears promptly (which is a rare virtue with a medical magazine) and is an excellent number.

ANSWERS TO CORRESPONDENTS.

☞ Questions pertaining to *all departments of the paper* — home science, arts, agriculture, medicine, etc. — will be answered under this head, but *only when the subject is one of general interest to our readers*.

H. M., Brooklyn, N. Y. — A message does *not* make any perceptible sound in passing over a telegraph wire. The sounds popularly supposed to be made by the electric fluid are due to the wind blowing through or over the insulators, etc.

U. U., Springfield, Mass. — Our correspondent says that the scientific association in S. did not endorse the Cardiff giant as "a genuine antique," though some of its members argued that "fossils of like character might be in existence." We saw in a Springfield paper some certificates signed by certain officers of the association *as* its officers, and naturally supposed that they represented the association. We see that the "giant" is still on his travels in the Connecticut Valley, and that the local papers are "puffing" him in the old style. It has been stated on good authority that tool-marks have been distinguished on his body, and that they are evidently made by tools of modern invention. If one had any doubts on the point, this would prove that he is neither a "petrification" nor a work of ancient art.

J. B. C., Concord, N. H. — Mivart's "Genesis of Species" has been reprinted by the Appletons of New York, and they have also published the revised edition of Darwin's "Origin of Species."

L. A., Mound City, Kansas. — There is no remedy for perspiring under the arms, and no way of preventing the perspiration from changing the color of the dress, if it comes in contact with it. A lining of oiled silk under the arms often serves as a sufficient protection to the dress.

L. G. D., Ann Arbor, Mich. — The five-dollar microscope advertised by us admits of *four* different powers, and is really an excellent instrument for the price. It will "show eels in vinegar" (that is, if they are there) and may be used for the other purposes you mention, none of which require a powerful or costly microscope.

Flushing, N. Y. — An envelope from this post office comes to us with $1.00 enclosed, but no writing to show who sends it. We have quite a list of subscribers in Flushing, and do not know to whom the credit is due.

D. R. Smith sends us $1.00 for the Journal, but fails to give his address. Hence we are unable to credit the amount, or to attend to the other business mentioned in his letter.

Medicine.

OBSCURE SOURCES OF DISEASE.

NEARLY ten years since we published the following article upon obscure sources of disease, and the importance of the subject leads us to present it again for the benefit of our readers. There can be no question that the use of the galvanized iron pipes for the conveyance of water to dwellings is causing illness which physicians are unable to account for, not knowing the nature or dangerous character of the pipes. It is the duty of physicians to inquire closely into the character of water used in families, and the sanitary condition of dwellings, before deciding as to the nature or cause of diseases which they may be called to treat. These are points too much neglected by medical men both in city and country: —

There are many instances of disease brought to the notice of physicians which are exceedingly perplexing in their character, and the sources of which are very imperfectly understood. They belong to a class outside of, and distinct from, the usual forms of disease resulting from constitutional idiosyncrasies, or accidental causes, within the knowledge of the patient or medical attendant. The obscurity of their origin, and persistence under treatment, render them peculiarly trying to the patient and the skill of those who have them in charge, and after the trial of the usual remedies without effect, the patients are sent into the country or to the sea-shore, as the case may be, with the expectation that a change of air or residence may prove beneficial.

We cannot, in a majority of cases, regard these affections as altogether imaginary, or as resulting from some casual derangement of the nervous system; they are instances of true disease, and should be studied with the view of bringing to light the hidden source from whence they originate. I am led to believe that a considerable number arise from some disturbance in the sanitary conditions of dwellings or their surroundings, and that however improbable this may seem from a superficial or even careful examination of suspected premises, a still more thorough and extended search will often result in the discovery of some agent or agents capable of producing disease.

The chemical and physical condition of water used for culinary purposes has much to do with health, and is perhaps the oftenest overlooked by the physician in searching for the cause of sickness. We must not suppose that water is only hurtful when impregnated with the salts of lead or other metals; there are different sources of contamination, which produce the most serious disturbance upon the system. Some of these are very obscure and difficult of detection. The senses of taste and smell are not to be relied upon in examinations, as it often happens that water entirely unfit for use is devoid of all physical appearances calculated to awaken suspicion. It is clear, inodorous, palatable, and there is no apparent source from whence impurity may arise.

A few instances which have come under my observation may serve to illustrate the view presented, and as suggestions to those who are in doubt as regards the cases of patients upon their hands.

During the past summer, the writer was consulted by a gentleman residing in Roxbury, respecting the water used in his family. It was taken into the dwelling through tin pipe from a well in the immediate vicinity, and appeared to be perfectly pure and healthful. Analysis disclosed no salts of lead or copper, as indeed none could be expected from the unusual precautions taken to prevent contact of the water with these metals. Abundant evidence was however afforded that, through some avenue, organic matters in unusual quantities were finding access to the water. Careful examination of the premises disclosed the fact that an outhouse on the grounds of a neighbor was so situated as to act as a receptacle for house drainings, and from thence by subterranean passages the liquids flowed into the well. Some cases of illness, of long standing in the family, disappeared upon abandoning the use of the water.

A few months since a specimen of water was brought to me for chemical examination, by a gentleman of Charlestown, who stated that his wife was afflicted with protracted illness of a somewhat unusual character. It was found to be largely impregnated with potash and the salts resulting from the decomposition of animal and vegetable *débris*, and the opinion expressed that some connection existed between the well and the waste fluids of the dwelling. This seemed improbable, as all these were securely carried in a brick cemented drain, and in a direction opposite the water supply. The use of the spade, however, revealed a break in the drain at a point favorable for an inflowing into the well, and hence the source of the contamination. Rapid convalescence followed on the part of the sick wife upon obtaining water from another source.

Analysis was recently made of water from a well in Middlesex County, which disclosed conditions quite similar to these. The owner was certain that no impurity could arise from sources suggested, but rigid and persistent investigation disclosed the fact, that the servant girl had long been in the habit of emptying the "slops" into a cavity by the kitchen door (formed by the displacement of several bricks in the pavement), where they were readily absorbed. Although the well was quite remote, the intervening space was filled with coarse sand and rubble stones, and hence the unclean liquids found an easy passage to the water. This proved to be the cause of illness in the family.

It is unnecessary to present other instances of a similar character on record. These serve to bring to view some of the sources of impurities in water used for household purposes, and the obscure cause of serious diseases. The location of wells connected with dwellings is a matter which should receive attention at the hands of physicians.

It is well known that in the gradual decomposition of animal and vegetable substances, at or near the surface of the earth, under certain conditions, nitrogenous compounds are developed. The nitre of the earths found beneath old buildings results from these changes, although it is quite difficult to understand the precise nature of the chemical transformations which produce them. In the waters of a large number of wells in towns and cities, and also in the country, the nitrates are found at some seasons in considerable quantities. The salts form at the surface in warm weather, and being quite soluble, are carried with the percolating rain-water into the well. In cities and large towns, where excrementitious matters accumulate rapidly around dwellings compacted together, it is difficult to locate wells remote from danger, and hence it might seem that suspicion should be confined to these localities. This, however, is not a safe conclusion. How often do we see, upon isolated farms in the country, the well located within, or upon the margin of the barnyard, near huge manure heaps, reeking with ammoniacal and other gases, the prolific sources of soluble salts which find access to the water and render it unfit as a beverage for man or beast. It may no doubt be a convenience to the farmer to have his water-supply so situated as to meet the wants of the occupants of his barn and his dwelling, but it is full of danger.

Whilst admitting that such may be the conditi[on] of the water of many wells, doubts may arise wi[th] some, whether substances not decidedly poisonous, ar[e] received in such quantities, can after all be produ[c]tive of much harm, or the real source of illness. T[o] the great majority of people they are certain[ly] harmless, but it must be admitted that there is [a] class, and one or more are found in almost eve[ry] family, whose peculiar sensitive organization do[es] not admit of the presence of any extraneous agen[t] in food or drink, or in what they inhale. Th[e] functions of life and health are disturbed by th[e] slightest deviation from the usual or normal con[]dition of things around them. It is manifestly [of] importance that physicians should recognize the[se] peculiarities in individuals. It is unsafe, in makin[g] a diagnosis of disease, or seeking for causes, to ove[r]look or forget them.

We are, indeed, incapable of understanding ho[w] this can be. It seems incredible that the thou[]sandth part of a grain of one of the salts of lea[d] dissolved in water and taken daily, will disturb th[e] system of any one; and yet such is the case. W[e] can see no reason why a very little nitrate of po[]tassa, or soda, or lime, taken in the same way, shoul[d] produce any effects; still stranger it is that the in[]finitesimal amount of dust dislodged from painte[d] wall-papers, received into the lungs, should mak[e] inroads upon health.

Several instances of this latter result have re[]cently come to my knowledge. In two families o[f] the highest respectability in this city, illness of a[n] unusual and protracted character existed, and a[t] the suggestion of the physician, portions of th[e] green wall paper of the dwelling were submitted t[o] me for analysis. The pigments were found to con[]sist mainly of arseniate of copper, and upon th[e] removal of the papers the illness disappeared. I[n] experimenting with apparently the most suitabl[e] apparatus, and employing delicate chemical tests, in rooms the walls of which were covered with these arsenical papers, no evidence of the presence of the poison in the atmosphere has been afforded; an[d] this corresponds with the results of all similar ex[]periments made in this country and in Europe, so far as my knowledge extends. We must conclude that agents not recognizable by chemical tests are capable of disturbing vital processes. The evidence is very clear that in instances of illness confined to one or two members of a household, the cause may be due to some accidental disturbance with which all are equally brought in contact, but which has the power of injuriously influencing only a part. It is also clear that these sources of disease are of such a character as easily to escape detection, and therefore any facts or experience which may serve as guides to their discovery, are worthy of record.

CITRATE OF IRON AND MANGANESE.

THERE seems to be no good reason why the *citrate of iron and manganese* should not displace the well-known citrate of iron. The citrate of iron and manganese is, like the iron citrate, presented in the form of *beautiful garnet-colored plates*, which are readily soluble in cold water. The taste is very pleasant, rather pleasanter than the common iron citrate, and it may be prescribed in the same manner. It possesses the very great advantage of combining with the iron a soluble salt of manganese in just the right proportion, so that all the desirable qualities which can possibly result from the iron are secured, and, in addition, the manganic property, which is often of more importance than the iron.

The fact that iron is one of the normal elements of the blood has been universally admitted since the demonstrations of Menghini, Fork, and Laibach.

Now, as Scheele's and Gahn's discoveries in 1774

ıowed that manganese is invariably associated with on in organic nature, a suspicion arose that it existed so in organisms containing iron, and it was subseıently found not only in a multitude of plants, but so in the blood, flesh, milk, etc., as a constant ccompaniment of iron.

Fourcroy and Vauquelin had already discovered anganese in bone-ashes; afterwards, in 1830, Wur·r found it in calcined blood; Millon in 1847, larchesan in 1848, and, lastly, Hanon in 1849, rmally declared, after further diligent research, ıat manganese is the constant and natural associate ' iron in the blood.

Such facts could not fail to lead to the inference .at, as morbid elements are produced by the abnce or deficiency of iron in the blood, the same fect must likewise occur with regard to mangase, and consequently that, whenever the exhibition iron alone failed to cure chlorosis, the sole use was that chalybeates could not supply the onomy with the manganese which was wanting.

Repeated experiments soon confirmed the truth these conclusions. Numerous analyses of the ood demonstrated that the diminution of the prortion of iron in the blood of chlorotic patients as in constant ratio with the diminution of mannese, and many obstinate cases of chlorosis, which d resisted all treatment with chalybeates, were mpletely cured by ferro-manganic preparations.

These facts led Dr. Hanon to the singular theory ıich consisted in distinguishing two kinds of lorosis, one arising from a deficiency of iron, the her from a deficiency of manganese. But as Dr. anon was unable to give a diagnosis of the differce between these two kinds of chlorosis, we canıt but regard as empirical his method of administring manganese by itself in cases for which iron one had produced no result.

Chemical experiments having demonstrated, as ove stated, that manganese exists in the blood multaneously with iron, and in clearly determined oportions, the absence of one being always atıded with a proportional decrease of the other, this t supplies a most reasonable motive for the simulıeous use of manganese and iron for all cases which the exhibition of the latter alone was inficient.

The subsequent experiments of Dr. Pétrequin, d after him of Dr. Gensoul, Gubion, Contagne, nnaric, Delorme, and many more, perfectly justi-l this theory, and we can assert, without fear of or, that it is not only rational, but indispensable, many cases to prescribe ferro-manganic preparans instead of the simple chalybeates.

There is no form of ferro-manganic combination beautiful and efficient as the scales, which are fectly soluble in water, and therefore adapted to scription employment.

The scales contain of citrate of iron *seventy-five cent.*, of citrate of manganese *twenty-five per cent.* is affords the best proportion of the two agents, l meets all the possible needs of the physician.

The scales of *tartrate of iron and manganese* are ıally beautiful and pleasant, but not so *readily uble* as the citrate. The proportions in both salts the same, and the cost is also the same. These w scientific combinations may be employed in ce of the common citrate and tartrate of iron h manifest advantages. The *citrate of iron, nganese, and strychnine* may replace the citrate of n and strychnine, so well known to every physin. This preparation is in scales, and they contain same proportions of iron and manganese, with *per cent.* of strychnine.

Young Cantharides. — According to Nertwich, immature cantharis insect does not possess the stering property. It is only the adult flies that ıtain cantharidin.

PROPYLAMIN IN RHEUMATISM.

BY JOHN M. GASTON, M. D.

It is about eleven years since this article was placed before the profession as a remedy in rheumatism, on the recommendation of Prof. Aryenarious of St. Petersburg, Russia, in a report published in the "Annals de Thérapeutique" in 1857, p. 74, claiming for it specific powers of a high degree in this disease. He treated with it, in two years, — between 1854 and 1856, — 250 cases of rheumatism, acute and chronic, with all sorts of complications, metastatic, pericardial, pleuritic, meningeal, hemiplegic and paraplegic, and all recovered.

Numerous articles appeared in the journals some years ago confirmatory of these claims for it, and setting forth its uses in other diseases, as neuralgia, etc., but of late years I have not seen much mention made of it in the journals. But my own experience during the past eight years, the time during which I have been using it, has accorded so harmoniously with those reports, and that of the distinguished gentleman named above, as to give me great confidence in its usefulness, and some assurance in recommending it to the profession.

I need not attempt to give you the detailed report of the cases I have treated with it, as that would involve the consumption of too much time, but will, if you please, relate circumstantially only the first case and the last one in which I have used it. And I here take occasion to say that in no single instance have the pain and the soreness of the parts failed to yield completely in twenty-four or forty-eight hours, the cure progressing from that time on without interruption, except in two cases, occurring in individuals affected with gonorrhœa at the same time; and even in these two cases it afforded decided relief, but failed further to arrest the disease, and so did everything else that I could do, and I finally lost sight of both cases. It will be remembered here that, of all forms of rheumatism, gonorrhœal rheumatism is the most inveterate and unamenable to treatment.

My first experience in the use of this agent occurred in 1863, in the case of an interesting little girl, a child five years of age, in which all the joints of both the upper and lower extremities were successively invaded by the disease, despite my most strenuous efforts to the contrary; and fearing daily the involvment of the heart in the grand ruin, I was in an agony of anxiety and apprehension. I sought counsel, but it availed nothing as to relieving the case. At last, almost in despair, and scarcely knowing the powers of the remedy for good or evil, and unable to obtain from any source the information I wanted, I brought to bear upon the case, as a sort of forlorn hope, the propylamin, and to my great surprise and gratification, in a little less than forty-eight hours the relief was complete to the aching limbs, but I regret to say a slight valvular murmur was left in the heart.

I presume every physician, when a case of this disease has gone pleasantly with him, and yielded in apparent obedience to some new agent, has fancied that he has at last found the true remedy for rheumatism, but on the next trial it has, perhaps, disappointed and deceived him. It has been so with me in former years, and I soon learned to distrust such experience. But in the case of this, the time has been so long, and the success so uniform and so good, that it must be more than a simple coincidence.

My latest case occurred a few weeks ago, in the person of John Whitaker, a blacksmith, thirty years of age, involving the feet, knees, wrists, shoulders and elbows successively, with great constitutional disturbance, fever, furred tongue, constipation, and loss of appetite. In this case the disease was first arrested in a little *over* forty-eight hours — delayed a little beyond the usual time on account of having to stop in the midst of its use, and wait for the administration and operation of a cathartic, the patient being one of those matter-of-fact individuals, who believe in the importance of the daily performance of that particular function, sick or well. His recovery progressed satisfactorily for two or three weeks, but on the very day that he had set to go to work again he suffered a relapse, and became worse than ever. After administering a cathartic, this time in advance to make sure, I put him on the use of the agent, and in forty-eight hours he was all right again.

I may observe here, that my experience with the use of it has been confined to cases of acute rheumatism altogether — and so confident have I become of its powers that I have been in the habit for years, on first diagnosing a case of rheumatism, of promising relief in twenty-four or forty-eight hours. The cases have not been so very numerous, but, perhaps, as many as would naturally come under the attention of a physician in ordinary practice in that time.

Most cases of acute rheumatism are ushered in by chill, fever, and general disturbance, as well as pain. I usually see that the patient is in a proper condition for the use of the agent, his bowels not constipated. I sometime order a cathartic, and I frequently premise its use by administering fifteen or twenty grains of quinine in the first twenty-four hours to an adult, after which from two to six or eight drops of the liquid propylamin in a tablespoonful of water every two hours for the first twenty-four hours, and at longer intervals the next twenty-four hours, and the cure is accomplished, so far as relief from soreness of the joints and pain is concerned.

The propylamin is found in the shops in two forms, the liquid and chloride, or muriate. The former is a colorless, transparent liquid, with a singular ammoniacal and fish-brine odor; is soluble in water, and has an alkaline reaction, and, in solution of two to ten drops in a tablespoonful of water, is nearly tasteless, and is, so far as I have been able to learn, devoid of poisonous or injurious properties. Its chemical equivalent is C_3H_9N.

The chloride is in the form of white crystals, very soluble in water, one grain of which is equivalent in action to about one drop of the liquid.

The agent in either form is somewhat expensive, and that has perhaps been a hindrance to its general use. It formerly sold for five dollars an ounce in this city, but it is cheaper now, costing about three dollars per ounce. I imagine it is sometimes diluted as found in the stores, and if it should seem to fail sometimes on trial, it might be well to bear that in remembrance, and increase the dose.

It is said to exist in cod-liver oil, in ergot, in chenopodium, and in sorghum, and is extracted chemically from opium and several other sources, but the most abundant source of its supply is found in herring brine.

A very convenient formula for its administration is as follows: —

℞	Propylamin . . .	50 to 80 or 100 drops.
	Distilled water . . .	8 oz.

M. — S. Dose, tablespoonful every two hours to adult.

This is a larger dose than was used by the authority above referred to, but experience has assured me that it is within the bounds of perfect safety. — *Indiana Journal of Medicine.*

Test for Sugar in Animal Fluids. — Dr. Ehrardt gives a simple method of testing urine and other animal fluids for sugar. Add to the liquid a few drops of the following mixture: —

Natr. carb. cryst.	gr. v.
Pot. hydrat.	gr. v.
Pot. bitart.	gr. vi.
Sulph. cupri cryst.	gr. iv.
Aqua pura.	gr. xxx.

It takes after heating it, if it contain traces of sugar, a greenish yellow color; or, with large quantities of sugar, a yellowish red.

THE CARE OF THE TEETH.

In the last number of the Journal of Chemistry, I was glad to see, in an article from *The Dental Register*, the faithful use of a quill or ivory toothpick recommended. For it will tend not only to prevent offensive breath, for which it was advised, but will also do very much to prevent decay and loss of the teeth. But I was sorry to see in the same connection the remark that "as a rule, tooth pastes and powders should be eschewed as harmful agents."

That there are tooth pastes and powders that are harmful I do not doubt. But I have found by my own experience and the experience of scores of patients, that the enamel of the teeth cannot always be kept perfectly clean, by the use of toilet soap with the brush and water, nor by the use of the brush and water alone. It may be best for persons who have very offensive breath to use charcoal, but I cannot recommend its general use as a dentifrice: for I have frequently found dark spots upon the teeth of those who have used it for a considerable time, owing, as I think, to lodgment of particles of that material in the little pits and rough places of the imperfectly developed enamel. I have therefore for several years recommended a tooth powder instead; prepared from pumice stone reduced to a very fine powder, prepared chalk, pulverized orris root, and Castile soap. I have never seen the slightest ill effects, but very great benefits resulting from this, where frequently and faithfully used. The use of such a powder, together with that of the toothpick (and the latter should always be used after eating) will keep the teeth clean and smooth, and the *gums* healthy.

Disease of the gums usually results from a collection of extraneous substances upon and between the teeth, which are gradually forced under the margins of the gums, about the necks of the teeth, so that, both mechanically and chemically, they irritate both the gums and teeth.

Does any one object that the use of such a powder may wear away the enamel, and thus of course very materially injure the teeth? I never have seen any such effects from its use. I find invariably, where the enamel of the teeth is worn away, it is upon the grinding surfaces of the molars and bicuspids, and the cutting edges of the incisor and canine teeth. That is to say, the enamel is worn off only by long continued use in masticating food, and in some cases, I am sorry to say, in chewing tobacco and holding a clay pipe between the upper and lower teeth. Could the people generally be made to appreciate fully the importance of keeping the teeth always scrupulously clean, there would be much less need of the services of the dentists, and a much better appreciation of the efforts of those members of that profession who are suitably educated and otherwise qualified whenever their services should be required.

S. P. Martin.

Worcester, Mass.

MEDICAL MEMORANDA.

Salt Meat and Vegetables. — Some French physicians are of opinion that salt meat does not play so great a part in the production of scurvy as is generally supposed. Dr. Mary-Durand, in the *Siècle*, observes that the experience of the garrison of Metz is nearly conclusive on this point. The defenders of Metz were deprived of salt from the 4th of September to the 17th of October, and yet suffered severely from scurvy. Dr. Mary-Durand attributes this disease to cold and damp, to the want of fresh vegetables, to compulsory drill, and, above all, to insufficient food. He also considers nostalgia a powerful adjunct to these cases.

New Test for Blood Stains. — Acetate of zinc will completely precipitate the coloring matter of blood from solutions. The flocculent precipitate must be washed by decantation, left to evaporate and dry on a watch glass, and if blood was present the microscope will reveal delicate and beautiful hæmatin crystals. The blood stains can be dissolved in a variety of agents (for example, ether, oxalic acid, alcohol, gallic acid, and potash), and the acetate of zinc produces precipitates even in extremely dilute solutions.

Adulteration of Oil of Cloves. — Carbolic acid is said to be used for this purpose, and Fluckiger gives the following test for its detection: agitate with 50 or 100 volumes of hot water, decant the latter and evaporate it, add a little ammonia and good bleaching powder, and agitate. If carbolic acid be present, a blue color will in time appear.

Odors and Health. — This is the subject of an interesting article in a Belgian medical journal of recent date, from which we condense a few facts. A knowledge of perfumes reaches to the most remote antiquity. The Jews made use of them in the time of Moses. They were highly esteemed by the Greeks in the time of the wise but rigorous Solon. Their use was carried to excess by the Romans; and finally, in our times, they appear to have arrived at their utmost perfection and delicacy. It has been reserved also for the present day to use them in the greatest profusion. But if the perfumes that are everywhere found, and can be extracted by certain processes, may be used with safety, this cannot be said in every case of the odors that are naturally exhaled by flowers, leaves, or fruits. Their action on the economy in a limited space, and especially during the night in a closed chamber, deserves to be noticed. It manifests itself by serious disorder, headache, syncope, and even by asphyxia if their action is too long prolonged. In nervous persons numbness may occur in all the members, convulsions, and loss of voice, but in general only a state of somnolence, accompanied by feebleness and retardation of the action of the heart. This state is often associated with well-marked dimness of vision. Amongst the flowers that are most deleterious may be mentioned the lily, hyacinth, narcissus, crocus, rose, carnation, honeysuckle, jessamine, violet, elder, etc. In addition to the danger caused by their smell, should be mentioned their action on the air. During the night, flowers actively produce carbonic acid, which is injurious to health. Magendie even cites a case of death caused by a large bouquet of lilies, which the sufferer, a previously healthy woman, had in her bedroom while sleeping. Amongst the more dangerous plants may be mentioned the walnut, the bay-tree, and hemp. The action of these is well-known, the latter indeed producing a kind of drunkenness.

Iron as a Deodorizer. — Dr. Voelcker regards spongy iron as a more potent deodorizing material than animal charcoal. Sewage water passed through a filter of this substance is completely purified; and this filtered water, after having been kept six months protected from the air, is perfectly sweet, and free from any fungoid growth. The spongy iron is obtained by calcining a finely divided iron ore with charcoal. Its power of rendering water beautifully transparent, and apparently free from all organic matter, is remarkable.

Fungi and Cholera. — Mr. T. R. Lewis, a surgeon in the British Army in India, has recently published a report on the microscope objects found in cholera evacuations, illustrated with engravings of microscopic slides, executed with remarkable beauty and correctness in the office of the Surveyor-General of India. In this report Dr. Lewis has added considerably to our knowledge of some obscure points of microscopical science, while his conclusions are in direct opposition to those of Hallier and Pattenkoffer with regard to the fungoid origin of cholera. His general conclusions may be summed up as follows: 1. That no cysts exist in choleraic discharges which are not found under other conditions. 2. That cysts or "sporangia" of fungi are very rarely found under any circumstances in all the discharges. 3. That no special fungus has been developed in cholera discharges, the fungus described by Hallier being certainly not confined to such. 4. That there are no animalcular developments, either as to nature or proportionate amount, peculiar to cholera, and that the same organisms may be developed in nitrogenous materials even outside the body. 5. That the supposed *débris* of intestinal epithelium is not of this origin, but appears to result from effused blood plasma.

To Keep a Mustard Plaster Moist. — If a little syrup or molasses be added in mixing a mustard poultice, it will keep soft and flexible, and not dry up and become hard and uncomfortable, as when mixed up with water alone. A thin paper or fine cloth should come between the plaster and the skin. The strength of the plaster can be varied by the addition of more or less flour.

VALUABLE FORMULÆ.

Diphtheria. — The late Dr. Magruder, of Washington, used the following treatment with success in eighty-two out of eighty-five cases: —

The throat was rubbed frequently, externally, as soon as the swelling and soreness commenced, with spirits of turpentine. Internally, this: —

℞	Potassæ chlorat.	ʒj.
	Tinct. guaiac. comp.	℥ij.
	Tinct. cinchonæ	℥ij.
	Mellis	℥ss
	Aquæ	℥ij.

M. — S. A tablespoonful every three hours. Twenty drops of the muriated tinct. iron, an hour and a half after each dose.

Treatment in Diarrhœa in Infants. — Dr. Smith (in "Wasting Diseases of Infants and Children") recommends the following prescription if the bowels are rather loose, with dark, slimy, offensive stools: —

℞	Tinct opii	♏v
	Ol. ricini	ʒj
	Syrupi zingib.	
	Mucilag. acaciæ	aa

M. — S. A teaspoonful three times daily. In the screaming fits, accompanied by constipation, this combination of castor-oil with laudanum is valuable.

Colic in Infants. — The following formulæ will be found valuable in the colic of infants: —

℞	Pulv. rhei.	
	Fennel seed, aa.	℥ii.
	Water	O. i.

Boil until $\frac{1}{3}$ is dissipated. Dose, half a teaspoonful to half a tablespoonful, two or three times a day. It is useful in those cases attended by constipation. The addition of bromide of potassium in minute doses will, in some cases, be found beneficial: —

℞	Tr. opii.	gtt. 80
	Anise oil	gtt. 18
	Alcohol	℥i. —

Then put in ℥viii. of boiling water, first adding fine sugar, q. s., to suit the taste. Dose, half a spoonful or more, according to age.

Indolent Ulcers and Suppurative Surfaces. — Maisonneuve and Grislin recommend: —

℞	Charpie dipped in	
	Carbolic acid	℥ss.
	Spirits	℥i.
	Water	℥xv.-[illegible]

A similar treatment answers for cancer and fetid discharges of all kinds. Dr. Wolfe prefers the following, in order to get rid of the offensive smell of the acid: —

℞	Soft cotton	q. s.
	Saturate with carbolic acid —.	

Press out the excess of acid; then dry. This is to be applied to the diseased parts. The cotton thus prepared should be kept closely in a tin box.

INDEX.

THE

Boston Journal of Chemistry.

DEVOTED TO THE SCIENCE OF HOME LIFE, THE ARTS,
AGRICULTURE, AND MEDICINE.

JAMES R. NICHOLS, M. D., EDITOR.
W. J. ROLFE, A. M., ASSOCIATE EDITOR.

VOLUME VI.

JULY, 1871—JUNE, 1872.

BOSTON.
PUBLISHED BY JAMES R. NICHOLS AND COMPANY.
NEW YORK: HURD AND HOUGHTON, 13 ASTOR PLACE.
Printed at the Riverside Press, Cambridge.
1872.

BOSTON JOURNAL OF CHEMISTRY.

JAMES R. NICHOLS, M. D., EDITOR. WM. J. ROLFE, A. M., ASSOCIATE EDIT[illegible]

PUBLISHED AT ONE DOLLAR PER ANNUM, IN ADVANCE.

SPECIMEN COPIES FURNISHED FREE UPON APPLICATION.

This JOURNAL OF POPULAR SCIENCE, in the brief period of less than seven years, has attained a circulation larger, it is believed, than any oth[illegible] periodical of its class, either in Europe or the United States. Its general plan or scope is unlike that of any other publication in the world, inasmuch as [illegible] undertakes to present the living facts and the latest discoveries in at least four great departments of human knowledge. It treats of

HOME SCIENCE, THE ARTS, AGRICULTURE, AND MEDICINE,

in a way which commends it at once to physicians, druggists, chemists, teachers, farmers, mechanics, — in short, to professional and practical men o. every cla[illegible] The DOMESTIC RECIPES and FORMULÆ FOR ART PROCESSES are of themselves worth many times the cost of subscription. Subscriptio[illegible] may commence at any time. To test its value, send the publishers FIFTY CENTS, and receive it FOR SIX MONTHS. Those who take it six months a[illegible] sure to become permanent subscribers.

Address J. R. NICHOLS & CO., 34 OLIVER STREET, BOSTON.

OUR CLUBBING LIST.

On receipt of the publishers' price of any one of the following periodicals, we will send *both the* JOURNAL *and that periodical* for one year: —

LITTELL'S LIVING AGE	$8.00
THE CONTEMPORARY REVIEW (*London*)	7.50
AMERICAN JOURNAL OF SCIENCE AND ARTS	6.00
NORTH AMERICAN REVIEW	6.00
AMERICAN CHEMIST	5.00
AMERICAN JOURNAL OF OBSTETRICS	5.00
EVERY SATURDAY	5.00
GYNÆCOLOGICAL JOURNAL	5.00
JOURNAL OF THE FRANKLIN INSTITUTE (*Philadelphia*)	5.00
MEDICAL AND SURGICAL REPORTER (*Philadelphia*)	5.00
MEDICAL TIMES (*Philadelphia*)	5.00
NATURE (*London*)	5.00
N. Y. JOURNAL OF PSYCHOLOGY	5.00
PHILADELPHIA PHOTOGRAPHER	5.00
THE ECLECTIC	5.00
THE LANCET (*Amer. Ed.*)	5.00
THE PHOTOGRAPHIC WORLD (*Philadelphia*)	5.00
THE POPULAR SCIENCE MONTHLY	5.00
VAN NOSTRAND'S ECLECTIC ENGINEERING MAGAZINE	5.00
AMERICAN NATURALIST	4.00
APPLETONS' JOURNAL	4.00
COLLEGE COURANT (*New Haven*)	4.00
HARPER'S MONTHLY, WEEKLY, OF BAZAR (*each*)	4.00
LIPPINCOTT'S MAGAZINE	4.00
N. Y. MEDICAL JOURNAL	4.00
OLD AND NEW	4.00
OVERLAND MONTHLY	4.00
SCRIBNER'S MONTHLY	4.00
THE ATLANTIC	4.00
THE GALAXY	4.00
THE PRACTITIONER (*London Ed.*)	4.00
THE SAINT PAUL'S MAGAZINE (*London*)	3.50
AMERICAN PRACTITIONER	3.00
MOORE'S RURAL NEW YORKER	3.00

☞ Applications for *Specimen Copies* of any of these periodicals should be made to the Publishers of the same, to whom also all requests for missing numbers must be addressed.

☞ Subscriptions to these lists are *not entitled to premiums.*

GENERAL INFORMATION.

SUBSCRIPTIONS

May commence at any time. If no special order is given, the paper will be sent from the month in which the subscription is received. Those who wish the paper to stop as soon as the time paid for has expired, will do us a favor by stating the fact when subscribing.

ADDRESSES.

Correspondents are particularly requested to give their names in full, with their Town and State; and, in case of change of residence, requiring a corresponding change in the mailing of their papers, to give, not only the new address, but the old one also.

RECEIPTS.

A receipted bill will be sent by return mail to any subscriber who will inclose with his subscription a three-cent postage stamp, for return postage. This, however, is a needless expense, as will be seen from the following explanation of the printed mailing Label sent with each copy of the paper: —

THIS LABEL

Was devised in the interest of both subscriber and publisher, and if properly heeded, will save each no little annoyance and expense.

EXAMPLE.

Smith John Ja73

This is the only account we keep with Smith, and it answers his purpose as well as ours.

The date following indicates the issue of the paper at which the next payment *becomes due.*

When, therefore, the 1st of July, 1873, is reached, or, through inadvertence, has passed, Smith has a constant reminder in his Label that, in order to continue taking the paper, he ought to renew his subscription, according to our terms, *in advance.* Here the Label serves as a *Bill*, and ought to save the publisher postage and stationery.

If Smith is prompt in paying, we receive from him a postal money-order for one dollar, when *we alter the Label*, so that it reads: —

Smith John Ja74

It now becomes a *Receipt*, and again saves the Publisher postage. And we hereby give notice that we will consider such a mailing label as a legal receipt, and ourselves as much bound by it as if it were a receipt in form subscribed with our name.

It may happen that subscriptions arrive too late to be acknow[illegible]edged on the first paper sent out afterwards; but should the *seco[illegible]* issue bring no change in the date of the Label, the subscriber shou[illegible] at once write to us, stating, if possible, the exact date of the rem[illegible] tance, and any other facts that may enable us to trace it.

BACK NUMBERS.

As Volumes I., II., III. were not electrotyped, and all the ba[illegible] numbers in our possession were destroyed in the great conflagratio[illegible] of November 9th and 10th, 1872, it is impossible for us to furni[illegible] any portion of those volumes. Volumes IV., V., VI., and VI[illegible] have been electrotyped as issued, and we shall be able to furnis[illegible] back numbers from July, 1869, as soon as a fresh supply [illegible] printed.

Price, single copies, ten cents; six copies for fifty cents.

VOLS. IV., V., AND VI., BOUND IN ONE.

PRICE $3.50.

These, as explained above, contain all the numbers that we sh[illegible] hereafter be able to supply.

Sent by express, or as otherwise ordered (it is too heavy to go b[illegible] mail) on receipt of the price, or as premium upon fifteen subscriber[illegible] at $1.00 each.

BOUND COPIES OF VOL. V. OR VI. Price $2.00, or premium upon eight subscribers at $1.00 each.

COVERT'S PATENT SELF-BINDER. This is a very convenient style of Binder, and should be owned by all who desire to keep their files of the JOURNAL whole and clean. Price 75 cents, or premium upon three subscribers at $1.00 each.

AGENTS.

We want an Agent in every City and Town throughout the country to canvass for the JOURNAL. From the experience of our Agents during the past year, we have no hesitation in saying that the JOURNAL is one of the most profitable magazines to canvassers yet offered.

PREMIUMS.

In addition to the fine list of premiums given elsewhere, we offer anything, from a base ball to a steam engine, that is for sale in Boston. Agents have only to designate the thing they want, and if it can be procured, we will send it on the most favorable terms.

To parties who prefer cash commissions, we make the following offer: —

Upon the first four subscribers, One Dollar.

Upon all from the Fifth to the Tenth, inclusive, Twenty-five per cent.

Upon all from the Eleventh to the Twenty-fifth, Thirty per cent.

Upon all from the Twenty-sixth to the Fiftieth, Thirty-five per cent.

Upon all after the Fiftieth, Forty per cent.

DIRECTIONS FOR OBTAINING PREMIUMS.

1st. Procure Subscribers from as many different towns as you can. 2d. Send them as fast as obtained, mentioning with each name the month the subscription is to begin. 3d. State plainly in each letter that you are working for a Premium. 4th. Send the exact money with each list. Agents who work for cash will please deduct their commission as they go along, stating in each letter the number previously sent. Remit money either in Postal Orders or Drafts on Boston or New York Banks, payable to the order of J. R. NICHOLS & CO. If neither of these can be obtained, send the money in a Registered Letter. 5th. Renewals count the same as New Subscribers. Two subscriptions, at 50 cents each, for six months, count the same as one at One Dollar.

Be very careful to *write the address* PLAINLY, including Town, County, and State, and in case of renewals, please mention the fact, giving former address.

All letters requiring a written answer should contain a three-cent stamp for return postage, to ensure an early reply.

Boston Journal of Chemistry.

olume VI. BOSTON, JULY, 1871. Number 1.

Familiar Science.

ICE-MAKING IN SUMMER.

Methods of keeping warm in winter have een long familiar, but it has been reserved to e present generation to find methods of keep-g cool in summer. Our attention has been lled more particularly to this fact by various ragraphs floating around in our exchanges in gard to the New Orleans ice-making machines. seems a little singular that ice can be pro-ıced in a tropical country in midsummer eaper than it can be stored at the North in inter and shipped to the South at the proper ne.

Methods of producing intense cold have been ng known in the laboratory, but these gener-ly are very expensive, and are applicable only a small scale. A familiar instance of artifi-al cold is the common pulse-glass. This is a ass tube bent twice at right angles, with a bulb own on each end. This is partially filled with her, which is boiled to expel the air, and the be is sealed while the ether is still boiling. holding one of the bulbs in the hand a sen-tion of cold is felt, while the ether in the bulb thrown into violent ebullition.

This at first sight seems rather paradoxical, t a little investigation will show us that this not the case. All solids in passing from the id to the liquid state, and all liquids in passing om the liquid to the gaseous state, absorb heat; is heat becomes latent or hidden. It has in ct become converted into work or force, being ployed in keeping asunder the molecules of e substance.

After we have boiled the ether to drive out e air, sealed the tube, and allowed it to cool, have only an atmosphere of ether in the tube. e tension or elastic force of this will of course ry with the surrounding temperature, but by a ll-known law of physics it will never exceed maximum tension corresponding to the cold-portion of the tube. Now when we hold one the bulbs in the hand we increase the tension that portion of the tube; but instantly a cor-ponding portion of vapor is condensed in the er portion of the tube, and the tension is re-ed again. But the warmth of the hand still tinues to evaporate the ether in the bulb ich is held in the hand, giving up its own t to the ether, and this will continue until all ether is evaporated or the tension of the or in both ends of the tube becomes equal. I instead of using ether we fill the tube tially with water, drive out the air as be-, and then plunge one of the bulbs into a ture of snow and salt, the water in the other will be frozen by its own evaporation. In these cases the heat is removed by the poration, and we can always produce cold if can secure a sufficiently rapid condensation of vapor in a different portion of the same appa-ratus in which it is produced. In the earlier forms of ice apparatus, the cold was produced by the evaporation of the water itself; the vapor being condensed by sulphuric acid, which has a strong affinity for aqueous vapor. This method is still used in Paris in the production of *carafes frappées*, or frozen decanters, which are frequently used at the restaurants. The ap-paratus used resembles a small steam-boiler; this is partially filled with concentrated sulphuric acid, and then connected with an air-pump and with the flask to be frozen. The air-pump not only removes the air from the vessel, but con-nected with it is an agitator which serves to keep the acid continually stirred up, and thus prevents the formation of a layer of dilute acid on the surface of the liquid in the vessel. If the vessel contains one hundred pounds of acid originally, it will serve to freeze about five hundred pounds of water. The inventor, Mr. Edmond Carré, claims that this apparatus will furnish ice at a cost of about half a cent a pound, since the acid is as valuable for many purposes as it was before being used. The apparatus of Mr. E. Carré is, however, completely eclipsed by that of his brother, Mr. F. Carré. This in its more simple form consists merely of two upright cylinders which communicate with each other at their up-per parts. These cylinders are made of iron, and must be capable of withstanding a pressure of at least one hundred and seventy-five pounds to the square inch. The larger of these two cylinders serves alternately as a boiler and con-denser; the other, or the refrigerator, is con-structed with double walls, the inside cylinder being open at the top to receive the liquid to be frozen. In order to freeze the substance, the condenser is partially filled with a concentrated solution of ammonia in water. This solution when boiled gives off all its ammonia. Ammo-nia is a gas at ordinary temperatures, but may be condensed to a liquid by cold and pressure. The apparatus has a valve so arranged that air may readily pass out from the interior, but in so doing it must pass through water. When the condenser is heated the ammonia is volatilized, and tends to escape from the vessel; and this it is allowed to do until it has carried all the air with it. The valve is then forced down to its seat by means of a screw, and the apparatus is ready to be used. Heat being still applied to the condenser, and the refrigerator being placed in cold water, the ammonia gas soon acquires such a tension that it cannot exist in the gas-eous state in the refrigerator, and it is conse-quently condensed, a large amount of heat being given out in the operation. This heat is ab-sorbed by the water surrounding the refriger-ator. When all the ammonia has been driven over, the condenser is removed from the fire and placed in its turn in cold water, the refrigerator being surrounded by woolen cloths or any other poor conductors. The operation is now re-versed; the water becoming cooled recovers its power of absorbing ammonia gas, and conse-quently the tension of the gas is at once reduced; the condensed ammonia in the refrigerator is thrown into violent ebullition and is rapidly evap-orated. But the evaporation requires a large amount of heat, and this is abstracted from the body placed within the refrigerator, which is soon reduced to a temperature many degrees be-low the freezing point.

The capacity of the machine in this form is very limited, as it takes about two hours to pro-duce two and a half pounds of ice. The cost of this apparatus in Paris is 282 francs, or 56 dollars in gold, for one producing two and a half pounds of ice at an operation; for one producing double this quantity the price is 406 francs, or 81 dollars. Neither of these forms of apparatus is however available for the manufacture of ice on a commercial scale; but the same is not true of the continuously acting machine of Mr. Fer-dinand Carré.

This process depends like the last upon the evaporation of liquid ammonia, but the apparatus is on a much larger scale, and is quite compli-cated, although the essential parts as before are the boiler and the refrigerator; but a separate condenser is added. The ammonia passing from the boiler into the condenser is there con-densed and cooled; it is then conveyed in a liquid form to the refrigerator. Having now become gaseous again, it passes into another con-denser, which is supplied with the exhausted water which is being continually drawn off from the bottom of the boiler. This having been cooled is ready to absorb the gas again, and as soon as it is saturated it is pumped back into the boiler by a pump worked by a steam-engine. The process of freezing thus becomes continuous so long as the fire is maintained under the boiler and the pump is in operation. Ice can be produced by one of these machines at a cost of about one cent for four pounds, or five dollars per ton. Several of them are now in successful operation at New Orleans. Some curious ex-periments may be shown with these machines. Flowers and fruit may be enclosed in solid blocks of ice. Fish may be preserved in this way for transportation to distances from the sea-coast, and in fact the applications are almost numberless.

THE CRYSTAL PALACE AQUARIUM.

The latest addition to the attractions of the great "house of glass" at Sydenham is an aqua-rium on a larger scale than has ever been at-tempted before. It was built by a company with a capital of £12,000 (or \$60,000), and, though not yet fully "stocked," it has been opened to the public.

This marine menagerie occupies a building 312 feet long, 50 wide, and 20 high. One

side is taken up with sixty enormous tanks, the largest holding 4,000 gallons of sea-water. Thirty-eight of these are for the public exhibition of their inhabitants; the others contain creatures for experiments, and for replenishing the other tanks. A corresponding series of fresh water tanks is to be added at a future day.

Under the building is a vast reservoir, which is to be filled with sea-water, no less than one hundred and fifty thousand gallons of which will be required for the purpose. This enormous quantity of water is to be brought from Brighton by rail. The reservoir is so large that it takes four thousand gallons to cover the bottom to the depth of an inch. A steam-engine is at work day and night, to pump the water from the reservoir into the tanks, which are so arranged that the water falls from one into another, and thus becomes oxygenated in its progress. From five to ten thousand gallons an hour will pass through the tanks back to the reservoir, and then round again on its journey. The steam-engine is thus like a great heart, ever beating and forcing the briny fluid through all the veins and arteries of this vast circulation. All the pipes through which the current passes are made of hard rubber, or vulcanite. Even the pumps, strainers, stopcocks, and valves are constructed of this material. Iron would not do, for it would soon rust, and both the apparatus and the water would be spoiled. All the essential parts of the machinery — as the boilers, engines, and pumps — are duplicated, so that if one gets out of order, the other will be ready to supply its place without delay.

Arrangements have been made for the collection of marine animals from all parts of the kingdom, and depots for them have been established at Plymouth, Tenby, Menai, and several other places, where the "water-babies," as Kingsley would call them, are to be acclimated in tanks before being transferred to the Crystal Palace.

It is suggested that this magnificent aquarium may be made something more than a mere exhibition to gratify the curiosity of the public. Scarcely anything is known of the habits of sea-fish; but here their behavior may be watched and studied, and many disputed points in their history may thus be settled. Certain problems of no small practical importance may be solved in this way. Oyster-beds are subject to extensive depredations from creatures whose "ways" are so "dark" that nobody knows how to thwart them. They can neither be trapped nor driven away, and the oyster and his owners suffer accordingly. If the habits of these marine pests were better known, some method could doubtless be devised to circumvent them. Thus the Crystal Palace Aquarium, by adding to our knowledge of marine zoölogy, may enable us to control or exterminate animals that are mischievous, and to make those that are useful more abundant and more valuable to man.

SIR JOHN FREDERICK WILLIAM HERSCHEL.

One after another of the leaders of scientific thought passes away. The past few years have been remarkable for the number of scientific men who have ended their earthly career, and now the death of Sir John Frederick William Herschel is announced. He has occupied a peculiar position in regard to scientific knowledge. The son of the most eminent English astronomer of his day, he enjoyed great advantages in his youth which he did not fail to improve. He was graduated at St. John's College, Cambridge, where he distinguished himself as a mathematician. After completing his studies at that place he naturally turned his attention to the science which had already rendered the name of Herschel so renowned. His chief astronomical work was the completion of the map of the entire heavens, already carried to a great extent by the labors of his father, uncle, and aunt.

But it is not from his astronomical work, great as that was, that he is generally known. His literary labors in popularizing science will ever render his name a household word. No man has done so much to bring scientific knowledge within reach of the ordinary reader.

He had the happy faculty of giving accurate information, which was equally free from dry, technical details, and from the charlatanry which so often disgraces books written for popular information.

A mere list of his works, and of the papers which he contributed to various journals would fill many pages.

OZONE AND HYGIENE.

Several brief papers upon the nature of ozone have been published in the Journal, and therefore we presume it is quite well understood by our readers. Its relations to the economy of Nature form an interesting subject, and, at this season of the year, one well worthy of study. The manufacture of test paper, and the conduct of experiments upon air, are so easy of accomplishment that any one who will make the attempt will succeed. Much may be learned by careful observation, when experiments are made under varying circumstances. Dr. Cohen, of Quincy, Ill., communicates the following results of some experiments to a local paper, which are interesting: —

It is quite common, during very hot, dry weather, to hear the expression — "Oh! for a good thunder-storm to clear the air!" Those who make use of these words probably do not consider the true philosophy and science to which they give utterance; but that a thunder-storm does purify the miasmatic-laden atmosphere is positive fact, and it is the ozone generated at the time that does the work. It will not be forgotten that I have dwelt most particularly on the powerfully oxidizing nature of this substance; it acts, indeed, by carrying oxidation at once to the very highest degree. Slow oxidation of organic substances is putrefaction; rapid oxidation is combustion; and if organic germs bearing malaria or miasmata in the atmosphere, in clothing, bedding, or any other vehicle, are subjected either to a high temperature (about 300° F.), or to the influence of ozone, the result is the same: they are *burned* — consumed, and converted into innocuous, aye, even health-restoring substances; and thus from death springs forth life.

In 1858, Dr. Lankester, of London, constructed the ozonometer, on the principle of the test I have already mentioned; the standard preparation consists of one part of iodide of potassium, ten parts of starch, and one hundred parts of distilled water; this is boiled for a few moments, unsized paper is saturated with it, dried rapidly, cut into slips, and kept in an air-tight bottle or box in a dark place; when wanted for use, one or more of the slips are exposed to the atmosphere to be tested, generally for twenty-four hours, although of course, as many observations can be made as the investigator desires.

The ozonometer, as thus simply constructed, was used in London during the outbreaks of typhus fever, in 1859 and 1860; but we have more extended accounts of the observations taken during the fearful epidemic of cholera that raged in Alexandria, in June and July, 1865. For more than a month, not a trace of ozone could be found in the atmosphere above and to leeward of the ill-fated city; observations made a few miles to the windward showed its presence in considerable quantity. A southerly wind prevailed, and the neighboring villages, as also Ghizeh, Cairo, and other parts of Egypt, were exempt from the terrible scourge. From Alexandria it crossed the Mediterranean and appeared first at Constantinople, where similar observations were taken, as also afterwards at Marseilles, Paris, Madrid, Naples, and still later in London. In the infected districts, in all these cases, the ozonometer showed no change, remaining perfectly white, while a few miles to windward the reaction upon the paper was intense. During the epidemic of yellow fever in New Orleans, in 1867, not a trace of ozone could be discovered; and by the observations of Prof. Ford and myself, this condition of the atmosphere continued during the entire winter following, which was marked by the prevalence of an unusual number of cases of malarial fevers, characterized by various types. In the autumn and winter of 1868, however, according to the observations of Prof. Ford, a very large amount of ozone was constantly present, and while for the first time in many years, not a single genuine case of yellow fever was reported, and much less than the usual amount of intermittent, remittent, and typhoid fevers prevailed — influenza, diphtheria, and pneumonia became almost epidemic. We find, then, that while cholera, yellow fever, typhus, typhoid, intermittent, remittent, and other malarial fevers are attended by a deficiency, and in many cases, a total absence of ozone, an increased amount of this agent accompanies certain diseases affecting the respiratory organs.

In the daily ozonometric observations that I have taken and registered in this city, since July 1st, 1869, my experience has proved the same rule. From that date up to February 6th, 1871, there has never been, in Quincy, a total absence of ozone in the atmosphere for more than three or four days at a time; and this has occurred only in very cold weather. My professional brethren will confirm the statement that during the past two years, there has been much less of malarial disease, than ever formerly known, indeed, it may be said, a marked decrease, while on the other hand, catarrhal and bronchial affections have increased in prevalency. Within the last few weeks, there has been a remarkable exemplification of the effects of the sudden appearance of a large amount of ozone in the atmosphere; from the latter part of January to February 6th, there had been a considerable quantity indicated; and it will be recollected that catarrhal and eruptive fevers were then quite prevalent. On February 6th, the ozonometer recorded "*highly intense*," and from February 7th to March 10th, inclusive, the record was "*none*," with the exception of one day, February 26th, on which it was "*moderately intense*," and five other days, at intervals, on which there was a slight indication. During this period, the complaints I have mentioned disappeared, but, on March 11th the record was again "*highly intense*," and has remained fluctuating with a tendency to a high degree up to this day. Mark the results: influenza, bronchitis, tonsillitis (which some sharp practitioners have dignified with the title of diphtheria, a disease which never appears unless there is a *continued excessive* amount of ozone present), some cases of pneumonia, and other severe catarrhal affections

have appeared as if by magic, while intermittent, remittent, and typhoid fevers — often prevalent at this season, but never when those affections I have mentioned are rife, — are scarcely, if at all, heard of.

A GAS TREE.

Dr. J. H. Salisbury, of Cleveland, Ohio, sends us the following interesting account of a tree holding inflammable gas under pressure. It is a singular occurrence: —

"In January last, Messrs. Wallace and Nathan Salisbury, of Cortland Co., N. Y., went on to Mt. Topin to procure white oak lumber. Having selected a tree that would answer their purpose, they commenced chopping it down. The tree was two feet in diameter. When they had cut in about four inches on the east side, their attention was called to a peculiar sound issuing from the tree. Their first impression was that it contained a swarm of bees. On striking a couple more blows, the small chips and dirt commenced flying from the stump. On putting the hand down they discovered a strong current of gas issuing from a fresh crack in the stump. The odor was like that of confined air. This blowing continued for full five minutes, when for curiosity they applied a lighted match; to their astonishment the gas ignited instantly, and burned at least five minutes, with great heat, and a blue flame like that of alcohol. After the gas had all escaped they finished chopping down the tree.

"They found a hollow in the stump about six inches in diameter. Their conclusion was, that the gas was light carburetted hydrogen, and had formed from the gradual decay of the wood.

"You can rely upon this statement, as being correct in every particular."

NATURE'S ECONOMY.

Prof. Huxley, in a recent lecture, gives the following curious and striking view of a geological process: —

"Let us suppose that one of the stupid, salamander-like labyrinthodonts, which pottered, with much belly and little leg, like Falstaff in his old age, among the coal forests, could have had thinking-power enough in his small brain to reflect on the showers of spores which kept on falling through years and centuries, of which perhaps not one in ten million fulfilled its apparent purpose and reproduced the organism which gave it birth: surely he might have been excused for moralizing upon the thoughtless and wanton extravagance which Nature displayed in her operations. But we have the advantage over our shovel-headed predecessor, — or possibly ancestor, — and can perceive that a certain vein of thrift runs through this apparent prodigality. Nature is never in a hurry, and seems to have had always before her eyes the adage, 'Keep a thing long enough, and you will find a use for it.' She has kept her beds of coal many millions of years without being able to find much use for them; she has sent them down beneath the sea, and the sea-beasts could make nothing of them; she has raised them up into dry land, and laid the black veins bare, and still, for ages and ages, there was no living thing on the face of the earth that could see any sort of value in them; and it was only the other day, so to speak, that she turned a new creature out of her workshop, who, by degrees, acquired sufficient wits to make a fire, and then to discover that the black rock would burn."

After alluding to the value of coal to the arts as a fuel, he goes on: —

"All this abundant wealth of money and of vivid life is Nature's interest upon her investment in club-mosses and the like, so long ago. But what becomes of the coal which is burnt in yielding this interest? Heat comes out of it; light comes out of it; and if we could gather together all that goes up the chimney and all that remains in the grate of a thoroughly burnt coal-fire, we should find ourselves in possession of a quantity of carbonic acid, water, ammonia, and mineral matters, exactly equal in weight to the coal. But these are the very matters with which Nature supplied the club-mosses which made the coal. She is paid back principal and interest at the same time; and she straightway invests the carbonic acid, the water, and the ammonia in new forms of life, feeding with them the plants that now live. Thrifty Nature! Surely no prodigal, but most notable of housekeepers!"

BATHING IN THE DEAD SEA.

Bathing in the Dead Sea produces as novel a sensation as if you found yourself suddenly endowed with wings, and emulating the feats of a tumbler-pigeon in mid-air. You become a clumsy float, a top-heavy buoy, or swollen cork, the instant you are in its waters; and arms, legs, and body are apparently endowed with the strangest qualities. It is as if heavy weights were affixed to each, directly you attempt to move, and experienced swimmers fail in their best strokes, by reason of the unnatural buoyancy with which they have to contend. Your limbs are on the surface, and you cleave the air with your hands, the moment you try to swim; and the man who would be drowned as soon as he was out of his depth in any other sheet of water in the world, is the one best fitted for bathing in the Dead Sea. He cannot sink in it, let him do what he will. It is as if he were encased in life-belts, or sprawling on a feather-bed. If he lean back and throw his feet up, it is exactly as if he were resting in a peculiarly well-stuffed easy-chair, with a leg-rest to match. He may fold his arms, turn on one side, lie flat upon his stomach or back, clasp his knees with both of his hands, or draw his toes and head together, in the same shape the human body would assume if crammed hastily into a jar with its extremities left out, and all with no more possibility of sinking than if he was in so much soft sand. Woe to him if he be tempted by these unusual facilities to stay long in the water with his head uncovered! The bare and rocky walls of the low-lying caldron which holds the Sea of Death reflect back the burning sun and concentrate its rays; and a *coup de soleil* will be the all but inevitable consequence of his imprudence. Two of our party entered the water, and remained in it some seconds before they re-covered their heads, and the result was severe shooting pains, sickness, and dizziness, which lasted until their immersion, an hour later, in the refreshing waters of the Jordan. Woe, too, to the inexperienced stranger, who, following his rule in other bathing, dips his head as well as his body into the Dead Sea. Inflamed eyes and nostrils, together with hair and beard laden with acrid salts, are among the penalties of his rashness; while if he tastes of its waters, he becomes acquainted with a greater concentration of nastiness than had entered his imagination before. In buoyancy and bitterness the Sea of Sodom exceeded all we had heard or read respecting it; but in some other particulars our anticipations were falsified surprisingly. We looked for gloom, and we found brightness; we had imagined turbid waters, and we found a lake exquisitely clear and delicately blue; we expected perfect silence and an unbroken waste, and we found the birds singing sweetly among the tamarisks and oleanders, which spring up wherever a stream finds its way from the mountains to mingle with the mysterious inland sea.

THE PHILOSOPHER AND HIS DAUGHTER.

[The following charming poem, which has the merit of combining "instruction and amusement," and of showing the estimation which usually attends learning, was written by Shirley Brooks, and first appeared in the *Illustrated London News*.]

A sound came booming through the air!
"What is that sound?" quoth I.
My blue-eyed pet, with golden hair,
Made answer, presently,
"Papa, you know it very well;
That sound — it was Saint Pancras bell."

"My own Louise, put down the cat
And come and stand by me;
I'm sad to hear you talk like that, —
Where's your philosophy?
That sound — attend to what I tell —
That sound was not Saint Pancras bell.

"Sound is the name the sage selects
For the concluding term
Of a long series of effects,
Of which that blow's the germ.
The following brief analysis
Shows the interpolations, Miss.

"The blow which, when the clapper slips,
Falls on your friend, the bell,
Changes its circle to ellipse
(A word you'd better spell),
And then comes elasticity,
Restoring what it used to be.

"Nay, making it a little more,
The circle shifts about,
As much as it shrunk in before,
The bell, you see, swells out;
And so a new ellipse is made,
(You're not attending, I'm afraid.)

"This change of form disturbs the air,
Which in its turn behaves
In like elastic fashion there,
Creating waves on waves;
Which press each other onward, dear,
Until the outmost finds your ear.

"Within that ear the surgeons find
A tympanum, or drum,
Which has a little bone behind —
Malleus, it's called by some;
Those not proud of Latin grammar,
Humbly translate it as the hammer.

"The wave's vibrations this transmits
To this, the incus bone,
(Incus means anvil, which it hits,)
And this transfers the tone
To the small *os orbiculare*,
The tiniest bone that people carry.

"The *stapes* next — the name recalls
A stirrup's form, my daughter —
Joins three half circular canals,
Each filled with limpid water;
Their curious lining you'll observe,
Made of the auditory nerve.

"This vibrates next — and then we find
The mystic work is crowned;
For then my daughter's gentle mind
First recognizes sound.
See what a host of causes swell
To make up what you call the 'bell.'"

Awhile she paused, my bright Louise,
And pondered on the case;
Then, settling that he meant to tease,
She slapped her father's face.
"You bad old man, to sit and tell
Such gibberygosh about a bell!"

NATURAL HISTORY NOTES.

Quill-pens and Spiders. — The saying that no created thing is without its use was somewhat curiously illustrated — at any rate so far as spiders are concerned — at a sale which took place some short time ago in London. The business and premises to be disposed of were those of a quill-pen manufacturer, and the presence of vast quantities of well-fed spiders in the establishment was accounted for by one of the old employés in a somewhat curious manner. It would appear that the feathers of the goose-quill are infested by a most destructive species of moth for which spiders have an especial predilection, and therefore quill-pen manufacturers keep these insects upon the same principle that a good housewife keeps a cat. Since the days when the perseverance of a spider read Robert Bruce the lesson he afterwards utilized so well at Bannockburn, no pleasanter story has been told of this ill-favored insect.

Fish in Deep Water. — A curious experiment was performed in France, recently, to ascertain whether fish could live in great depths of water. The fish were placed in vessels of water made to sustain 400 atmospheres, under which they lived and preserved their health. It is therefore concluded that fishes may penetrate to very great depths in the ocean with impunity, as a pressure of 400 atmospheres corresponds to a depth of 13,600 feet, or about two miles and a half.

The Home of the Ostrich. — The ostrich has usually been considered as peculiar to the continent of Africa, where two species have been recognized, one belonging to the northern portions, the other to the regions nearer the Cape of Good Hope. These species were long considered identical, and their distinctness was first suggested by the difference in the texture of the egg. In a recent work by Hartlaub and Finsch on the Birds of Eastern Africa, it is shown that either the ostrich of Northern Africa or a third species was known at a very remote period in Central Asia, and perhaps even in India; and that at the present time it occurs wild in Syria, Arabia, and Mesopotamia, where, in fact, it was mentioned by the earliest writers, including Herodotus, Aristotle, and Diodorus.

HOUSEHOLD RECIPES.

A Useful Cement. — There is a first-rate home-made cement for filling up cracks in an old stove or range. The ingredients are wood-ashes and salt, equal proportion in bulk of each, little less of salt; reduce to a soft paste with cold water, and fill cracks when the range or stove is cool. The cement will soon become perfectly hard. Fire-clay (obtained at the stove dealers) will sometimes answer, but this home-made cement is always at command, where wood is the fuel used.

Perspiration. — The unpleasant odor produced by perspiration is frequently the source of vexation to persons who are subject to it. Nothing is simpler than to remove this odor much more effectually than by the application of such costly unguents and perfumes as are in use. It is only necessary to procure some of the compound spirits of ammonia, and place about two table-spoonfuls in a basin of water. Washing the face, hands, and arms with this leaves the skin as clean, sweet, and fresh as one could wish. The wash is perfectly harmless, and very cheap. It is recommended on the authority of an experienced physician.

A Parlor Vine. — To grow a very pretty vine from the sweet potato, put a tuber in pure sand or sandy loam, in a hanging basket, and water occasionally. It will throw out tendrils and beautiful leaves, and will climb freely over the arms of the basket and upward toward the top of the window. Not one visitor in a hundred but will suppose it to be some rare foreign plant.

The Arts.

THE CARBURETTING OF COAL GAS.

In an article on this subject, last September, we referred to the fact that most of the processes for improving the illuminating power of coal gas by the admixture of a hydrocarbon vapor had proved of little practical value. We stated some of the difficulties of the problem, and gave the results of the attempt, under Dr. Letheby's supervision, to economize gas without loss of light in the street lamps of London. Even when there was a gain by carburetting the gas, it did not appear to be more than 20 per cent. (according to the experiments made in England), and this, as we remarked, is too small to balance the extra cost and the risks incurred.

It appears, however, that experiments made on a large scale in this country have given more favorable results; and we are very happy to publish the following communication on the subject from one of our ablest and most trustworthy chemists: —

Fifteen years' experience has given us practical knowledge of this subject, perhaps to a greater extent than any other party in New England, for our experiments cover the carburetting of coal gas for from one thousand (1,000) to four thousand (4,000) burners, for several years.

We think it perfectly safe to state, as the result of this experience, that from 25 to 33 per cent. of the cost of coal gas can be saved without the least doubt, even when the carburetting is indifferently attended to.

There are many conditions to be observed in carburetting successfully, not the least of which is the temperature at which the gas *enters* and *leaves* the carburetters; for the rapid evaporation of the naphtha produces cold, *for which compensation must be made if we would secure uniformity of light.*

In the annexed table, we think all the essential points are covered: —

Capacity of Burner per Hour.	Pressure of Gas in Inches of Water.	Naptha burned in Gallons to 1,000 Feet.	Temperature of the Room.	Temperature of the Gas.	Strength of Light in Candles.	Per cent. of Light.	Relative Cost of 1,000 Feet.	Percentage of Saving.
3 feet.	Four eighths		75	64	4.75	100	$3.90	
6 feet.	Four eighths		75	64	10.75	237	2.65	
3 feet.	Five eighths	1.55	76	75	8.75	185	1.76	41
3 feet.	Five eighths	1.45	76	65	8.00	167	1.93	35
3 feet.	Five eighths	1.37	76	58	7.50	158	2.06	32
3 feet.	Five eighths	1.24	65	65	7.00	147	2.17	28
3 feet.	Five eighths	1.10	75	54	6.50	137	2.35	22

In the first experiment recorded in the table, gas was burned *without carburetting*, and this is taken as a standard. In the second experiment, the gas was not carburetted, but a different burner was used.

Carburetting gas in street lamps can never be successful, owing to the want of uniformity of temperature; but it does not follow, that carburetting is not successful where a uniform temperature can be secured. We are aware of the variation in the intensity of the light of carburetted gas, and have well-kept records of the same, but this does not practically enter into the question, for the simple reason, that for most practical uses, six hours' continuous illumination meets the wants of the public, and not forty hours, as in the experiment described in your article.

It is an interesting feature in the use of artificial light, that increase of light is always agreeable to all parties, and there is very slight danger of any one's complaining of too much artificial light. The more light is given, the more we are inclined to use, and still the cry is for *more light.* It is this universal craving for the best artificial light, that has prevented the more general introduction of carburetting coal gas; for the simple reason, that giving by means of carburetting a 8.75 candle light, in lieu of a 4.75 candle light of common coal gas, does not save the gas bill, but it does give 41 per cent. *more light for the same money.* Make the light equal in the two cases, and the economy will be obvious.

In your article you give the result of experiments in England with air passed through naphtha, and state that 50 per cent. of the naphtha remained, the most volatile portions having passed off. The experiment was upon too small a scale to be conclusive. We have used during the last four years hundreds of barrels of naphtha in carburetting, and we have no evidence that any non-illuminating naphtha remains in the carburetters, or has condensed in the gas pipes.

NEW METHOD OF OBTAINING CHLORINE.

Mr. H. Deacon, of the Widnes Alkali Works, England, dispenses with the use of manganese altogether in making chlorine. His method consists in passing a mixture of air and hydrochloric acid vapor over a mass of broken brick heated to 700° F., that has previously been soaked in a solution of cupric sulphate (blue vitriol) and dried. An almost complete decomposition of the acid takes place. The copper salt acts in some unknown way, as it is found at the end of the operation unchanged; the sole obvious result being, that the chlorine of the acid is set free by the oxygen of the air, with a rapidity that leaves nothing to be desired. It is well known, however, that chloride of copper gives off a portion of its chlorine by heat alone; the following may therefore be the reaction: —

$$CuCl_2 + O = CuO + Cl_2$$
$$CuO + 2HCl = CuCl_2 + H_2O$$

Although this process has not yet been worked on a manufacturing scale, considerable experience has been acquired in regard to it, and the difficulties to which it at first seemed liable have been overcome. One inevitable difficulty, arising from the dilution of the chlorine, has proved to be less serious than was anticipated; it has not been found to interfere with its application to the manufacture of potassic chlorate or of bleaching powder.

The requisite apparatus for carrying out this invention on a large scale is now being erected at the works of Messrs. Gaskell and Deacon.

THE RANSOME ARTIFICIAL STONE.

This artificial stone was originally made by treating an intimate mixture of sand, pulverized carbonate of lime, and silicate of soda, with a solution of chloride of calcium. An interchange of elements took place, resulting in the formation of silicate of lime, which became hard, and chloride of sodium, which could be dissolved out. The silicate of lime cemented the sand into a hard and permanent stone. If the chloride of sodium (common salt) is not washed out, it forms an efflorescence which injures the appearance, if not the quality of the stone.

To obviate the necessity of the inconvenient and costly process of dissolving out the salt, Ransome endeavored to dispense with the use of the chloride of calcium; and after many experiments he has succeeded in doing so. He now prepares a mixture of sand, Portland cement, ground carbonate of lime, and some silica, which is soluble in caustic soda at ordinary temperatures; from this, with soluble

lass, he obtains a mass that remains plastic long nough to be run into moulds, and gradually changes) a hard stone, which resists the action of heat and old, is impervious to water, and in process of time icreases in hardness and durability. He explains ie chemical reaction as follows: If Portland ce- ient, which consists of silicate of alumina and lime, e mixed with soluble soda, the latter is decom- osed in such a way that its silica forms silicate of me with the lime of the cement, while caustic soda liberated; this latter, however, at once re-unites rith the soluble silica placed there for the purpose f producing soluble glass, to be again decomposed y the Portland cement. The whole of the caustic oda does not appear to be liberated each time, but silicate of lime and soda is produced, and in that ay all of the soda is absorbed.

By the addition of fragments of quartz and oxide ' iron, artificial granite can be produced, and also, another way, imitation of marble, both of which e very hard, and admit of a fine polish; and they ave the advantage of the natural stone in being ist in moulds and patterns of any form.

MEMORANDA IN THE ARTS.

A Comprehensive Implement. — An English- an, who by some mistake was not born a Yankee, is invented a spade which is thus described: — he back forms, as occasion requires, a spade, a ying-pan, or a breastplate; the handle can be used a rest for the rifle, and, in addition, it can easily e transformed into a "pick" and an axe. Among ie minor details of this novel implement are a saw, hammer, and a match-box; and the whole is so ght and portable as to be easily carried on the arch.

Submarine Telegraphs. — The progress in ıbmarine telegraphy during the past year has been omewhat remarkable. The enormous length of 1,568 knots of cable was actually manufactured in 370, and no less than 11,292 knots submerged. he principal lines laid were the British Indian, e British Indian Extension (Madras to Singapore id Penang), the Falmouth, Gibraltar, and Malta, e Anglo-Mediterranean (Malta to Alexandria), e Marseilles, Algiers, and Malta, the West India id Panama, the Cuba Submarine, and sundry nall ones in connection with the British Post ffice.

Silken Newspapers. — In Pekin, a newspaper extraordinary size is published weekly on silk. is stated to have been started more than a thou- nd years ago. In 1827, a public officer caused me false intelligence to be inserted in this news- per, for which he was put to death. Several umbers of the paper are preserved in the Royal brary of Paris. They are each ten and a quarter rds long. But silken newspapers are not confined the "flowery land." The editor of the *Journal Brest* (in France), during a short stay of the ince de Joinville in that town, after a cruise, in e reign of Louis Philippe, presented the Prince th a copy of his paper printed on white satin. kewise, in April, 1839, a copy of the *Cheltenham* ng.) *Chronicle*, printed on the same material, con- ining an account of the proceedings in that town the occasion of presenting Her Majesty with a ld medal, was transmitted to the Queen.

Money Paper. — The contract for making the per for Government stamps has been awarded to e Glen Mills, Delaware Co., Penn. These mills e owned by the Messrs. Wilcox. They have obably made the raw material for more money an any other family in the world, having been gaged in the manufacture of bank-note paper for er a hundred years. The new paper is to have a re in it similar to that used in the fractional cur- ncy. This will effectually prevent any attempts at cleansing the stamps, as the color of the fibre will be destroyed at the same time that the stamp is cleaned.

The Messrs. Wilcox have been engaged in mak- ing the paper for the fractional currency for several years. It is all made under the strictest govern- ment supervision, every sheet manufactured having to be accounted for to the proper officers at Wash- ington.

PRACTICAL RECIPES.

Painting Zinc. — A difficulty is often experi- enced in causing oil-colors to adhere to sheet zinc. Boettger recommends the employment of the follow- ing composition: One part of chloride of copper, one of nitrate of copper, and one of sal-ammoniac are to be dissolved in sixty-four parts of water, to which solution is to be added one part of commercial hy- drochloric acid. The sheets of zinc are to be brushed over with this liquid, which gives them a deep black color: in the course of from twelve to twenty-four hours they become dry, and to their now dirty-gray surface a coat of any oil-color will firmly adhere. Some sheets of zinc prepared in this way, and afterwards painted, have been found to withstand entirely all the atmospheric changes of winter and summer.

To Blacken Zinc. — Zinc may be given a fine black color, according to Knaffl, by cleaning its surface with sand and sulphuric acid, and immers- ing for an instant in a solution composed of four parts of sulphate of nickel and ammonia in forty of water, acidulated with one part of sulphuric acid, washing and drying it. The black coating adheres firmly, and takes a bronze color under the bur- nisher. Brass may be stained black with a liquid containing two parts of arsenious acid, four of hydro- chloric acid, and one of sulphuric acid, in eighty parts of water.

To make Artificial Marble for Paper Weights or other Fancy Articles. — Soak plaster of Paris in a solution of alum; bake it in an oven, and then grind it to a powder. In using, mix it with water, and to produce the clouds and veins, stir in any *dry* color you wish; this will become very hard, and is susceptible of a very high polish.

Paint for Iron Work. — There is no protec- tion for iron work so efficacious as boiled linseed oil, properly laid on. The iron should be first well cleaned and freed from all rust and dirt; the oil should be of the best quality, and well boiled, without the addition of litharge or any dryer. The oil must be laid on as thin as possible, for if there be too thick a coat of oil put upon the work, it will skin over, be liable to blister, and scarcely ever get hard; but if iron be painted with three coats of oil, and only so much put on each time as can be made to cover it by hard brushing, it will preserve the iron from the atmosphere much longer than any other process of painting. If a dark coloring matter be necessary, burnt umber is preferable to any other pigment as a stain; it is a good hard dryer, and mixes well with the oil, without injuring it.

Varnish to Protect Polished Metals from Rusting. — Dr. C. Puscher recommends the use of a solution of paraffine in petroleum (1 part by weight in 3 of petroleum), as a varnish which may be usefully applied to polished metals, especially as after having brushed this liquid over the surface of the metal it may be gently wiped clean with a soft piece of flannel, so as to leave only a very thin film of the varnish, yet sufficient for the protection of the polish.

The Tredegar Iron Works, at Richmond, Va., now turn out five tons of iron to one before the war, and last year manufactured 17,000 tons of wrought and cast iron, in addition to implements, bringing $2,000,000 to the city of Richmond.

Agriculture.

CURING HAY.

Dr. P. Simonton of Maine, in some remarks regarding the curing of hay, divides the process into three methods, as follows: —

"1. The old method, which originated in the days of wooden pitch-forks — 'the more drying the better;' all the leaves and seeds dropped out and lost — all the fragrant aroma and nutrient juices gone into the air forever. This wooden pitch-fork method, from all we can see and learn, is the very poorest, as it is the one still most common in practice. Raking up and spreading out, over and over again, even in good weather, is about the idea of this over-drying method.

"2. Let the grass be sufficiently dried to remove all external moisture, and to wilt it well, — such as well stirring it in one day's sun will do; then put it in small bunches lightly forked up — not rolled — so to remain till the interior of the piles feels slightly warm; then for one day to be spread out and tended as during the first day, when, if the grass is reasonably ripe, and the weather tolerably good, it is fit for the barn. Two great advantages result from this method over the first; less labor, and saving the most valuable part of the hay, — the leaves, seed, and juices, which are largely lost in the other.

"3. When every particle of dew and all other outward dampness are off the grass, mow, and put it as soon as possible, without stopping for it to wilt, — certainly before any moisture comes upon it, — where it is to remain in the barn. When it is all in, or when for any reason the work is suspended for a few days, cover the top of the hay with a foot of straw or other cheap material. It is claimed for this method that it is a great saving of time and labor, and that every valuable property of the hay is saved; especially its juices, so nourishing and so relishable to the stock, and which serve as a natural pickle to preserve the hay. In a few days the hay heats and ferments, causing a dense steam to rise to, and lodge in, the upper foot of the heap, spoiling it; hence the use of the straw, to receive the steam and save so much hay.

"Last year many of the agricultural publications spoke of this new (No. 3) method, and advised a trial of it. But we do not so much allude to it here for that reason, — for there is no absurdity so great that it does not have powerful advocates somewhere: the famous Farmers' Club of New York city, which so often sends out, through the *Tribune*, its wordy-wise and often ridiculous advice and instruction, being composed, it is said, of 'doctors without patients, lawyers without clients, and clergymen without parishes,' — but because it was last year tried in this locality, the results of which trial, if known, may lead to future profit. And the person who has tested the thing, who is a practical and intelligent farmer, has kindly furnished the following for publication: —

"Dr. P. Simonton, — *Dear Sir:* In reply to your inquiries respecting my experience in putting hay green into the barn, I will state that early in last haying season, before the grass was fully ripe, one morning, beginning at nine o'clock, the grass being perfectly free from dew and all outward moisture, I mowed, by machine, two tons of grass, which with the help of two boys I put upon the scaffold in my barn by two o'clock the same afternoon. That was all I did to it. It went through a process of heat and sweating which caused the upper layer, perhaps 10 or 12 inches thick, to spoil for eating purposes. All below this proved excellent hay; some of the leaves turned dark, but nearly all the useful parts, which are lost by the drying method,

being saved, it was very rich in fodder, and was much better relished by the stock than common dried hay. Specimens of it can now be seen on my premises, and at the Selectmen's office in this town. I intend to cure my hay in the same way this season on as large a scale as the weather will permit. Covering it with some cheap material, like straw or refuse hay, would be a saving. Thanking you and all who take an interest in these matters, I am

"Yours respectfully, WM. M. LARRABEE.

"SEARSPORT, *June* 24, 1869."

REMARKS. — We have always advocated cutting hay early, and drying it less than is the practice of many farmers. To properly secure the hay crop is the most important work the farmer is called upon to perform, and the want of judgment and common sense in conducting the labor causes the most serious losses. It will not do to advise farmers to follow Mr. Larrabee's method, and yet we are certain it is safe, and the best under certain conditions. During the dry, hot days in July, when but little dew drenches the grass in the morning, it may be safely cut and housed the same day. With the use of a hay-tedder and in the absence of dew in dry weather, two thirds of the hay grown upon any farm may be placed in the mow without cocking in the field, and the quality be much improved. Let farmers try some apparently *hazardous* experiments in a small way during the present season, in storing partially cured hay, and they will learn some most important and instructive facts.

UNOCCUPIED LAND.

WHILE there is a narrow strip of country on our Atlantic coast, extending from Portsmouth, N. H., to Philadelphia, which approximates the countries of Europe in the cultivated condition of the soil and the density of the population, the rest of the United States is only settled in spots and oases. Human occupancy is the exception, and the wilderness condition the rule. Massachusetts, Southern Maine and New Hampshire, and Rhode Island and Connecticut have the aspect of old countries, brought under human subjection. But a greater part of the soil of even the old Thirteen States is still unoccupied and unreclaimed. The railroads of the West and South run through wildernesses for the most part. The greater portion of the old State of New York is a wilderness, and yet settlers have been going West from that State for a generation and more. Only the choice spots and localities of our vast territory are taken up. Settlers are dainty. Our oldest States are not yet settled. Large as is the stream of emigration flowing from Germany, Great Britain, and other European countries into the United States, it is only a drop of water in the bucket. Some four millions and a half of European emigrants have landed at New York during the past twenty years. It would take all this host to settle Northern, Central, and Western New York alone, and even then that State would not begin to approximate the crowded condition of such European countries as France, Belgium, Bavaria, etc. The North American continent can furnish homes and abundant food for all comers for centuries. Land, which is so precious in the Old World, will continue to be a drug here for an indefinite period of time. Nobody with a spark of enterprise need be a drudge in our old Eastern commercial and manufacturing towns and cities. There is a piece of soil with abundance and independence for everybody. This fact makes trade unions and labor leagues, modelled on those of England and other European communities, ridiculous. The Secretary of the Treasury recently said, in a speech before the Chicago Board of Trade, that if we were to aggregate the entire population of the States and Territories of this Union within the boundaries of the State of Texas, and leave the whole country elsewhere uninhabited, the population to the square mile would not exceed the present population of Massachusetts. — *Boston Courier.*

AGRICULTURAL BREVITIES.

CROPS IN EUROPE. — The *Mark Lane Express* (London), of May 23d, gives a gloomy account of the crop prospects in England and on the Continent of Europe. It says the week before was very cold, with snow in the north. Grass received a severe check, and the grain crops were very backward on that date, with a certainty that the yield will be below rather than above the average. In the southern countries of Europe and on the Barbary coast, there has been a severe drouth, and a general backwardness of crops is the feature all over the Continent. On the other hand, the stock of wheat and other grain in store is much smaller than usual at this season, and the price of wheat in England was 58s. 7d. against 44s. 5d. in 1870. From present appearances Europe will call for a large supply of breadstuffs from this country this year, and will have to pay us good prices.

FARMING IN MASSACHUSETTS AND IN NEW JERSEY. — The following statistics are gleaned from the reports of the last census: —

The area of New Jersey is about 200 square miles less than that of Massachusetts, but it has 240,000 more acres of improved land, 12,000 more of woodland, and about 7,000 more of other unimproved land. The cash value of farms in New Jersey is $257,523,376 against $180,250,338 in 1860, a gain of more than 42 per cent. The cash value of farms in Massachusetts is but $116,432,781, or less than half New Jersey's; yet the farm products of Massachusetts are valued at 32 millions, and in New Jersey less than 43 millions, — only a third greater. The orchard products of New Jersey are nearly $1,300,000, of Massachusetts $940,000; the market gardens of New Jersey, which supply New York and Philadelphia, produced nearly three million dollars in 1870, while those of Massachusetts produced a million dollars less. These products have nearly doubled in New Jersey since 1860, while in Massachusetts they have increased 41 per cent.

MIXED FARMING. — The *Farmers' Herald* (Chester, England) forcibly says: "Mixed husbandry is needful to realize the full amount of profit which the farm properly managed will yield. Every year the price of farm products varies: some will be high and some low, and thus the farmer catches good prices for a part, if not all; whereas, if he is wholly dependent upon one kind of crop, he may be wholly disappointed. A little sold of everything makes a muckle, and if one thing does not pay, another will."

THE POTATO BUG. — This interesting insect does not appear to be a favorite article of diet with many of the animal creation. It has been stated that the only creature that will eat it is a certain species of snake; but it now appears that ducks have an appetite for it. A gentleman of Piqua, Ohio, put a pair of Muscovies into his potato patch, which was literally swarming with the bugs. The ducks ate the bugs with such avidity that the latter were soon exterminated, and the patch has not since been troubled with them. The ducks did not appear to suffer any ill effects from eating the bugs.

THE PEANUT CROP. — Previous to 1860 the total product of peanuts for the United States did not exceed 150,000 bushels, and five sixths of the whole amount came from North Carolina. Now, North Carolina produces 125,000 bushels; Virginia, 300,000; Tennessee, 50,000; Georgia and South Carolina, each, 25,000; while from Africa co[me] about 100,000 bushels each year. 550,000 bush[els] are now sold annually in New York.

AMERICAN CHEESE IN LONDON. — An exchan[ge] prints a letter from a friend who has been exami[n]ing the cheese-markets of London. He believes th[at] if a superior quality of cheese be sent, there ne[ed] be no fears of the market, and that the recent fa[ll] in price was not caused by excess in quantity [of] the market, but by the inferior quality. He al[so] states that the quantity of Swiss cheese supplied [to] the London market will be much lessened, from th[e] large amount of condensed milk now sent from th[at] country, of which a great deal is sold in London.

THE MARSHALL P. WILDER STRAWBERRY. — This new berry with a very long name we hav[e] fruited the present season, and it appears to b[e] quite a desirable variety. It resembles the Agricu[l]turist in form, and in flavor it is like the Russe[ll's] Prolific, but it is a harder berry than the latter, an[d] handsomer than the former. We judge it to be [a] good bearer, and well adapted to market or famil[y] purposes. It will however require the experien[ce] of another year to enable us to speak positively re[-]garding it.

DROUGHT AND WORMS. — The crops at Lak[e]side are suffering from the effects of the almost un[]paralleled spring drought which prevails in th[is] section. No rain has fallen for five weeks up to th[e] time of writing (the second week in June), and th[e] tender grass shoots are pinched and dwarfed f[or] want of water. Corn has barely made its appear[]ance above ground, the wheat looks brown an[d] wilted, and altogether the prospect is not a pleasin[g] one. To add to the feeling of general discourage[]ment, the terrible canker-worm has made its ap[]pearance, and the fine apple-trees are turning brow[n] under the effects of its ravages. It is difficult t[o] know why this filthy pest is permitted to cut it[s] way through our orchards, in defiance of all th[e] devices of man for his destruction. No plan of suc[]cessful warfare has as yet been devised, and th[e] problem is a difficult one to solve. We intend t[o] commence a series of experiments having in view the destruction of the worm, if we can secure a few moments of leisure.

RECIPES FOR THE FARM AND HOME.

WHITEWASH. — The following recipe is one o[f] those endorsed by the Light House Board of th[e] United States: —

Slake half a bushel of unslaked lime with boil[]ing water, keeping it covered during the process. Strain it, and add a peck of salt dissolved in warm water; three pounds of ground rice, put in boiling water, and boiled to a thin paste; half a pound o[f] powdered Spanish whiting, and a pound of clea[r] glue, dissolved in warm water: mix these well together, and let the mixture stand for several days. Keep the wash thus prepared in a kettle or portable furnace, and when used put it on as hot as possible, with painters' or whitewash brushes.

POTATO STARCH. — To make starch from potatoes, wash your potatoes clean, then pare them. Take a large grater, and grate them into a tub of water. After it becomes settled drain the water off, putting fresh on again, pouring and changing about three times, when the starch will be ready to dry. This is done by spreading it out on paper or muslin, and it will be dry in a very short time.

A CHEAP ICE CHEST. — A correspondent in Indiana sends us the following directions for a home-made ice chest: Take two drygoods boxes, one of which is enough smaller than the other to leave a space of about three inches all around when it is placed inside. Fill the space between the two with sawdust packed closely, and cover with heavy lid made to fit neatly inside the larger box. Insert

small pipe in the bottom of the chest to carry off ıe water from the melting ice. For family use ıis has proved quite as serviceable, and as econom- ıal of ice, as more costly "refrigerators."

RHUBARB VINEGAR. — Excellent vinegar may ẹ made from the rhubarb plant in the following ɪanner: For *five* gallons take 12 ordinary sized alks of rhubarb; pound or crush them with a piece ' wood in the bottom of a strong tub; add 3 gal- ıns of water; let this stand 24 hours; strain off the ushed rhubarb, and add 9 pounds of sugar free om molasses, and a small teacupful of the best rewer's yeast; raise the temperature to 65° or 68°, ıd put into a 12-gallon cask; place it in a position here the temperature will not fall below 60°. In a onth strain off from the grounds, returning it to the ısk again, and let it stand till it becomes vinegar.

TO DYE WOOLEN BLACK. — Put one pound of ıtract of logwood into an iron kettle, add three ıilfuls of rain-water, and let it dissolve over the ṛe; then put three ounces of blue vitriol into it, irring until it is dissolved. Now put in your oolen yarn, or woolen goods, and boil very gently ɔout an hour, stirring well, to prevent spotting. ry in the air; then wash well in soapsuds, and ınse. This recipe will color three pounds of yarn · cloth a fine black.

TO REMOVE THE TASTE OF WOOD. — A new ıg, churn, bucket, or other wooden vessel, will ɛnerally communicate a disagreeable taste to any- ing that is put into it. To prevent this incon- ınience, scald the vessel well with boiling water, tting the water remain in it until cold; then dis- lve some pearlash or soda in lukewarm water, lding a little lime to it. Wash the inside of the ssel well with this solution. Afterward scald it ell with hot water, and rinse with cold water be- re using it.

TO SAVE FRUIT WITHOUT SUGAR. — Put in ide-mouthed bottles; fill up with cold spring water. ıt them in a vessel of water up to the neck; boil ılf an hour; tie bladders or oil-skin over tight, or rk and seal while hot. Let them set until cold. ıep in a cool place. Use as soon as opened. ıck hay around while boiling to steady them.

TO HULL CORN. — Take one quart of strong lye, ɛpared as for making soap, and two quarts of ıter. Put the corn into this for boiling, and let it il till the hulls begin to start, which you can find t by washing a few kernels in cold water. Then ıce the corn out, and rinse it in one or two waters. ıt it in cold water again, and let it remain over ẹ fire until it boils; after boiling five minutes ıse it till all the lye is removed. To cook it, boil ır hours slowly, add salt to your taste, and let it il half an hour more.

HOOD, in his *Comic Annual* for 1830, communi- ted the following from a contributor: "Sur, my f had a tomb cat that dyd. Being a torture shell d a grate faverit, we had him berried in the guar- ın, and for the sake of inrichment of the sile, I d the carkis lade under the roots of a guzberry ısh, the frute being, up till then, of the smooth nd. But the next seson's frute after the cat was ırried, the guzberris was all hairy, and more re- arkabul, the catpilers of the same bush was all of e same hairy discription."

IN the Hagenau forest, in Alsace, an oak-tree is be seen, whose age is estimated at 1,300 years. he trunk and main branches are hollow from de- y, but the tree stands firmly, and continues to put rth fresh foliage every year. Near Groenenberg, the Prussian province of Hanover, a beech-tree to be seen, which was planted in 1668 in remem- ance of the Peace of Westphalia, concluded in at year, by which the Thirty Years' War came an end.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, JULY 1, 1871.

HOW WE STAND.

IN commencing a new volume (Vol. VI.) we venture upon a few statements regarding the progress and success of the JOURNAL, and our past and present aims. At the commencement of the last volume the paper was enlarged, and the price raised to one dollar a year, and we are pleased to state that this change has resulted greatly to its benefit. It is always hazardous to make radical changes in successful journals, and they are oftener fraught with evil than good; but so strong a hold had the JOURNAL upon the regard of its patrons, that out of more than a *score of thousands of subscribers*, scarcely a *single hundred* relinquished it on account of the change, while during the year every month has added hundreds of new members to our family of readers. It is in no spirit of boasting that we are led to remark, that probably no popular journal of science in this country or in the Old World has a wider circulation, or exerts a greater influence than the BOSTON JOURNAL OF CHEMISTRY at the present time. For this we are indebted to the enthusiasm and kind efforts in its behalf of a little army of stranger friends, who have worked with untiring assiduity for its welfare. Through their efforts it has found its way into every nook and corner of our widely extended country, and into foreign lands, and we trust it is a messenger of good, and not of evil, to the many happy families who receive its monthly visits.

We have labored from the start with the expectation that a respect for science might be engendered in the popular mind, that the youth of our country might be stimulated to higher aims, that a taste for scientific investigation and observation might be excited, and that a class of reading which leads the mind into channels hurtful and immoral might be rendered distasteful and consequently avoided. We have aimed to correct pernicious errors, to expose shams and delusive schemes, to point out sources of danger to public health, and to promote the sanitary welfare of individuals and families. We have aimed to raise the noble pursuits of agriculture to a higher plane, and to place husbandry, so far as possible, among those pursuits which are guided and governed by known scientific laws and facts. We have presented so much of astronomy, medicine, and pharmacy as would serve to show what progress was being made in these departments of science, and at the same time to interest the reader, and excite that respect for them which is their due. The efforts of charlatans and quacks have done much during the past twenty or thirty years to excite vulgar prejudice against the scientific treatment of disease, and we have preferred to furnish medical facts and principles in the language and with the technicality peculiar to the science. Of all the sciences, that of medicine is the most difficult and hazardous to attempt to make plain to the common apprehension. It is hazardous because it is apt to lead to presumptions, on the part of the imperfectly informed, which might result in disastrous consequences.

Our journal has been conducted in the belief that science, in most of its departments, can be *popularized* without being *vulgarized;* that the great principles which govern and control natural laws may be made plain to ordinary minds or to the common class of readers, without in any degree compromising the dignity or accuracy of science in any of its aspects. We believed the people would generously support an undertaking having these ends in view, and in this we have not been disappointed.

Of course, a journal so positive and independent as this must have its enemies as well as friends. We should be troubled were it not so, for in our view journals or individuals without enemies are poor affairs, and afford evidence of a want of moral courage, which is despicable. It is much easier to float along in the smooth current of ready acquiescence, or to avert the eyes from that which is selfish, erroneous, mean, or vulgar, but it is less honorable. While the JOURNAL has been open and fearless in its exposures of errors and absurdities, and in its criticisms of men and things, it has not, as our readers very well know, been a roving corsair, ready to pounce upon anything and everything which might invite attack. We have never intended to do an act of *injustice* to any individual, or to any plan, scheme, or device which may have come under notice; and if errors or wrongs of this kind are unwittingly committed, a prompt disclaimer or explanation will be made.

But few changes will be made in the conduct of the JOURNAL during the year. It will remain under the same editorial supervision, and will continue to be printed at the Riverside Press and published by Messrs. H. O. Houghton & Co., as formerly. It is proper to state that we have made arrangements with some of the most distinguished scientific gentlemen of the country to furnish short popular articles upon scientific topics, which we trust will add to the interest of the JOURNAL. The editor will, if health and strength permit, furnish more of the essays which have proved so welcome and interesting to our readers upon the chemistry of familiar objects, and also resume the publication of the series of farm papers, entitled "Shore Pencillings at Lakeside."

THE DARTMOUTH OBSERVATORY.

Professor Young, the accomplished astronomer and spectroscopic observer, who has done so much for the honor of American science abroad, having returned from the eclipse expedition to Spain, is devoting himself with extraordinary ardor to his favorite investigations at Dartmouth. He found upon his return that the instruments at his command were entirely inadequate to enable him to push his researches beyond the limits already attained, and consequently he has set about seeking funds to enable him to procure telescopes of increased power. He needs at least $5,000 to put everything about his observatory in good condition, and he ought to have it at once. If he needs $100,000, the friends of science and learning must promptly respond to his needs, for he is engaged in a *great work*, and he brings to that work extraordinary powers of analysis and observation. We think it only necessary for Professor Young to make known his wants, and the friends and patrons of science will most gladly supply all needed funds. If the indefatigable astronomer is willing to devote all the powers of his mind and body to the arduous, self-denying labor of observation, the least we can do is to keep him well supplied with instruments.

Alvan Clark & Sons, of Cambridge, are making for Professor Young a fine telescope with 9½ inches aperture, and 12 feet focus. This will be a great improvement upon the small, imperfect one with which he has made so many important discoveries. When this is mounted, and everything in his observatory put in suitable condition, we shall look with much interest to the results of further continued patient research.

LIGHTNING RODS.

At this season of the year, when thunder-storms are of frequent occurrence, and considerable damage is done to buildings, and human life is placed in jeopardy, the question regarding the measure of protection afforded by rods upon buildings is discussed with much interest. It is a pity the matter should be one of doubt or uncertainty, and when rightly understood it ceases to be such. Properly constructed rods, placed upon buildings in a proper manner, afford absolute protection against any electrical discharges which are liable to occur in thunder-storms, and this should be clearly understood by every one. Public confidence has been weakened in regard to the efficacy of rods, by the frequent attacks made upon buildings to which they have been affixed; but this affords no evidence that they are worthless in principle. It rather affords proof that the rods were badly constructed, or that they were adjusted in a careless, unscientific manner. During the past twenty years we have made it a point to investigate, personally, every instance of the kind which occurred within our reach, and in every one palpable defects were discovered in the arrangement of the rods.

The defects most generally found have been in the ground connections of the rods; and we venture to assert from what we have learned by investigation, that a large part of the rods put upon buildings by ignorant, irresponsible "peddlers," afford no measure of protection at all. Quite recently it came to our notice in repairing a building, that the rods penetrated into the dry surface soil only about *two feet.* The rods were well enough, but the house was unprotected in consequence of the imperfect earth connections. Peddlers carry with them a crow-bar, and with this they make little superficial orifices in the ground, and thrust in the ends of the rods, caring nothing for the consequences which may result from their negligence. Usually they claim earth penetrations of eight or ten feet, and take pay for that extent of rod, and it is time this form of fraud was stopped. Every person who desires to protect his buildings must attend personally to having them adjusted. He must *know* that the rods penetrate to a point where permanent moisture is present, which cannot be less, in ordinary soils, than eight or ten feet. The terminals should be constructed of copper, and it is always desirable to have them placed in a well, or attached to iron water-pipes, if the service-pipes of the building are of lead or tin. As regards the form of rod, the old-fashioned, large iron rod is best, and it may be attached to buildings in any way most convenient. The pretty glass insulators, so largely used, are unobjectionable, but they are quite unnecessary; they do not add to the measure of protection, or increase the value of the conductors. There are a half dozen different forms of what are known as "cable rods" manufactured, which are constructed of a bundle of small copper and iron wires bound or twisted together. These, for the most part, are of good size, and well adapted to the purposes for which they are designed. With good rods carefully and scientifically adjusted, a perfect sense of security may be entertained by the owner or occupants of buildings.

HOUSEHOLD WARMTH.

It affords us great satisfaction to learn that the wrought-iron air-furnace which we devised a year ago, contributed so essentially to the health and comfort of those who used it during the past winter.

Among many letters received from those who used the furnace with great satisfaction, is the following, from the honorable and venerable N. P. Trist, who negotiated the famous Mexican treaty, under Mr. Pierce's administration, and whose claim for the service has just been paid by Congress. It was not designed for publication, but there is no impropriety in presenting it, as it relates to a sanitary matter of much public importance: —

Alexandria, Va., *January 30th*, 1871.

"Dr. Nichols: — *Dear Sir.* Nearly two months have elapsed since the air-furnace you devised was procured from the makers, Messrs. Lebosquet Bros., of Haverhill, Mass., for the house occupied by me here. During the whole time I have been kept in-doors by a lameness which forbids my walking or even standing. I am the better able therefore to speak of the merits of the furnace as a house-warming and ventilating contrivance.

"As respects the first object (warming), its efficiency is of course not affected one way or the other by its being made of wrought-iron, but as respects the *quality* of the air supplied by it the case is far otherwise. In the course of my life I have lived as tenant, or boarder, or visitor, in houses warmed in all ways; by wood and coal, in open fire-places and stoves, by steam, and by air passing over cast-iron furnaces, but never before have I had such air to breathe within doors as that we have all been enjoying this winter. Not a day has passed but the difference has forced itself upon my attenti all the more strongly from my having been troul with a bronchial affection which compelled me reside for many years in a tropical climate. annoyance from it this winter has been much than usual, and for this, and more important for not having my general health impaired by a l confinement, I believe myself indebted wholly to pure air I have breathed — air *unpoisoned* by d terious gases. Last winter, in the same hou warmed by *cast-iron* Baltimore heaters, connec with the same flues, we were all made unpleasan conscious of the presence of these gases in the roo many times every day.

"So very important in my estimation is this b efit — vitally important before as a matter of sci tific knowledge, but now *brought home* to me a matter of personal experience — that nothing wo induce me to accept any other mode of warmin house. Very truly yours, N. P. Trist

LABORATORY FOR ANALYTICAL WORK

The demands on our time for a long while ha been so pressing, we have been compelled to ref many of the requests made by patrons and frie for analytical work. This has been a source much disappointment to those who have wished our services in the examination of waters and co mercial substances, for the detection of deleteri agents, adulterations, etc. In view of these fa we have been led to establish, in connection w our laboratory for industrial products, one for stric analytical work, and to complete arrangements conducting chemical analysis of such substances may be sent to us. This laboratory is in charge Mr. S. P. Sharples, who has been the assistant Prof. Gibbs of the Lawrence Scientific School, Ca bridge, during the past five years, and whom we gard as one of the most accurate and accomplish chemists in this country. The substances a agents to which we can give attention embrace wide range. We will make analysis of cister spring, well, or pond waters, or of nitre, soda, i digo, bleaching salts, pigments, colors, wall pape articles of food, substances suspected to cont poison, in short all articles known to commerce, used in the arts or in medicine. Special attenti will be given to work connected with medical che istry, such as the examination of urine, and urina deposits, blood, sputa, etc.

Persons in any part of the country desiring an lytical work, can send to the editor of the Journ. through the mail or by express, and prompt atte tion will be given to their commands.

EDITORIAL NOTES.

American Telescopes. — In the manufactu of optical instruments, we are at this time leadi all the nations of the earth. American microscop spectroscopes, and telescopes are certainly superi to any made in Europe, and this is acknowledg by some of the best scientific observers of Engla and Germany. Tolles's and Wales's objectives a of the highest excellence, and none better have ev been produced. The telescopes of the Messr Clark, at Cambridge, stand at the head of all i struments of this class which are now made, an their orders, from parties at home and abroad, a much greater than they can promptly meet. The celebrated makers have recently received orders f *two telescopes, of 25-inch aperture,* which, whe completed, will be the largest instruments in th world. The largest hitherto made has an apertur of 24 inches.

The Pittston Coal Mine Disaster. — W have recently returned from a visit to Pittston, Pa the scene of the sad disaster by which a large num ber of men and boys lost their lives. The mine i

s...ated in a most charming locality, just upon the ...skirts of the thriving village of Pittston, with ...ling meadows and hills around, and orchards ... grass above it. In this neighborhood there ... now sixteen widows, and three times as many ...hans, who have been made such by the terrible ...ualty. In conversation with the men that es...ed, we found that there was experienced but ...e physical suffering on their part. They nearly ... became unconscious, but passed into that con...on by a process which resembled sleep. The ...d suffered but little except from mental anguish. ...o mules were pointed out to us grazing in a ...dow which were taken from the pit after being ...it *seven days*. It is the opinion of the brave ...ineer and the proprietor that all could have been ...d if the proper course had been pursued by the ...risoned miners.

...INNESOTA A HOME FOR INVALIDS. — Dr. B. M...tocks, who has been for the last four years S...erintendent of Health at St. Paul, Min., has w...ten an interesting and very suggestive book re...rding the advantages of Minnesota as a Home fo... Invalids. Dr. M. has had the very best facili...ti... for observation in that section, and his high st...ding as a physician is an assurance that his st...ements and conclusions are reliable. The open...in... chapters are devoted to the cause and treatment of ...onsumption, and then follow those which have st...t reference to the climate and the hygienic in...ences of the State. Physicians and invalids sh...ld consult this book.

...EPUDIATION. — This is not a chemical topic, b...is one so closely affecting the best interests of a ce...ain section of the country that we cannot refrain fr... alluding to it. It is stated that the young ar... thriving State of Minnesota has by actual vote re...diated a portion of her State debt, and now we le...n that St. Paul, the largest city in the State, is re...rained, by action of a city jury, from paying the co...ons upon a portion of her bonds. No greater in...y could befall the city than conduct like this; it ... more disastrous to her fair fame, and business in...ests, than fire or famine. It is disastrous to the in...ests of the whole West, for if there is the least lo... towards dishonesty, not a dollar of Eastern ca...al can they borrow to carry forward the works of ...ternal improvement upon which their prosperity de...nds. Minnesota and her capital city must im...diately look to their interests.

...YNDALL ON HERSCHEL. — We have elsewhere re...red to the death of Sir John Herschel, which ha...called forth many tributes to his memory in for...gn journals. In one of these the writer, while do...; justice to much in Sir John's character, re...ma...ed that his great fault was a habit of flattery, wh... even affected his honesty as a critic and re...vie...r, and his manners as a gentleman. In a let...ter ...the *Daily News*, Professor Tyndall thus vin...dic...es his friend's memory: "I think it was in 18..., and in presence of a Friday evening audience at ...e Royal Institution, that Faraday introduced me ... Sir John Herschel. From that hour to this, th...gh the advancing years, his character has gr...n in beauty to me. As I knew him better, re...spe... ripened into reverence, and until I read the wo...s of your correspondent, this feeling never en...cou...ered from the expressed opinions of others the sli...est shock. During the past week I have sou...t to check and extend my data by reference o...ler men. I have conversed with many whose in...acy with Sir John Herschel extended far be...yon... the range of mine, and if their unanimous and ...nant testimony be worth anything, I should ...te to write the term that would most fitly de...scri... your correspondent's quoted words. He ma... perhaps, be able to make good his position, an...e may even have the courage to give his name; but ...s it now stands, I must regard his article, notwithstanding its apparent warmth of appreciation, as embodying the most conspicuous personal wrong to which anonymous writing has of late years given birth."

COMPLIMENTS FROM OVER THE OCEAN. — A London paper says of the JOURNAL: "We give it a cordial recognition as likely to interest and instruct every member of a household as well as a man of science. It is edited with an ability that is at once open and frank, and in a popular manner which English journals of a similar character cannot even imitate. We wish such a periodical could be placed on the table of every thoughtful family in the land."

An English gentleman, who has received the paper for the past year, writes in a similar strain in a private letter, from which we venture to quote the following sentences: "I have longed to tell you how much your entertaining and instructive journal is relished by myself and family. . . . . I know of no periodical we have in England, that resembles it in variety of contents and in the curious *mélange* of the scientific and the practical (though of course these are often twain made one) that is served up in every number."

ZINC WATER TANKS. — In a French medical journal of recent date, there is an article by M. Zinrek on this subject. He has found that the water dissolves the more zinc in proportion as it contains more chlorides, and also in proportion to the length of contact. Boiling does not, however, precipitate the zinc from water charged with the metal. A sample of the water was tried, in which the chlorides were in small proportion, but which had been a long time in a zinc tank. As much as fifteen grains of zinc was found in each quart. To prevent this state of things, the author advises the zinc tanks to be coated inside with an oil paint, the basis of the paint being ochre or asphalt. No minium, ceruse, or carbonate of zinc should, however, be used. Better than painting it, is to discard its use for this purpose altogether.

THE SPHEROIDAL STATE OF LIQUIDS. — From Leidenfrost's experiments, it seemed probable that a drop of water assumes the spheroidal state when the tension of the steam formed at its under surface is sufficient to support the pressure of the atmosphere plus the weight of the drop itself, and that, therefore, if the pressure be removed, a lower temperature must suffice to cause the phenomenon. E. Budde has proved this experimentally by means of the following apparatus: a glass bell jar was cemented on a copper dish standing in a water-bath; the bell was connected with an air-pump and exhausted, and by means of a simple arrangement a drop of water was brought on to the plate. It was found that when the pressure was reduced two thirds more, the drop assumed the spheroidal state state at a temperature of 83° C.

THE SUPPLY OF GOLD FROM CALIFORNIA. — There has been a popular impression that the yield of gold in California is likely to become less and less, so that in a generation or so the ore may be exhausted. But if the gold is really going to "give out," there are few signs of it at present. So far, at least, as the deposits at the San Francisco Branch Mint are an evidence, the yield is actually and largely increasing. These deposits for the first eight months of 1870 have been: of gold, 719,211 ounces, against 532,686 ounces in 1869, and 398,081 ounces in 1867. The silver deposits in the same time have been 209,104 ounces, against 99,661 ounces for last year. This is inverting the usual experience of auriferous districts in favor of a region which must certainly, in material respects, be considered the most fortunate in the world.

ELECTRIC LIGHT. — In some experiments made at St. Petersburg it was found that by aid of an electric light, a target at 1660 yards was so well illuminated that, with an ordinary field-piece, the balls could be invariably lodged as truly as in daylight. Objects at some distance, on either side of the target, were also rendered clearly visible.

BOTTLING SUNBEAMS. — We find the following in one of our English scientific exchanges, but we doubt whether it will really prove to be an improvement upon the process for the extraction of sunbeams from cucumbers, mentioned by that veracious traveller, Lemuel Gulliver: —

"According to the *Echo Rochelais*, a professor residing in the Charente Inférieure has invented a method of bottling sunbeams, which can be used for various purposes when the sun is obscured by clouds — at least, so the professor thinks. His *modus operandi* consists in exposing a vase to the full effects of the summer sun, and corking it at the proper time. When required for use, he inserts a lens in the cork, and, if his statement is to be believed, has succeeded in lighting a candle by means of 'bottled sunbeams.'"

ATOMS.

AMONG the attractions advertised for the season, at the Crystal Palace, Sydenham, are a Cat Show (the first ever held, it is said), for the 13th of July; and a great "Pigeon Concours," after the Continental fashion, on June 26th, when 1,000 pigeons, of the same breed as those employed in the late war (and some of them the identical birds), will be let loose to race for prizes to various stations in Belgium. — The census of London, taken this year, shows a population of 3,251,804, an increase of 447,815 over that of 1861; but, on account of the great increase of railway facilities, a much larger proportion of the inhabitants of the city (that is, those whose occupation is urban), have their homes in the country than was the case ten years ago; and as the census includes only the people *actually in the city* at midnight on Sunday, April 2d, a large number who take advantage of cheap excursion trains to spend Sunday in the country were "counted out." — The new section of the Museum of Comparative Zoölogy, at Cambridge (profanely designated by certain members of the Legislature as "Professor Agassiz's Bug Palace") is rapidly approaching completion, and will more than double the present capacity of the building. — A block of granite, weighing seven tons, recently taken out at Westerly, R. I., will measure seventeen feet square after being dressed, and is to be used for the basin of a fountain in Central Park, New York. — The *Toledo Blade* remarks that "non-explosive" lamps and burning fluids are generally found to differ from others chiefly in the malignant and unexpected manner in which they explode. — At Birmingham (England), a rope has been made, which is more than six miles long, and weighs more than sixty tons. — The *Maine Journal of Education*, under the editorship of Mr. A. P. Stone, is one of the best magazines of its class. — It is said that new books by Huxley, Tyndall, Darwin, and Proctor, are as much in demand at English circulating libraries as the productions of the leading "sensation novelists" of the day. — Dr. Thudichum, in a lecture on wines, at the Society of Arts, introduced a new wine which had been made from *tea*, and which he commended as a good stomachic, likely to be useful in ordinary diet, and also in medicine. — The increase in the number of iron steamships for river navigation in Great Britain has been so great within the last few years, that sailing vessels on the streams there are likely ere long to become as rare as stage coaches in the streets. — The *Illustrated Price Current*, published by Messrs. Perry & Co., 37 Red Lion Square, London, gives as much good reading for a sixpence as any monthly magazine in England, published at the same price. — A recent English statute makes it illegal to advertise that if stolen property be returned, no "questions will be asked."

— The little kingdom of Belgium buys more British produce and manufactures than Prussia does, the amount for the last year having been £3,992,722 against £3,231,403; while France purchased £11,659,933 worth from John Bull's shop. — The Dominion of Canada, with a population of nearly four millions, supports thirty-seven daily papers, while the Australasian islands, with somewhat less than half the population, maintain thirty-five dailies. — A ladies' paper, the *Frauen Zeitung*, devoted to "education, housekeeping, domestic medicine, cooking, and light literature," has been started at Munich. — It is a singular fact that, with all the improvements in navigation, the number of shipwrecks in the British mercantile marine is increasing (that is, there are more in proportion to the amount of tonnage afloat than there used to be); the number in 1869 being about *fifty per cent.* more than in 1864, while collisions were about thirty per cent. more, and other casualties nearly sixty per cent. — It is an interesting question in meteorological zoölogy whether "sun-dogs" belong to the breed of Skye terriers. — Oiling the points of nails will save "elbow grease," in driving them into hard wood. — The philosophy of taking care of furniture is thus concisely summed up by *The Technologist*: "Keep water away from everything porous, alcohol from varnish, and acids from marble."

LITERARY NOTES.

The Appletons have just published their *Annual Cyclopædia*, for 1870. It is the tenth of these useful year-books, and one of the most valuable of the series, containing, as it does, a full account of the German-French War, and the tabulated results of the United States Census, so far as they can be given at present, in addition to the usual summary of political, scientific, industrial, and other intelligence for the year. It is illustrated with maps, and steel portraits of Gen. R. E. Lee, Count Von Moltke, and Victor Emmanuel.

The same house has reprinted Tyndall's *Fragments of Science for Unscientific People*, which include the famous lectures on the Scientific Use of the Imagination, on Dust and Disease, and on Radiation, with the fine tribute to Faraday, and some dozen other papers longer or shorter. The author says in his preface: "From America the impulse came which induced me to gather these 'Fragments' together, and to my friends in the United States I dedicate them."

The Harpers have issued *Light*, the second volume of Abbott's series of "Science for the Young." If the forthcoming volumes are equal to the first two, they will form by far the best juvenile library of natural science that has appeared on either side of the Atlantic.

Classical scholars will welcome the translation of *Livy*, which the Harpers have just added to their standard series of such works, and the edition of *Sophocles*, which, after an interval too long, adds another volume to their "Greek and Latin Texts." The cheap edition of Miss Muloch's works will be welcome to thousands, and the first instalment of *Lord Brougham's Autobiography* will make the reader impatient for those that are to follow.

The interesting papers on *The Eye in Health and Disease*, contributed by Dr. B. Joy Jeffries to "Good Health," have been published in a neat volume by Mr. Alexander Moore, of Boston. The author, in revising them for publication in this form, has made several additions, which increase their practical value.

Messrs. Hurd and Houghton publish *Wake-Robin*, by John Burroughs. The author says it is meant as "an invitation to the study of ornithology," and it is admirably adapted to awaken an interest in this branch of natural history. "Wake-Robin" is the common name of a flower, the white *Trillium*, whose blooming marks the vernal advent of the birds; and it was a "happy thought" to take it for the title of this charming little book.

OUR SCIENTIFIC AND MEDICAL EXCHANGES.

The *American Journal of Science and Arts*, for June, contains articles on Jupiter and his Satellites, by Maria Mitchell; on the Physical Constitution of the Sun, by Prof. Norton; on some New Analytical Methods, by T. M. Chatard; on the Oil-bearing Limestone of Chicago, by T. S. Hunt; on the Geology of the Delta of the Mississippi, by E. W. Hilgard; on Certain Forms of the Electrical Discharge in Air, by A. W. Wright; and other valuable papers.

The *Journal of the Franklin Institute* has papers on the Use of Pulverized Fuel, by Lieut. C. E. Dutton; on a Ship Canal across Cape Cod, by J. P. Frizell, C. E.; Notes on Crystallography (illustrated), by Prof. Wahl; on Pennsylvania's Foundation Stones, by Prof. Leeds; on a New Connection for the Induction Coil, by Prof. Houston; on Hydraulic Mortar, by Dr. Michaëlis; and many minor articles of great interest.

The *New York Medical Journal* has the following original communications: I. On the Physiological Effects of Severe and Protracted Muscular Exercise; with especial Reference to the Influence of Exercise upon the Excretion of Nitrogen, by Austin Flint, Jr., M. D.; II. On the Use of the Plaster-of-Paris Bandage in the Treatment of Fracture, especially Fracture of the Femur, by Henry B. Sands, M. D.; III. The Causes and Treatment of Œdema of the Lungs, by Thomas K. Cruse, M. D.; IV. A Plea for Bloodletting, by D. S. H. Smith, M. D.

The *American Practitioner* has original papers on Rupture of the Cervix Uteri occurring at the time of Parturition, by W. H. Newman, M. D.; Remarks on Chronic Rheumatism, by C. F. Ulrich, M. D.; Chloroform as an Internal Remedy, by A. P. Merrill, M. D.; Carbolic Acid in the Treatment of Intermittent Fever, by Dr. Freulich, of Melnik; Foreign Correspondence — Craniotomy, by M. Rhorer, M. D.

The *American Journal of Obstetrics* will hereafter be published by Messrs. Wm. Baldwin & Co., 21 Park Row, New York. The subscription price is $5.00 per annum, and our medical readers will bear in mind that we furnish it *with the* Journal at that price.

☞ The "Answers to Correspondents" are unavoidably laid over to our next number.

Medicine.

TABLE FOR THE EXAMINATION OF URINARY CALCULI.

By J. Campbell Brown, D. Sc., London, Lecturer on Chemistry and Toxicology at the Royal Infirmary School of Medicine.

1. Heat a portion of the powdered calculus upon platinum foil.

Destroyed.
(*a*) *Uric acid: Ammonic urate: Cystine: Cholesterine: Bile-pigment.*
(*b*) Uric acid from *Calcic and Sodic urates.* Ammonia from *Triple Phosphate.* Oxalic acid from *Calcic oxalate.*

Not destroyed.
(*c*) *Calcic Phosphate: Calcic Carbonate.*
(*d*) Calcic Carbonate from *Calcic Oxalate and Urate.* Sodic Carbonate from *Sodic Urate.* Magnesic Phosphate from *Triple Phosphate.*

If it chars and gives odor of burnt feathers, add to another portion a drop of concentrated nitric acid, and evaporate to dryness: pink color; cool, and add ammonia: purple color; *Uric acid* or *Urates.* If the odor is peculiarly disagreeable, resembling carbonic disulphide, dissolve in ammonia, and allow the solution to evaporate spontaneously; microscopic six-sided plates indicate *Cystine.* Mix another portion with lime; ammonia may be evolved from the *Urate* or *Triple Phosphate.*

2. Ignite another portion in the blowpipe flame until it burns entirely away (Class (*a*), see above), or leaves a white residue. If it fuses, it consists of a mixture of *Calcic* and *Ammonio-magnesic Phosphates.* Place a portion of the residue on red litmus-paper, and moisten with a drop of water; alkaline reaction indicates *Soda* or *Lime* from Class (*d*) or from *Calcic Carbonate.* Dissolve the rest of the residue in water, and filter. If the filtrate is alkaline, add a drop of hydrochloric acid and evaporate cautiously to dryness; microscopical cubical crystals prove the presence of *Sodium.* Dissolve the residue, insoluble in water, with hydrochloric acid, observing whether or not any effervescence due to carbonic acid takes place; add a comparatively large quantity of ammonic nitro-molybdate, and heat; a yellow precipitate indicates *Phosphoric Acid.*

3. Boil a portion of the powdered calculus in dilute hydrochloric acid; effervescence indicates calcic carbonate; filter; neutralize the solution by ammonia, and add acetic acid in excess; a turbidity indicates *Calcic Oxalate.* To the clear solution (or the filtrate if calcic oxalate is present) add ammonic oxalate; a precipitate indicates *Calcium, which was not previously in the state of oxalate;* filter, if necessary; add ammonia, and stir; a white crystalline precipitate indicates *Magnesic Phosphate.*

4. Biliary Calculi. *Cholesterine* is soluble in boiling alcohol, in ether, or in benzole; and, upon the spontaneous evaporation of the solution, is deposited in rhombic nacreous laminæ, which polarize light.

Bile pigment is insoluble in ether; soluble in potassic hydrate, and, when treated with nitric acid, becomes first green, then blue, passing into violet, red, and yellow.

Remarks. — We should modify the above somewhat for the detection of the inorganic constituents. For the detection of sodium or calcium the spectroscope should be used; or if that is not at hand, a little of the substance when mixed with alcohol will impart the characteristic yellow tint to the flame of the ignited alcohol, if sodium is present. For phosphorus, Bunsen's test surpasses all others. For this, take a piece of magnesium wire about a quarter of an inch in length, and place it in a small tube drawn from hard glass; the tube being about an inch long, and its diameter about three times that of the wire. Put a little of the finely powdered substance on the wire, and heat before the blowpipe until the wire takes fire. If the ignited tube be crushed with a drop of water in a watch glass the characteristic odor of hydric phosphide is at once perceived.

INFLUENCE OF ATHLETIC SPORTS ON HEALTH.

Dr. Farquharson read a paper on this subject before the Medical Society of London. Exercise, he contended, was necessary not only to preserve the balance between body and mind, but to promote the functions. It might, however, be potent either for good or evil; and damage was often done by persons of sedentary habits indulging, without due preparation, in such exertions. Dr. Richardson had, in the "Social Science Review," drawn attention to the dangers of volunteering in this relation. The nervous system had, even in repose, a heavy strain to bear; and if to this any sudden addition were made, the destructive processes were apt to exceed those of repair. The influence of the mind was, however, necessary for beneficial exercise; and athletics seemed best to supply this combination. The Germans, French, and Americans were behind us in this respect. Dr. Farquharson then showed that muscular degeneration was the result of excessive, as well as of deficient work. It was not likely that such results would follow our present system of sports; but there was reason to fear the danger of their being carried too far in our public schools, and thus checking mental progress, and dulling the clearness and sharpness of the brain. He next referred to the sports in detail. Rowing had been condemned by Mr. Skey and Dr. Richardson; but Dr. Farquharson endeavored to show that, from the great care exercised in picking and training crews, boating was less dangerous than these eminent authorities supposed. Gymnastics must be cautiously used when the frame was consolidated. Our public school boys or university men required valuable moral as well as physical training. It was argued that if the education of girls was eventually to be assimilated to that of men, they must also graduate in manly sports. In the treatment of the insane, active employment was most beneficial. An interesting letter from Dr. Langdon Down was read, showing the remarkable results which he had obtained with idiots at Earlswood Asylum. As regarded the proper dose of exercise, every one must be his own physician under ordinary circumstances; but

F quharson believed that he had seen cases of i table heart improved by a moderate amount, and q ted a case by Dr. Stokes in which relief from v ent cardiac dyspnœa was only obtained by run- n g. While serving in the Coldstream Guards, he h met with several cases of dilated heart in re- c its, from over-exertion. He condemned running; c ket he considered harmless. As to football, Dr. F quharson's experience had been derived from R gby; and although the game was apparently p ed there with great violence, an accurate list o the casualties during the past two years showed t it was comparatively harmless. One case of se ous injury to the spine had occurred, and steps w e taken to remove the apparently objectionable f ures of the game. It was not unreasonable to s pose that, although permanently serious results did n often follow that game of football in which the b was carried by the player, necessitating falls on th head and injury to the spine, the sharpness and c rness of the mind must be blunted; and he q ed the opinion of an eminent educational au- th ity to this effect.

SUPRA-ORBITAL NEURALGIA.

LLOW me to contribute a few lines to the JOUR- N in regard to Supra-Orbital Neuralgia. I have h many patients afflicted with a severe pain over o eye, sometimes over the whole of the forehead. T patients complain of a *sun* pain, as they most u lly term it, the pain beginning about the rising of e sun and subsiding about sundown, and also be g most severe on a clear bright day. On ex- a ination I find pain and tenderness on making pr sure in the supra-orbital notch. This soreness is vidence of inflammation in the course of the su a-orbital nerve, and is so severe that I have had tw patients who had to shade the eye for three days fr any light.

find a specific almost (if there are any specifics) in e hypodermic injection of morphine. I always ta about ¼ grain of morph. sulphate, pinch up a d of the skin just where the nerve makes its pa age over the supra-orbital ridge, and inject the sol ion well under the integument, withdraw the in ument and slip the finger over the puncture, re n it a minute or two and not a drop of blood wi be lost. The pain is very little and the relief is stantaneous, and no return of the complaint has oc rred.

J. W. FOSTER, M. D.

AMDEN, Mo.

MEDICAL MEMORANDA.

ONVICTS AS NURSES. — We find the following in late number of the *Pall Mall Gazette*, sent us by friend in England: —

Now that the question of the employment of co ict labor in works of public utility is again a su ect of discussion, it may be interesting to those w are anxious to devise some scheme for carrying ou his object to point out that in 1793, when the ye w fever was raging at Philadelphia, the convicts w employed with great success as nurses and at- te ants for the sick at Bush Hill Hospital. As th was great difficulty in finding persons who w d undertake this duty, recourse was had to the pr n, the convicts being fully warned of the dan- ge they would incur if they volunteered for the se ce. Nevertheless, as many offered as were w ted, and moreover continued faithful to their tr until the epidemic had ceased, without making a demand to be remunerated for their services. O man, committed for a burglary, who had seven ye s to serve, observed, when the request was m e to him to act as attendant at the hos- pi , that having offended society, he would be h y to render it some services for the injury. H went to the hospital, nor ever left it but once, and then by permission to obtain some articles in the city. His conduct was so good that he was made a deputy steward, and after receiving extra compensation, at his discharge married one of the nurses. The women convicts also behaved equally well, and when requested to give up their bedsteads for the use of the sick at the hospital, they cheerfully offered even their bedding. When a similar request was made to the debtors they all refused."

A SINGULAR MISTAKE. — Our readers have doubtless seen the accounts of the investigations made by the French Communists at the convent of Picpus, and the discovery of sundry strange-looking instruments of torture — "steel collars, iron corsets, and skull-caps, a rack turned by cog-wheels," and the like. But a correspondent of the *British Medical Journal* quotes the testimony of the "best known orthopedic mechanist in the country," to the effect that "he has not the slightest doubt that the nuns spoke with perfect truth in describing what were supposed to be instruments of torture as orthopedic appliances." The corset, the skull-cap, and the rack are beyond doubt instruments for the treatment of torticollis and spinal curvature, and would be recognized as such by persons familiar with the antique methods of orthopedy. The authority above quoted adds that he has for some time attended the convent establishments of London when their inmates needed mechanical aid.

POISONOUS GLOVES. — A correspondent of the *Medical Press and Circular* (English) states that a patient of his, a lady, purchased a box of green colored gloves, at a well-known and respectable house. In none of the gloves was the dye permanent, for upon the hand becoming heated it was stained to such a degree that warm water would scarcely remove it. After wearing a few pairs — for the gloves rapidly became shabby — the lady noticed a vesicular eruption at the sides and roots of the nails. This vesication in a few days proceeded to ulceration. Under suitable remedies the rash disappeared, but upon resuming the wearing of the gloves, the mischief recommenced with renewed severity. A further examination of the gloves, and analysis of a solution prepared from them, proved the existence of an arsenical salt, which at once cleared up the mystery of the case, and the nature of the dye.

A ROYAL VICTIM OF POISONOUS HAIR DYE. — The King of Sweden has been trying to renew his youth with a certain "Vegetable Hair Restorer," and the result has been that his Majesty barely escaped with his life. A royal commission is now sitting (or was, a few weeks ago), at the recommendation of the King's physican, Dr. Hamberg, to pass judgment on the cosmetic, which has been shown to contain the large proportion of lead usually found in these popular "vegetable" preparations.

AN ENGLISH PRESCRIPTION. — *The London Chemist and Druggist* gives the following among other recipes furnished by a "travelling doctor" to one of his patients: —

"℞ C. E. of Sarsaparilla . . . . fl. ℥vi.
Iiodroide of Potassum . . . fl. ʒi.

N. B. The above to be prepared by the chemist.

Q. S. Cochl parvum Magnum Mediocre."

The last line is particularly rich.

EMULSION OF ALMONDS. — The *Journal of Pharmacy* gives the following recipe for this useful preparation: —

Take sweet almonds (blanched), sugar, and glycerine (C. P.), of each 1 ounce; powdered gum arabic, 1 drachm; water, 2 ounces. Rub to a uniform paste, strain through muslin, and evaporate, by a heat not exceeding 150° F., to the consistence of a fresh solid extract; preserve in wide-mouthed bottles, of size convenient for use; may be flavored to suit taste. The author prefers orange-flower water and oil of almonds. When an emulsion of almonds is prescribed, as is now often the case, as a vehicle for chloral hydrate, it is readily prepared as follows: Take concentrated emulsion, 2 drachms; water, sufficient to make 1 ounce of mixture; mix thoroughly. The above emulsion is preserved, or rather condensed, milk of almonds, and may be useful for dietetic and culinary purposes, — as, for instance, to prepare readily orgeade. The *syrop d'orgeade* does not, as is well known, keep for any length of time without fermenting and spoiling.

SULPHATE OF QUININE IN THE TREATMENT OF SPONTANEOUS ERYSIPELAS OF THE FACE. — According to Dr. Perroud, the sulphate of quinine, administered in moderate and fractional doses, promptly arrests the march of non-traumatic erysipelas of the face, and removes it wholly, in most instances, on the second or third day of its administration. The effects of this medicinal agent are less evident in wandering erysipelas, and in those attacks which appear under the influence of constitutional states, as, for example, rheumatism. The researches of modern microscopists on the diffusion of leucocytes lead one to think that it is through its opposition to this diffusion that sulphate of quinine acts upon erysipelas.

M. Perroud gives daily from thirty to forty centigrammes of quinine in a simple solution, of which a teaspoonful is to be taken every half-hour, so as to keep the patient under the persistent and prolonged influence of the remedy.

LOCAL APPLICATIONS TO BURNS. — Dr. Binkerd recommends as an application to burns, when first seen, carbolic acid and glycerine, in the proportion of from five to ten drops of the former thoroughly incorporated with two ounces of the latter, spread on with a camel's-hair or other light brush, then a layer of white cotton, over which a roller-bandage is neatly adjusted. For the suppuration following burns he recommends the following dressing: Yellow wax, melted and strained, ℥j.; raw linseed-oil, ʒiij.; tannin, ʒj.; subnitrate of bismuth, gr. xx. The wax must be first melted, the oil then added, and the whole stirred until incorporated; next, the tannin is added, and lastly the bismuth. The ointment should be applied on pieces of lint.

BOILING WATER BLISTER. — A boiling water blister may afford a most powerful, ready, and useful stimulus to the nervous system. A basin, say half-a-pint, should be filled with flannel, hastily pressed in, and boiling water poured upon it to saturation; a plate or large saucer should be applied to its top, and, being inserted, the superfluous water can be forced out of it, the saucer removed, and the basin pressed upon the chest or elsewhere; a soft towel round the edge guarding the neighboring parts — of course, it must not remain on long.

VALUABLE FORMULÆ.

APERIENT SOLUTION. — Dr. Mettauer recommends the following: —

℞ Aloes Socot. . . . . . . ℥iiss.
Supercarb. Sodæ . . . . . . ℥vi.
Water . . . . Oiv.
Spirit Lavend. Comp. . . . . f. ℥ii.

Digest 14 days and filter. Age improves the quality and taste. It is used in weak digestion, with costive habits, dyspepsia, etc.

GARGLE FOR ULCERATION OF THE TONSILS. —

℞ Zinci Sulphat.
Chlorat. Potass aa . . . . . . ʒii.
Sage Tea . . . . ℥viii. M.

S. — Gargle the throat frequently. This is an excellent wash in ulcerations of the tonsils, or aphthous affections of the mouth.

AN EXCELLENT DINNER PILL. —

℞ Pulv. Capsic . . . . . . ʒi.
Pulv. Rhei . . . . . . ʒiss.
Ext. Gentian . . . . . . ʒi. M.

Make pills 60. S. — Take two or three every day before dinner.

Sulphur Pills. — The following formulæ, which we take from the *Druggists' Circular*, furnish a convenient and neat method of administering sulphur as an alterative in chronic rheumatism and certain diseases of the skin: —

1. Take Sulphur . . . . . 42 grains.
   Castile Soap . . . . . . 18 "

Mix, and divide into 12 pills. One to three pills for a dose, morning and night.

2. Take Sulphur, Acetate of potash } of each . 24 grains.
   Confection of roses, q. s. for 12 pills.

One to two twice a day in scorbutic and scrofulous patients, and when sulphur generally is indicated.

Glycerine Ointment. —

℞ Starch . . . . 3 parts,
Glycerine . . . . 10 "

The starch, finely pulverized, is digested for about an hour with the glycerine at the heat of a water-bath.

DEATH OF AN ECCENTRIC CHARACTER.

William Sheldon, who died at Longmeadow, Tuesday, the 23d, at the venerable age of 83, was the son and only child of Dr. Sheldon, a leading physician and highly esteemed citizen of Springfield, in the olden time. After his father's decease, his fond mother brought him to Longmeadow, and assiduously devoted her remaining days to that tender and indulgent care which, conspiring with his natural idiosyncracies, developed a life so original and singular as to demand an obituary. An ample income exempted him from labor, and gave him leisure to cultivate his oddities. College was too rough for him, and so interfered with his health and independence, that he came home after a short experience, to the maternal embrace. In his budding authorship, he wrote novelettes for the old *Springfield Gazette*, and in the maturity of his powers at Longmeadow, he published scientific and theological works, but too profound for his age. He understood all mysteries, and explained the "spirit rapping" and the "seventh vial." He felt a sublime contempt for the world's ignorance and fatuity, and the fullest assurance that after his decease, its wiser second thought would raise him to a celebrity level with that of Moses, Mohammed, or Sir Isaac Newton.

He was a daily opium-eater for fifty years, and measured his food with scrupulous accuracy. He walked a given number of miles each day at precise hours, traversing the same well-worn footpaths, and measuring carefully his halls and attics for his rainy-day constitutionals. He utterly eschewed carpets and paper hangings as productive of disease, hated house cleanings even worse than common men, but delighted in an open wood fire and Blackwood's Magazine. He was kind to the poor, even to the suffering of much unrighteous imposition from unprincipled tramps. Always exceedingly gallant and chivalrous toward women, and extending freely the hospitalities of his bachelor home to his friends, he was autocratic and imperious in his domestic rule. He believed in woman's rights to wait and serve both before and after his indulgent mother's death, and yet never toward mother or servant was there a kinder son or master, never a more correct and upright and honorable man in all his social relations. Many will miss the old man from his accustomed haunts, —

"Along the heath and near his favorite tree,"

And a few, casting back long memories, will mourn for him.

Large tracts of lands in New Jersey are devoted to the cultivation of peppermint, bergamot, and wintergreen for their oil, used in making perfumes and toilet soaps.

PHOSPHORUS ESSENTIAL TO FUNGOID GROWTH.

Prof. Frankland has presented a paper to the London Chemical Society on the "Development of Fungi in Potable Waters." It had been previously shown that the addition of sugar to water contaminated with sewage, caused a kind of fermentation, followed by a rich fungoid growth. Prof. F. obtained similar results, but in the course of his researches he encountered some reactions which revealed to him that the presence of sewage matter in saccharic water is in itself not sufficient to produce fungoid growth, but that the presence of phosphates in some form is indispensable to such production. From all his observations he drew the following conclusions: 1. Potable waters, mixed with sewage, urine, albumen, and certain other matters, or brought into contact with animal charcoal, subsequently develop fungoid growth, and other organisms, when small quantities of sugar are dissolved in them, and they are exposed to a summer temperature. 2. The germs of these organisms are present in the atmosphere, and every water contains them after momentary contact with the air. 3. The development of these germs cannot take place without the presence of phosphoric acid, or a phosphate, or phosphorus in some form of combination. Water, however much contaminated, if free from phosphorus, does not produce them.

HOW TO GIVE CHILDREN AN APPETITE.

Give children an abundance of out-door exercise, fun, and frolic; make them regular in their habits, and feed them only upon plain, nourishing food, and they will seldom, if ever, complain of a lack of appetite. But keep them overtasked in school, confined closely to the house the rest of the time, frowning down every attempt at play; feed them upon rich or high seasoned food, candies, nuts, etc., allow them to eat between meals and late in the evening, and you need not expect them to have good appetites. On the contrary, you may expect they will be pale, weak, and sickly.

Don't cram them with food when they don't want, or have no appetite for it — such a course is slow murder. If they have no appetites, encourage, and if need be, command them to take exercise in the open air. Don't allow them to study too much, and especially keep them from reading the exciting light literature which so much abounds in our book-stores and circulating libraries. In addition to securing exercise for the children as above, change their diet somewhat; especially if they have been eating fine flour, change to coarse or Graham flour.

CONSERVATIVE SURGERY.

Probably in nothing is the progress of medicine more apparent than in the gradual abandonment of those heroic methods of practice which were once the glory, but happily have now come to be the shame, of the profession. As science widens the practitioner's knowledge of nature's methods, it at the same time plainly declares the limits of his power, and thus both physicians and surgeons are being brought to see that the process of healing is after all more a matter of time and external conditions, and less a question of drugs and dogmatic interference. The experiences of medical men during our recent war go far to confirm this. Where before the knife had been unsparingly employed — often to the sacrifice of life as well as limb — and dosing was the rule and healthy conditions the rare exception, it was found that less cutting and more care, fewer drugs and better sanitary conditions, gave greatly improved results. Injuries of certain parts, and particularly of the knee-joint, are, however, still held by many to demand the most radical measures in their treatment. But even these turn out be amenable to the saving influences of nature. Dr. Langenbeck, an eminent German surgeon, has put forth the opinion, in opposition to much authority, that injuries of this part, unless involving an extreme degree of disorganization, may be treated with a view to the preservation of the limb; and he fortifies this by citing the fact that out of eighteen cases of this nature under his observation, fourteen recovered. — *The Galaxy.*

WHAT SICKNESS COSTS.

The *Medical and Surgical Reporter* estimates the cost to the people of the United States, of medical services and medicines, at $100,000,000, and $25,000,000 for the quack medicines swallowed. "Let the people," it says, "study these figures awhile, and then reflect that probably one half, or certainly a large fraction, of this expense is incurred by a deliberate infraction of the laws of health; that, if they tippled less, smoked less, overworked less, were less 'fast' and less self-indulgent, they would save some thirty or forty millions a year."

If the cost of the loss of time, loss of happiness, loss of ability to do and dare, was added to the above, there would be no counting the expense of sickness. And then add to this the expense of those indulgences that make us sick.

The truth is, sickness is the most expensive nuisance on the face of the globe. There may be instances where it makes people better, but generally it makes people selfish, sad, misanthropic, nervous, mean, and miserable. The best way to make ourselves happy and good is to keep ourselves well.

Test for Purity of Wines. — The adulteration of wines is readily detected by the microscope. All wines that did not obtain their color through the process of fermentation can be thus proved to be artificial. The natural wine (after evaporating a drop) shows a homogeneous color; the artificial shows small colored globules, differing with the substances used for coloring the liquid.

Anæsthetic Property of Carbolic Acid. — Mr. E. Wilson (*Journal of Cutaneous Medicine*) asserts that carbolic acid has a striking anæsthetic power. "I employ it," he writes, "at present very commonly, previous to the application of caustic to *lupus and epithelioma*. It benumbs the surface, it dulls the excessive sensibility of the superficial nerves, and it thereby permits the caustic application of our remedies with a great reduction in the amount of pain."

Old Dr. Heim, of Berlin, was as original and eccentric as he was celebrated. He used to treat annually as many as 3,000 poor people; but, on the other hand, he demanded liberal fees and respectful treatment from great people. One day the Palatine of Hesse, while on a visit to Berlin, went to consult him. Seeing that the Prince remained seated when he entered, Heim said, abruptly, "Would your Highness please to stand up for a moment?" The astonished patient did as he was bid. "So, it will do; now please to turn about once." This having been done, he remarked, with a musing air of manner, and in a leisurely tone, "Hum! not as stiff as I should have expected a Palatine to be!"

A man stepped into a drug store in Corydon (Ind.) the other day and wanted to buy a "tink's violin," to cure a certain malady. He said the doctor told him to get it. After a vast amount of cogitation and questioning, it was found that the man wanted tincture of iodine.

Familiar Science.

AMONG THE COAL MINERS.

HERE is no more picturesque or interesting re..n of country in the United States, than that n hich are found the anthracite coal-beds of Pe sylvania. In many respects it is more at- ra ive than the mountain regions of New H. pshire, or the Adirondacks of New York, n it is equally accessible. Upon entering this eg on from New York, by way of the New e y Central Railroad, the first remarkable oi reached is the town of Mauch Chunk, a a which few dare attempt to pronounce with- ut irst taking lessons in the feat from some one f e residents of the place. Correctly inter- re d, it means "Bear Mountain," an Indian a for a lofty peak ascending from the valley. I ch Chunk lies in a narrow gorge between n mong high hills or mountains. This gorge ite narrow, and the scenery is wild and ra. The little Lehigh River, arrested in its o e by dams, canal locks, and rocks, foams and re on its way through the defile, and the cr m of steam whistles, the rumbling of innu- e ble trains of cars, and the shouts of boatmen, a up a chorus of noises, day and night, alto- et r unusual. The town is so wedged in by e ills that only one narrow street is practica- le nd the whole space is taken up by the a d river, the canal, railroads, street, and line f uses. No place on earth presents so many te sting and wonderful points connected with e bal interests, as Mauch Chunk. Standing p the balcony of the hotel, and looking out p the mountains, they seem to be alive with n rains of coal cars. These are not confined valley, but are seen far up the sides of the o ains, and upon their very tops, at an alti- d of twelve and fifteen hundred feet. They o along, looking like huge serpents, winding o d among rocks and trees, and by deep a s, and over trestle-work supports, carrying e heavy loads of black diamonds to the wait- g rs and boats below. The trains not only n ong upon horizontal pathways, but up and w the mountains, upon inclines which seem perpendicular. At the highest points are stationary engines which draw up the long ai of empty cars with the greatest despatch.

T starting-point of what is known as the S ch Back" railroad, is at Mauch Chunk, a most unique and wonderful road it is. It as ot designed for passenger travel, but solely e conveyance of coal from the mountain about nine miles from the town. An en- r ing gentleman some time ago obtained r sion of the owners to run an excursion ver the road twice a day; and parties are aken over the route in comfortable little ithout locomotives or driving power of any To reach the road proper, it is necessary nd to the top of Mount Pisgah, a precipitous dome in front of the hotel upon the opposite side of the river, and which is about thirteen hundred feet high. We take an omnibus, which carries us up four hundred feet to a niche in the mountain, and here stepping into the car we are drawn up an ascent at an angle of 45° to the top of Pisgah, nine hundred feet higher. On the very apex of the mountain the stationary engine is placed, with two huge smoking chimneys which give to the mountain the appearance of a volcano. We started from this elevation on one of the loveliest mornings in June, to make the circuit of the "Switch Back," or what is sometimes more properly called the "Gravity Road," and this carries us over an extent of twenty-five miles upon the tops and sides of mountain ranges. Our first stage is down a gentle decline of nine miles to the foot of Mount Jefferson, up which we are drawn by another stationary engine. The way is now a downward grade until we reach Summit Hill, when we descend rapidly into the valley, where most of the coal mines in working condition are found. This is a sequestered, romantic place, apparently as far out of the world as any one would ever desire to visit. The great coal breakers are upon the right hand and the left; and dark, yawning pits, the entrances to the subterranean passages traversed by the coal diggers, are seen in every direction. Mountains of coal dust, the refuse of the breakers, project into the valley, and give a sombre hue to everything. Even the leaves upon the trees become darkened by the coal dust; and black, turbid streams wind around among the rocks, seeming anxious to escape from the dingy caverns in which they originate. From the "slopes" or entrances to the mines, mule teams attached to trains of cars, loaded with coal, are constantly emerging; and the drivers in charge, with oil lamps affixed to their caps, and begrimed with the sooty powder, seem like mountain imps who have no business with daylight or the outside world.

Before proceeding to speak further of mines and coal mining, let us return to the road by which we came into this region. Shortly after leaving the valley, another mountain opens before us with its smoking chimneys at the apex, and up this we are drawn at a rapid rate. From this high point our return route commences, and we run over the track at a fearful speed until we reach the town of Summit, the home of the miners, which has a church, school-houses, and barracks for troops, as it has been found necessary in turbulent times to quarter a regiment of soldiers at this point to preserve order. The track the whole way is a down grade, and an hour's ride brings us back to the base of Pisgah, our starting-point. During the ride of twenty-five miles we have been seated in our little car by the side of the conductor, whose sole business has been to keep his hands upon an iron wheel which controls the brakes, and governs our rate of speed. We look out of the open door in front and our view is unobstructed by engine or tender, for we travel independent of both; no smoke, gas, or steam whistle annoys us, and we rush along, propelled by an unseen power, a force which is potent, but inexplicable. It is impossible to realize the true nature of the track, for the descent is very gradual, and it appears like an ordinary level road, high up among the clouds. We presume the excursion is not peculiarly hazardous; but it must be confessed it seems so, at least during the first half dozen miles of travel; we could not learn that any serious accidents had occurred during the time the road has been open to excursionists, and it is probable that every precaution has been and will be used to prevent them. This railroad in many respects is as wonderful and more interesting than that constructed up the bare side of Mount Washington. The steep declivities are, however, surmounted by the aid of stationary engines at the tops, whilst the cars on the Mount Washington road are accompanied by the unique little locomotive, which lifts with its arms of iron behind, and forces the train up the almost perpendicular rock to a height of seven thousand feet. We can never cease to wonder at and admire such triumphs of mechanical and engineering skill.

A hunter named Ginter first discovered anthracite coal in this region, eighty years ago; but he did not understand its nature, and it was called "black stone," and supposed to be as incombustible as granite. The history of the early attempts to burn anthracite are not only amusing but instructive, as they serve to show how mankind may be baffled in attempts to reach an end as easy and simple as building an anthracite coal fire. It required more than *forty years* to learn how to burn this form of fuel; and it is alleged that the discovery was made accidentally after all. An experimenter in Philadelphia, after most persistent efforts to ignite the black stones, gave up in despair, and left his furnace filled with a mixture of wood and coal, and went home to dinner. Fortunately there were some sparks left upon the wood, and more fortunate still, the furnace door was left *closed*, with the draft *open*. This arrangement afforded the necessary "let alone" treatment, and the wood, soon igniting, heated the coal to a point where it also could be ignited; and as the downcast experimenter returned to rake out and throw away the supposed worthless coals, he found them to his surprise all aglow, and causing such intense heat that his furnace was well-nigh destroyed. This result of course dispelled the idea that anthracite was an incombustible substance; and soon companies were formed to work the mines. Coal was, however, brought from this region by slow and wearisome modes of conveyance, such as by wagons, and on mules' backs, until 1827, when an imperfect track was laid to run cars down the mountains by gravity, and in this originated the present very remarkable "Gravity Road."

But let us leave Mauch Chunk, and by the Lehigh and Susquehanna Railroad travel up the wild gorges of the mountains through which the Lehigh River forces its way, and when we have reached the summits, we will descend into the beautiful Valley of Wyoming. This broad, fertile basin, with the rim of mountains bounding it upon every side, is indeed a charming retreat; and no wonder the poor Indians in the early days of our history were reluctant to give it up to the rapacious white men. Here every inch of ground rests upon a support of anthracite, for the valley and surrounding hills are full of it, and it crops out at various points, showing what a wealth of the mineral reposes below. Scattered up and down the valley are seen the huge coal breakers, which dot the landscape almost as thickly as do the windmills in Holland. Coal, coal, nothing else but coal is thought of or talked about, and the pretty city of Wilkesbarre is the centre of the great industry. We are pleased to accept the kind invitation of Mr. J. H. Swoyer to visit the celebrated Enterprise Colliery, in Pleasant Valley, which is under his direction, and witness the operations of mining, crushing, screening, and preparing coal for the market. With Mr. Patten, the gentlemanly superintendent, for a guide, we descend the "slope" and penetrate into the side of the mountain, and grope our way through the grim passages made by the miners in order to reach the deep coal seams, hundreds of feet below the surface. Small cars, black as the coal itself with dust, rumble along the excavations, drawn by mules, conveying the coal to the great shaft over which is built the breaker, and here it is hoisted by steam power up to daylight. The reflection occurs that this remarkable substance, which is in itself only solidified sunlight, has rested in its dark abode for uncounted ages, and not a beam of light has shone upon it until to-day, since the floods of the carboniferous epoch swept it into these basins as vegetable matter, and covered it with the silt and mineral *débris* which were forced along with it in its course. We are led to regard it as a kind of *pemmican* fuel, and here is the vast *cachet* established by the Infinite One, from which we can draw unlimited supplies.

The Enterprise Company are at present working upon a seam a little less than five feet in thickness, which is about the least that can be worked with profit. The coal *in situ*, as we look upon it by the dim light of the miners' lamps, appears as a dark, shiny stratum, tightly compressed between heavy masses of shale and limestone. The weight of the mountain seems to rest upon it, holding it as in a vice. To dislodge or break it from its bed is the work of the experienced miner, and this is accomplished with wonderful tact and skill. A sharp drill is used, by which orifices are made in the seam, and when these are filled with gunpowder, tamped, and exploded, large fragments are dislodged, which are placed in the cars by the laborers, and drawn through the dark labyrinths to the shaft. The regular miner never lifts any coal for carriage; this is the work of the *laborer*, and entirely beneath his dignity. As we entered the mine at about noon, several miners were met coming out, and we were informed by the superintendent that they had completed their day's work, and had the afternoon to themselves. They had dislodged as much coal from the bed as the laborers could load and carry away during the day, and their task was completed. There is an aristocracy in these subterranean abodes as exclusive as any found above ground, and "consuming ambition" finds as full play in the breasts of the little sooty colliery boys, as in those met with in our schools or employed in our counting-rooms. The boys born of the men at the mines care but little about books, and dream of no other occupation than mining. At an early age they go into the breakers, and take their first step in the business in picking out the fragments of slate that fall through the meshes with the coal in the process of screening. From this they look forward with earnest desire to the time when they can go into the mines and drive the donkeys attached to the coal cars; from this they wish to become laborers, and load the coal; and the crowning summit of their ambition is only reached when they become miners, and are fully connected with the "ring," and under full pay.

The mines are filled with the smoke of gunpowder; but after a short stay it is not oppressive. The work of mining, viewed from our stand-point, is not an agreeable occupation, but it is less exacting and laborious than many other kinds of labor. It is also less hazardous than many other pursuits, although a contrary notion prevails. The perils incident to the sea are far greater; and also many industrial pursuits, such as the making of gunpowder, matches, pigments, etc., are more destructive to life than coal mining. There have never been in this country but two very serious casualties: that of the Avondale mine, and the recent one at Pittston. There are employed in the anthracite region about 30,000 miners, and the loss of life from accidents incident to the business shows but a very small percentage. It is the terrible *nature* of the casualties, when they do occur, that awakens such wide-spread sympathy, and causes the occupation to be looked upon with dread.

The masses of coal raised from the pits are carried far above the opening of the excavation and thrown into the breaker, a ponderous iron machine, which crushes them to fragments of various sizes; and then they fall into revolving cylindrical sieves, the meshes of which determine the size of the coal manufactured. In this manner, the "egg," "nut," and "bean" coal are separated, each sieve sifting out its appropriate size, and directing it into different receptacles. At some of the mines one thousand tons of coal are raised and broken in a day, and the aggregate of the amount produced is prodigious. The profits of the business, as conducted at the mines, seem reasonable, as we were informed by one of the largest producers that he was entirely satisfied when he could realize twenty-five cents profit on each ton delivered. A vast monopoly has virtual control of our anthracite coal-beds, and what the future may develop it is impossible to foretell. A comparatively few very wealthy men in our large cities are the owners of the mountains and valleys where lie hidden the precious deposits of coal, and upon them depend in a measure the development of our great national industries. At present it is not for the interests of owners to attempt to combine or monopolize, but how long this may continue is a question of no little national importance. The supply *is vast* in amount, practically inexhaustible, — and this fact affords reasonable assurance that centuries may elapse before any measures may be taken to force prices to a point where they will be restrictive, or very oppressive. The high prices of coal which have ruled during the past two or three years are caused by occurrences independent of ownership of the coal lands.

DREDGINGS FROM THE GULF STREAM.

A YEAR or two ago, Mr. Pourtalis, who has charge of the dredging carried on under the superintendence of the Coast Survey, presented us with some specimens of dredgings from the Gulf of Mexico.

They were only some small pieces of red and white rocks, a white clay which had been air-dried, and a piece of bone which the Cambridge zoölogists pronounced a part of the rib of the manatee or sea-cow. Yet the study of these relics has opened to us a very interesting field of investigation.

Our first inquiry was naturally into their chemical composition. This we found to be somewhat variable, depending of course on the nature of substances from which they were formed. The bone had changed but little beyond losing its organic matter, and acquiring some iron and a little more carbonate of lime. The ooze consisted mainly of calcic carbonate, with a little phosphate, a little silica, and some magnesia; while the other rocks varied between these two extremes. In order to understand these facts more fully, we procured, through the kindness of Mr. Pourtalis, and analyzed, a number of specimens of coral, and a piece of the recent bone of the manatee. We found that the coral consisted mainly of calcic carbonate with traces of calcic phosphate, and that the rib did not differ essentially from other bones.

Examination with the microscope showed that the silica contained in ooze was in the form of sponge spicules. We therefore had its formation and composition accounted for. As soon as any portion of coral reef dies or becomes injured in any way, old Ocean at once takes possession of it and grinds it into fine powder, which he deposits in his still depths, ready to form limestone rock. It is supposed by some geologists that all the limestone that exists in the form of rock has been submitted to this process.

But the manatee bones were yet unaccounted for. How did they get into the strait between Florida and Cuba, when their native place is one of the rivers of South America? The great oceanic current that sweeps around the north coast of South America and through the Gulf of Mexico, becoming as it emerges into the Atlantic the well known Gulf Stream, explained this to us. The dead bodies of the manatees would be carried down by the rivers and out to sea; there they would encounter this current, and be swept along by it, and gradually decaying would deposit their bones on the floor of the ocean. In some localities it is almost covered with them, every dredgeful bringing up numerous specimens. Another peculiarity of these dredgings may be mentioned in this connection. The main portion of the dredging was done in the track of the ocean steamers which run between the Gulf ports and the rest of the world, and the dredge was continually bringing up quantities of cinders that had been thrown overboard from these vessels.

Another question still remained unanswered in regard to these deposits: where did the ir

come from? In some of the rocks this seemed to be the cementing material, one of them containing as much as 20 per cent.

Analyses of sea water taken from the open ocean show that iron is almost entirely wanting in such water. But, on the other hand, iron is always found in the water of inland seas and rivers. We have been unable to find analyses of the water of the Gulf of Mexico, or of that of the rivers that empty into it, but reasoning from similar circumstances elsewhere we should say that the water of the Mississippi and other rivers emptying into the Gulf carried down considerable iron. This coming in contact with decaying organic matter, such as would be furnished by the *débris* of the coral, and by the decaying skeletons of the manatees, would be deposited as carbonate. Such a deposition is in fact going on at the bottom of many ponds. The carbonate is thus decomposed and changed into the sesquioxide. Having thus studied up these deposits, we were led to question as to the origin of the bone deposits of South Carolina. May they not have been formed at the bottom of the ocean in the same manner? They differ but little from these rocks, with the exception that they contain a large amount of sand; this may be regarded as purely adventitious, having been washed in from the surrounding sand-hills.

If the deposit at the bottom of the Gulf was elevated only six hundred feet, we should have a series of phosphate beds south of Florida in every way similar to the beds of South Carolina.

WHY CIRCLES PLEASE THE EYE.

PROF. MÜLLER, in a course of lectures in Berlin, offered a simple and mechanical explanation of the universal admiration bestowed on these curves. The eye is moved in its socket by six muscles, of which four are respectively employed to raise, depress, turn to the right, and to the left. The other two have an action contrary to one another, and roll the eye on its axis, or from the outside downward, and inside upward. When an object is presented for inspection, the first act is that of circuition, or going round the boundary lines, so as to bring consecutively every individual portion of the circumference upon the most delicate and sensitive portion of the retina. Now, if figures bounded by straight lines be presented for inspection, it is obvious that but two of these muscles can be called into action; and it is equally evident that in curves of circle or ellipse all must alternately be brought into action. The effect then is, that if two only be employed, as in rectilinear figures, those two have an undue share of labor; and by repeating the experiment frequently, as we do in childhood, the notion of tedium is instilled, and we form gradually a taste for straight lines, and are led to prefer the curves which supply a more general and equable share of work to the muscles.

THE SUNBEAM.

THE greatest of physical paradoxes is the sunbeam. It is the most potent and versatile force we have, and yet it behaves itself like the gentlest and most accommodating. Nothing can fall more softly or more silently upon the earth than the rays of our great luminary — not even the feathery flakes of snow which thread their way through the atmosphere as if they were too filmy to yield to the demands of gravity, like grosser things. The most delicate slip of gold-leaf, exposed as a target to the sun's shafts, is not stirred to the extent of a hair, though an infant's faintest breath would set it into tremulous motion. The tenderest of human organs — the apple of the eye — though pierced and buffeted each day by thousands of sunbeams, suffers no pain during the process, but rejoices in their sweetness, and blesses the useful light. Yet a few of those rays, insinuating themselves into a mass of iron, like the Britannia Tubular Bridge, will compel the closely-knit particles to separate, and will move the whole enormous fabric with as much ease as a giant would stir a straw. The play of those beams upon our sheets of water lifts up layer after layer into the atmosphere, and hoists whole rivers from their beds, only to drop them again in snows upon the hills, or in fattening showers upon the plains. Let but the air drink in a little more sunshine at one place than another, and out of it springs the tempest or the hurricane, which desolates a whole region in its lunatic wrath. The marvel is that a power which is capable of assuming such a diversity of forms, and of producing such stupendous results, should come to us in so gentle, so peaceful, and so unpretentious a guise.

HOUSEHOLD RECIPES.

LAUNDRY POLISH FOR LINEN. — Add to starch made in the usual way a small lump of white sugar, or a bit of white wax or spermaceti, or a few thin shavings of white soap and a teaspoonful of salt. After the clothes are rinsed in the blue water, starch them, and dry on the clothes-line; then wring them from cold water, roll up tightly, and let them lie awhile. Iron smoothly in the usual way. Then place the bosom, or piece to be polished, on a board with a single fold of muslin over it, pass a damp cloth over the linen and polish with an iron made for that purpose, such as may be bought at the hardware or kitchen furnishing stores.

SWEET PICKLES. — The following is a good recipe for making sweet pickles of peaches, tomatoes, apples, etc. For each nine pounds of fruit, take three pounds of sugar, one pint of vinegar, and one half ounce of cloves. Put the sugar and vinegar together in a preserving kettle, let them come to a boil, then put in cloves, ground if for apples; if for peaches or tomatoes, put two whole cloves in each, or more as you like. Put your fruit into the syrup, let it boil until it cracks open, then lift it out carefully, boil down the juice, and pour it over them. As the juice gets thinner by standing, drain it off, and boil it down as much as you can conveniently, pouring it over the fruit again.

CHOW-CHOW. — Chop fine two quarts of green tomatoes, two quarts of white onions, one dozen green peppers, one dozen green cucumbers, one large head of cabbage. Season with mustard and celery seed, to suit the taste. Cover with the best cider vinegar. Boil two hours slowly, stirring continually. As soon as you take it from the stove, add two tablespoonfuls of salad oil. Cover tight, and keep in a cool place.

CURRANT JELLY WITHOUT COOKING. — Press the juice from the currants, and strain it; to every pint put a pound of fine white sugar; mix them together until the sugar is dissolved; then put it in jars; seal them, and expose them to a hot sun for two or three days.

A GOOD HOME-MADE BEER. — Take two ounces of ground ginger, one ounce of cream of tartar, one and one half pounds of white sugar, and two lemons cut in thin slices and seeds taken out. Pour on these ingredients three gallons of boiling water; let it stand until quite cool; then stir well into it a coffee cup of brewer's yeast. In twenty-four hours it will be ready to bottle, and in thirty-six will be fit to drink, but is better in a week.

TONGUE TOAST. — Take cold boiled tongue, mince it fine, mix it with cream, and to every half pint of the mixture allow the well-beaten yolks of two eggs. Place over the fire, and let it simmer a minute or two. Have ready some nicely toasted bread; butter it, place it on a hot dish, and pour the mixture over. Send to table hot.

TO REMOVE WARTS. — Dissolve an ounce of white vitriol in five table-spoonfuls of water, put into a vial, and rub the warts three or four times a day, and oftener if convenient. In two weeks they will be gone, without pain or scar. Other remedies are to moisten the tops of the warts once a day with creosote; or burn a piece of linen or cotton on any piece of steel and rub the moisture left by the burning on the warts, repeating the operation three or four times.

THE WATER HAMMER. — Prof. Lommel has recently made some interesting experiments with the water hammer. By means of tin foil coatings he connected the ends of the hammer with the conductors of a Holtz electrical machine; on working the machine vivid flashes, resembling sheet lightning, passed from end to end of the tube. These flashes are of a brilliant red color, and on being examined with the spectroscope give the hydrogen and sodium lines. After a short time the vacuum is found to be destroyed by the gas set free, and the water has acquired an alkaline reaction from the decomposition of the glass. In tubes filled with dilute alcohol the discharge was of a light green color, and gave the lines observed in the lower portion of the flame of the Bunsen burner.

The tube of a thermometer, when connected with a coil or induction machine by means of tin foil on the ends, is seen to be filled with the green light given by mercury vapor, if the vacuum is perfect. If however a trace of air is present, the discharge is of a reddish color. This therefore gives a ready method of testing a thermometer.

BALLOON VOYAGING. — The siege of Paris by the Germans opened a new era in aerial navigation. It has served to demonstrate the entire feasibility of balloons as means of communication between the inhabitants of the place under seige and the outside world. There is no certain intelligence of any loss of life, and the dangers do not seem to be greater than those which attended navigation in its earlier days. The observed heights to which the balloons ascended were between 2,000 and 8,000 feet. The longest voyages taken were one of 420 miles to St. Baume, at the rate of 28 miles per hour, and one to Norway, at the rate of 55 miles per hour. By means of balloons Paris was enabled to communicate with the country about once in two days, but it is not known whether any attempts to reach the city by these means were successful.

CERTAIN colored rays of light are particularly favorable to the development in organic infusion of infusorial life, while other rays are more favorable for the production of microscopic forms of vegetable life. Thus, M. Pouchet says, *white* light is the best fitted for obtaining the former result, after which comes the *red* ray, then the *violet*, the *blue*, and finally the *green* ray. On the contrary, for the development of vegetable "proto-organisms," the *green* ray is the best fitted; next to this the *blue* and *violet* rays; and, lastly, the *white* light; the *red* ray hindering the development of these organisms.

IN the Museum at Cassel, Germany, is a library made from five hundred European trees. The back of each volume is formed of the bark of a tree, the sides of the perfect wood, the top of young wood, and the bottom of old. When opened, the book is found to be a box, containing the flower, seed, fruit and leaves of the tree, either dried or imitated in wax.

The Arts.

ALVAN CLARK AND HIS TELESCOPES.

We have several times alluded to Mr. Clark and his telescopes in the Journal, and we presume our readers will be pleased to learn something of his history.

Just at the end of the Brookline bridge, in Cambridge, stands a modest-looking brick building that most persons would not consider worthy of a second glance, if indeed it attracted their attention, and near this building is another surmounted by a dome. These form the establishment of Alvan Clark, who has a world-wide reputation as a builder of telescopes, and also as an amateur astronomer.

Mr. Clark was originally a miniature painter, and quite a successful one, as many paintings still in his possession prove. Some years ago his attention was accidentally called to the subject of telescope making, from a description given by one of his sons of the small telescope at Amherst College. After hearing this, Mr. Clark remarked that he could make a telescope, and accordingly went to work and made one. His first instrument proved so successful that he was encouraged to persevere. One of his friends remarked to him about this time, "Mr. Clark, if you wish to know how to make telescopes, you will have to go to the place where they are made." But Mr. Clark thought some things might as well be studied out as learned from another, and so persevered, and was soon enabled to retaliate upon his friend by telling him that he had learned how to make telescopes, independent of instructors.

His telescopes are the kind known as *refracting*. In these the principal parts are the field or object glasses, or *objectives*, as they are most frequently called, and the *eye-piece*. The principal use of the objectives is to collect the rays of light coming from the object, and to form an image at the focus of the lens. This image is afterwards magnified by the eye-piece.

On the perfection of this focal image depend to a great extent the power and capabilities of the instrument. It must be colorless, or at least have no fringes on the edges; it must also be sharp and well defined, and have a large amount of light thrown on it. The first two of these conditions may be fulfilled with a glass of a comparatively small diameter, but in order to accomplish the third, the diameter must be increased to as great an extent as possible.

Mr. Clark's first telescopes were distinguished for their freedom from chromatic and spherical aberration, as the first two errors are called, and latterly he has been devoting his time more especially to increasing the size of the glasses.

In order to correct the chromatic aberration, the objective is made of two disks of glass. The first of these, or the convex lens, is made of crown glass. This alone would form an image at the focus, but the image would be fringed with the colors of the spectrum. In order to prevent this, a concavo-convex lens, made of flint glass, is placed directly behind the first glass; this recomposes the white light which the first lens has decomposed, and forms an image at the focus that is almost perfectly colorless. In order to make it perfectly colorless, we should have to use more than two lenses.

There still remains the spherical aberration to be corrected. This is owing to several causes. In the first place, it may be that the glass is a little more dense on one side than on the other; this will serve to distort the image somewhat, and must be corrected by proper grinding. Then a portion of the glass may polarize light while another portion does not; this must also be corrected by grinding.

In order to test the glasses for these errors, they are placed on a carriage and run into a long tunnel which has a small spot of light at the further end. If now the eye is placed at the focus of the lens, a sharp clear image of the spot will be seen, provided the lens is perfect; otherwise it will be distorted and colored. It must also, when examined with a Nicol's prism, still remain free from color. If this is not the case, the glass is removed, repolished, and the test is repeated.

In order to grind the glasses, a coarse emery is first used, until they have been brought very nearly to the perfect form required. Then finer grades of emery are applied, and finally they are polished with rouge. The process takes a long time from the first arrival of the rough glass, until it becomes the finished objective. Almost the whole of the grinding is done by hand, on laps made of cast-iron. These are used at first naked, and afterwards covered with pitch.

Telescopes are generally spoken of as being of so many inches aperture; and until within a very few years a telescope of fifteen inches aperture was regarded as enormous. In 1867, Mr. Clark constructed one of twenty inches aperture, for the observatory at Chicago. This at the time was the largest refracting telescope ever made. Since then one of twenty-four inches aperture has been made in England; and now the Messrs. Clark have orders for two of twenty-five inches aperture; one intended for the government observatory at Washington, the other to go to Virginia.

These telescopes will be about twenty-five feet long when finished, the rule being that a telescope shall be as many feet long as the objective is inches in diameter. Any one who wishes to indulge himself with one of these instruments as a toy, can do so at an expense of about $100,000, and there will most likely be a *further* expense of fifty thousand dollars in providing a place to keep it. These large telescopes are so nicely adjusted that a person can easily move them with a finger, although they weigh several tons. Besides making telescopes, Mr. Clark has made a specialty of spectroscopes. He has constructed some very fine ones; among others that of Prof. Young, to which we have alluded in the Journal. This instrument has been almost completely rebuilt, and some improvements suggested by experience have been added. Mr. Clark has also built a new telescope for Prof. Young, of nine and one third inches aperture. This instrument has a steel tube, made of plates of steel riveted together, as it has been found that steel tubes can be constructed so as to weigh less and yet be stiffer than wooden ones.

Making Light of the Ancient Dead. — It is said that French engineers have "utilized" the mummies in the catacombs of Egypt for making gas, the "candle-power" of which is much increased by the bituminous wrappings.

MEMORANDA IN THE ARTS.

Paper from Oat Husks. — Paper is manu- tured from oat refuse, in Glasgow (Scotland), by immersing the husks in water in a tank, in orde float off mustard and other seeds, with which are frequently more or less mixed, and which, if separated, materially deteriorate the quality of paper. It is of advantage to have the water stirred, as it facilitates the separation of the for seeds, and allows them to float to the surface. oat-husks are then allowed to settle, and the sur scum and floating seeds are drawn off by an o flow pipe at the top of the tank, or skimmed off a rake or other tool, or otherwise removed; which the water is drained from the husks waste-water pipe at the bottom of the tank, beneath a perforated false bottom, or fitted wit strainer, which retains the husks. These may left to steep in the water for from five to ten h after or during the removal of the scum, as steeping, by softening them and helping to lo the silica from the fibre, facilitates the subseq boiling process, by which they are reduced pulp.

A Floating Steam Fire-Engine for V ice. — A light and compact steam fire-engine, fi on an iron screw launch, has just been complete England. The launch is only forty feet long, is specially designed for the canals of Venice draws but 18 inches of water with the eng boiler, and pump, and having on board its and fresh-water supply, as well as its full com ment of firemen. On the trial trip, the sp reached was between 9 and 10 knots per hour. jet of water was projected at a rate of 225 gall per minute to a distance of 156 feet.

Mining Improvements in California. — is claimed that the so-called "giant powder" reduced the cost of tunneling more than twenty- per cent. by permitting smaller drill-holes to used, and by enabling single-handed drills to the work in the place of those operated by two m previously required; the diamond drill has helped much in reducing the cost of this branch mining operations. One instance is mentioned which, driven by steam power, it bored seve twenty-feet holes in three hours, which by the hand method would have kept six men at work three weeks. These and kindred improvements leading to renewed activity in hydraulic mini and bringing into existence projects for supply the mining regions with water which will throw i the shade even the grand achievements which C fornia already shows in this line of engineering.

A Large Steamship. — The Lairds, of Birk head (England), have just launched one of largest ocean steamships ever built. She has b named the *Spain*, and is to form one of the Natio Steamship Company's line between Liverpool New York. Her length is 437 feet, her breadth beam, 43 feet; she is of 4,900 tons burden, and accommodation for 120 first-class and 1,400 steer passengers. The engines of the *Spain* are largest ever constructed on the compound princi and the vessel is expected to have great speed, b under steam and canvas.

Yankee Pins. — There are eight pin factor in the United States, whose annual production 2,000,000 packs, each pack containing 3,360 pi a total of 6,720,000,000 pins. One manufactur agent in Boston sells every six months from 700 1,000 cases of pins, each case containing 672,0 pins. The factory which he represents turns eight tons of pins per week.

Hair-pins are jobbed by the cask. There is one factory in this country that produces the They turn out fifty tons per month. The machi that cuts and bends the wire makes 360 hair-pi per minute, ready for japanning. Yankee pins a

alable in nearly every city of the world, and the production and consumption increase each year about ten per cent.

PRACTICAL RECIPES.

To Make a Superior Sand-Paper. — Take quantity of broken window glass (that which has rather a green appearance on the edge is best); pound it in an iron mortar; then have two or three sieves, of different degrees of fineness, ready for use when wanted. Take any good tough paper (fine cartridge is the best); level the knobs and lumps on both sides with pumice-stone; tack it at each corner on a board, and with good clear glue, diluted with about one third more water than is used generally for wood work, go quickly over the paper, taking care to spread it even with your brush; then having your sieve ready, sift the pounded glass over lightly, yet so as to cover it in every part; let it remain till the glue is set, take it from the board, shake off the superfluous glass into the sieve, and hang it in the shade to dry. In two or three days it will be fit for use.

The paper will be much better than any you can buy — sand being frequently mixed with the glass, and colored to deceive the purchaser.

Recipes for Waterproof Glue. — 1. If for outside work, mix dry powdered white lead in ordinary glue. If for other work, dissolve your glue in the smallest quantity of water possible, then thin with linseed oil.

2. Take of glue twelve parts, and of water or skim milk sufficient to dissolve; then add yellow resin, three parts, and when melted, add turpentine, four parts. Mix well together.

Coloring Metal. — Dr. Puscher gives an account in Dingler's *Journal*, of a process for obtaining decorative colors on metal. Hyposulphite of lead is dissolved in hyposulphite of soda. The clear solution is then heated to 212° Fahr., and the metal dipped into it, when a thin film of lead is deposited, producing a beautiful display of colors upon any metal employed.

To Clean Soft Mahogany, or other Porous Wood. — After scraping and sand-papering in the usual manner, take a sponge and wet the surface to raise the grain; then with a piece of fine pumice-stone, cut the way of the fibres, rub the wood in the direction of the grain, keeping it moist with water. Let the work dry; then, if you wet it again, you will find the grain much smoother, and it will not rise so much. Repeat the process, and you will find the surface perfectly smooth, and the wood much hardened.

Seasoning Wood by Boiling. — Small pieces of non-resinous wood may be perfectly seasoned by boiling four or five hours. Sash frames of Spanish chestnut which has been so boiled have been "wedged up" within six weeks after the tree was felled, and have stood admirably. The boiling takes the sap out of the wood, and most hard woods so treated shrink one tenth in the process.

Tempering Old Files for Chisels. — Heat the file gradually to a cherry red heat, then dip in water about one inch of the chisel end till it comes to a black heat, then rub with a rubber till you see a blue color, then quench it directly. This is the way blacksmiths manage them.

In dressing for photographs, dark brown, dark green, maroon, and plain black goods, without gloss, will make a rich drab color. Silks, of the same colors, will take considerably lighter. Snuff brown, dark leather, dark drab, scarlet, cherry, dark orange, crimson, and slate, will also take a rich drab color. Violet, blue, purple, pink, and magenta will be very light, and should be avoided. The hair should not be very wet or glossy.

Agriculture.

THE USE OF CONCENTRATED FERTILIZERS.

The cause of failure in the use of the concentrated fertilizers is often due to the *manner* in which they are applied. It is difficult for those who have been accustomed to use bulky manures to realize that the full fertilizing potency of a bushel of animal excrement may be held in a large sized table-spoon, and that a handful of one adds to plant structures as decidedly as several shovels full of the other. A full dose of opium as given to patients furnishes quite a dark, bulky powder, or pill; but if we separate the alkaloidal principle upon which its hypnotic power depends, we have only a little delicate white powder which a breath of wind will blow away. The $\frac{1}{8}$ grain powder will affect the human organism as powerfully as ten times the weight of opium. If we were so forgetful of "potencies" as to administer as much, or even one quarter as much, of the white concentrated powder as of the bulky dark one, we should destroy our patient's life, or at least do great injury to his health. So, if in the use of genuine superphosphate, or guano, or ground bones and ashes, we forget their power, and apply too much, or apply them too directly, we endanger the life of our plants.

An experiment made upon corn affords an illustrative case in point. At the time of planting, upon a field divided by a narrow strip of sward land, we directed that on one side a table-spoonful of the mixed bone and ashes should be placed in each hill, and well covered with soil; upon the other, four rows were to be treated similarly, and upon the remainder the hills should receive a double quantity. It is curious to observe the effects. The first field and the four rows are remarkably thrifty. The corn came up well, and has manifested remarkable vigor from the start. On the other hand, the over-dosed corn appeared for a long while as if it had been paralyzed by some wasting disease. It could not bear up under so much of a good thing. More free ammonia was formed at the start than could be appropriated by the tender plants, and many of them perished from over stimulation and heat, produced by the fermentative changes of the active bodies in contact. The corn that survived is at present growing finely, and will no doubt afford a large yield. Now, if this had happened in the course of our regular agricultural labors, and without any understanding of the nature of the fertilizing substance used, it is probable it would have been condemned as a worthless or dangerous article. This has been the case with hundreds of experiments, and is indeed a perfectly natural conclusion to reach. But we must learn to reason, learn to have patience, learn the character of the substances we employ upon our lands. We must be careful how we reach conclusions; we must examine closely to see if they are based upon correct grounds. There are well established principles in agriculture; let us cling to them, and when we get results that are puzzling or paradoxical, we must study causes, and not judge hastily.

The Agricultural Society of Breslau, Germany, offers a prize of $700 in gold for the steam plough apparatus which will work best at trials to be made on farms near that city this summer.

AGRICULTURAL COLLEGE EXPERIMENTS.

Our attention has been drawn particularly to this subject of late by reading the reports of Agricultural Colleges. That of the Pennsylvania Agricultural College is upon the whole an extraordinary document, and deserving of special attention. It shows how empiricism may flourish in high places.

It is evident from the report that considerable work has been done, for which credit should be given to the superintendents of the various farms. As regards these farms, we would remark that it is questionable whether Congress, when the appropriation for agricultural colleges was made, intended the money to be used in buying farms on which the trustees of the said colleges might carry out some pet ideas without cost to themselves. Little of value has been accomplished, and we are free to say that we have never met with a more barren set of figures than those which are scattered so liberally through the report.

The trustees, with the consent of the legislature, have bought three farms, or rather they have bought two, and sold to themselves a third. These farms have been laid out by rule and compass into similar plats, which are to be cultivated in the same manner, using the same manures, and sowing the same seeds.

This all sounds very well on paper, but now comes the gist of the matter. These three farms are in three different parts of the State, with as different soils and climates as could well be found within a radius of two hundred miles from the centre farm, each requiring a different method of treatment, and a careful study of the modes best calculated to lead to instructive or valuable results. Without regard to this, the president of the college directs his subordinates to treat all alike, or bestow upon each the same empirical treatment. He says, "you will apply *commercial manures* and no others to these plats; the manures will be furnished you by the *makers*, who offer to give them for trial." Accordingly, some twenty or thirty different manures, mostly bone phosphates, were begged or bought, and applied to the soils, and the weight of the crops produced was carefully noted. We will quote one result, as showing the value to scientific agriculture of this method of procedure.

Thirty-three commercial fertilizers were applied, at the rate of thirteen and one third dollars' worth to the acre, to as many plats of ground, an adjoining one being left without treatment. One or two of these manures were applied in slightly different ways, making the whole number of experiments forty.

The following are the results: The yield of wheat varied between 6 quarts to the plat, or $7\frac{1}{2}$ bushels to the acre, and 22 quarts to the plat, or $27\frac{1}{2}$ bushels to the acre. The ground on which nothing was applied yielded $13\frac{1}{2}$ quarts, or $16\frac{7}{8}$ bushels to the acre; while the average of the whole number of experiments was $14\frac{1}{4}$ quarts to the plat, or $17\frac{13}{16}$ bushels to the acre. In no single instance is an analysis given of the fertilizer, and nothing is said about its composition. No care was taken to obtain fair commercial specimens, entire reliance being placed upon superphosphate makers and dealers. In other words, in endeavoring to be strictly practical and accurate in the work, they have thrown overboard

all tests except the empirical one of soil application.

A thorough analysis of these manures, such as was published some years ago by the late Dr. Evan Pugh, in *The Country Gentleman*, should have been made, and presented in the report, and this would have given to it some value. If agricultural colleges can do no better than this, they will do but little to benefit the farmer.

INSOLUBLE MATTER.

The following item has had a wide circulation in our exchanges: —

Prof. Johnson don't like the expression "insoluble matter," and remarks that "such exhibitions of professional folly may do for fifty years ago, but in this part of the nineteenth century we recognize no such substance as 'insoluble matter' in our nomenclature. In this same insoluble matter may be hid the very pabulum of vegetable life."

The term "insoluble matter," as applied to soils and fertilizing agents, is an eminently proper one to employ, as it expresses clearly and decidedly the difference between what yields readily to ordinary separating or decomposing agencies, and what does not. In a bag of ordinary "superphosphate," we get a mixture of silica, carbonate of lime, unchanged and changed or dissolved bone, with various kinds of animal matter. In speaking of the component parts of this mixture, we should say that the first two agents are "insoluble" in their nature, and of little benefit to agriculture. In the chemist's laboratory, under the agency of acids, alkalies, heat, etc., they are easily soluble; while in the soil they are practically insoluble, as centuries may elapse before any essential portion of them disappears. There is inexcusable pedantry in the remark attributed to Prof. Johnson, — in fact it is *silly*. But it is a remark which the grinders of "insoluble" rocks, recommended for fertilizing uses, employ to increase their sales, and therefore it is deserving of notice.

PROGRESSION OF PRIMARIES.

The *Journal of Applied Chemistry* has an article supporting at great length Prof. Mapes's doctrine of *progression of primaries*, — which we suppose is not well understood by many of our readers. Briefly, it may be stated thus: minerals that have once passed through a vegetable organization are better adapted for plant food than those derived directly from the rock. He brings up in support of his argument the cases of bone dust and apatite, saying very justly that the first is suitable for the nourishment of plants, while the second is not, evidently considering them as having the same composition. Now in fact they are totally different, the apatite not being a simple phosphate of lime like the bone, but a compound formed from phosphate of lime and fluoride of calcium. If, however, the apatite is treated with strong sulphuric acid, having been previously ground to a powder, it then becomes as suitable plant food as the bone. The simple fact is that phosphate of lime in combination with fluor spar is insoluble in carbonic acid water, while bone dust is soluble to a considerable extent.

A condensed "philosophy of farming": Feed your land before it is hungry; rest it before it is weary; and weed it before it is foul.

WHAT THE HEBREWS KNEW OF FARMING.

In his laws Moses made agriculture the basis of the State. According to this principle he apportioned to every citizen a certain portion of land, marked by fixed boundaries. Land-grabbing speculations were prevented by the law, which required all lands in the commonwealth to revert to the heirs of the original owners on the jubilee year. The occupation of the farmer was held in honor from being thus protected by the fundamental law of the State. None were so rich or noble as to disdain to put their hand to the plow (1 Kings xix. 19; 2 Chron. xxvi. 10.) Various means were resorted to by the Hebrews to increase the fertility of their soil. The stones were gathered and built into walls, water was brought in aqueducts from great distances, and many kinds of manure were used. The hills were terraced to the very tops, and platted with vineyards and gardens. They cultivated wheat, barley, millet, beans, and perhaps rice. (Isa. xxviii. 25.) In agricultural implements the Hebrews were not so far behind the present age as we are prone to think. Isaiah lived 700 years before Christ, yet in his day iron plows were in use, for he prophesied of the time when swords should be turned to plowshares and spears to pruning hooks. This passage shows too that they had instruments for pruning vines and trees. The animals used in plowing were cattle and donkeys. Horses were not in common use among the Hebrews. The original method of harvesting grain was to pull up by the roots, but sickles were used among the Hebrews from the time of Joshua. Harvest among them was a time of rejoicing, cheerful songs being heard in every field. Threshing was effected by flails, the feet of animals, or by drags or rollers. Vineyards and olive groves were extensively and carefully cultivated. Culinary plants and fruit-trees were among the first objects of attention. Palestine was said to flow with milk and honey. Bees were highly esteemed. Their hives were made of clay mixed with straw, but stores of honey were often found in hollow trees and fissures of the rocks. (Psalm lxxxi. 16.) One remarkable provision of the Mosaic law in regard to agriculture was the Sabbatic year. (Lev. xxv. 1–7.) Every seventh year was a year of rest, not so much to the farmer as to the farm. Nothing was sown, and nothing was reaped; the vines were not pruned; there was no gathering of fruit. The object of this regulation seems to have been to preserve the wild beasts, to let the land recover strength, and to teach the people to be provident and look out for the future. But the year was not spent in idleness. The people could hunt, fish, look after their bees and flocks, repair their buildings or furniture, manufacture cloth, or carry on commerce.

THE COW'S INTELLIGENCE.

The London *Milk Journal* remarks: That cows have memory, language, signs, and means of enjoying pleasant associations, combining for aggressive purposes, has been recognized, but scarcely to the extent the subject merits. Travelling in Italy many years ago, we visited some of the large dairy farms in the neighborhood of Ferrara. We happened to stop at a farmhouse one fine autumn afternoon when the cows were about to be milked. A herd of over one hundred was grazing homewards. The women took their positions with stool close to the house, and as the cows approached, names were called out which at first were, we thought, addressed to the milkmaids. Rosa, Florenza, Giulia, Sposa, and many names, which were noted by us at the time, were called out by the overseer, or one of the women, and we were astonished to see cow after cow cease feeding or chewing the cud and make direct, sometimes at a trot, for the woman that usually milked her. The practice we found was not confined to one farm; all the cows on each farm knew their respective names, and took up their position, just as readily as the individual members of some large herds in this country, turning from their fields to take up their places in the sheds.

NOTES FOR THE FARM.

Cooked Food for Cattle. — Experiments made by MM. Raspail and Biot, of the French Academy of Sciences, seem to have resulted in establishing the following points: —

1. That the globules constituting meal, flour, and starch, whether contained in grain or roots, are incapable of affording any nourishment as animal food until they are broken.

2. That no mechanical method of breaking or grinding is more than partially efficient.

3. That the most efficient means of breaking the globules is by heat, by fermentation, or by the chemical agency of acids or alkalies.

4. That the dextrine, which is the kernel, as it were, of each globule, is alone soluble, and therefore alone nutritive.

5. That the shells of the globules, when reduced to fragments by mechanism or heat, are not nutritive.

6. That though the fragments of these shells are not nutritive, they are indispensable to digestion, either from their distending the stomach, or from other causes not understood; it having been found by experiment that concentrated nourishment, such as sugar or essence of beef, cannot long sustain life without some mixture of coarser or less nutritive food.

7. That the economical preparation of all food containing globules or fecula, consists in perfectly breaking the shells and rendering the dextrine contained in them soluble and digestible, while the fragments of the shells are at the same time rendered more bulky, so as the more readily to fill the stomach.

Greasing Wheels. — Many a wheel is ruined by oiling too plentifully. A well made wheel will endure constant wear for ten to twenty years if care is taken to use the right kind and proper amount of oil; but if this matter is not attended to, the wheel will be used up in five or six years, or perhaps sooner. Lard should never be used on a wagon, for it will penetrate the hub, and work its way out around the tenons of the spokes, and spoil the wheel. Castor oil is a good material for use on an iron axle; just oil enough should be applied to a spindle to give it a light coating; this is better than more, for the surplus put on will work out at the ends, and be forced by the shoulders and nut into the hub around the outside of the boxes. To oil an axletree, first wipe the spindle clean with a cloth wet with turpentine, if it won't wipe without it. On a buggy or carriage, wipe and clean off the back and front ends of the hubs, and then apply a very small quantity of castor oil, or some especially prepared lubricator near the shoulders and point.

Gypsum for Leaf Blight. — A correspondent of the *Rural South-Land* recommends the use of gypsum for leaf blight in pear-trees. He says: "In July last I sprinkled it freely on the trees affected, early in the morning, when the few leaves remaining and twigs were wet with dew, and succeeded in checking the disease in some, and completely renovating the entire foliage in a very short time in all. The kinds most subject to leaf blight with me are Glout Morceau, Seckel, Flemish Beauty, Swan's Orange, and one or two others."

Mr. Greeley says that people who have owned grazing lands and stock in Texas have grown rich of late years without effort, and almost without thought.

Boston Journal of Chemistry.

JAS. R. NICHOLS, M. D., *Editor.*
WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, AUGUST 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to editorial affairs ould be addressed to the Editor, 150 Congress reet, Boston.

ANALYSIS OF BOSTON STREET DUST.

WITH the view of ascertaining the composition f he ordinary dust or dirt found in the streets ur city, we have collected specimens from us points and subjected them to chemical ysis.

he following table indicates the nature of the mens and the localities from which they taken: —

	Organic matter.	Inorganic matter.	Insoluble in nitro-muriatic acid.	Sesqui-oxide of iron.
No. 1,	30.60	69.40	53.02	7.15
No. 2,	15.34	84.66	76.56	6.85
No. 3,	26.43	73.57	61.33	7.83
No. 4,	13.39	86.61	76.70	7.76
No. 5,	14.83	85.17	73.45	7.64
No. 6,	22.13	77.87	73.45	
No. 7,	18.51	81.49		
Averages,	20.19	79.82	69.08	7.44

No. 1. State Street, in front of the Post Office.
No. 2. West Boston Bridge.
No. 3. In front of 150 Congress Street.
No. 4. Corner of Congress and Purchase Streets.
No. 5. Broad and Pearl Streets.
No. 6. Beverly and Causeway Streets.
No. 7. Court Street (Nicholson pavement).

T specimens were carefully dried at 100° C. d ve off all moisture, and weighed portions hen taken and ignited until they ceased to veight. The residue was weighed and with aqua regia, and the portion insolu- acid was again weighed. The iron was tated and weighed as sesquioxide.

T organic or vegetable and animal matter omposed of various substances, such as animal excrement, hair, filaments of cot- ool, and leather, etc., the hair and excre- oming principally from horses, the cotton, wool, and leather from the clothing and boots and shoes of pedestrians. The inorganic parts contained, beside the iron and sand, considerable quantities of lime, chloride of sodium, traces of phosphoric acid and other substances. The iron came from the shoes of horses, the tires of wheels, and the nails in the heels of boots and shoes.

Some curious and instructive facts are learned from this investigation, the most prominent of which are, first, the low value of street sweepings as manure. Estimating pure horse excrement at eight dollars the cord, or two dollars the ton, four tons to the cord, the value of street sweepings, counting all the volatile matter as equivalent to horse manure, would not go above *forty cents a ton,* when perfectly dry. The dirt of streets, as collected in most localities, would probably go considerably below this in manurial value. We learn upon inquiry, both here and in New York, that farmers and gardeners have found that street sweepings exert but little fertilizing influence upon crops. There is a vast difference in value between the sewerage or liquid waste of a great city, and the dust above ground.

Second. It is curious to observe the uniformity with which the metal iron prevails in the different streets. It falls off a little in specimen No 2, taken from West Boston Bridge. The abrading, disintegrating influence of paving stones upon iron is very clearly shown in the investigation. The dust taken from the Nicholson pavement in Court Street contained more rocky or inorganic material than that from some of the paved streets of the city. Doubtless this had been removed from contiguous streets by wind, and in the form of mud, upon wheels and horses' hoofs.

The bearings of the investigations upon public hygiene are not unimportant. We learn regarding the nature of the impalpable powder which is hurled in our faces and into our mouths on windy days. The filthy excrementitious matter, associated with filaments of animal and vegetable waste, and minerals, and mineral salts, constitute a compound neither healthy nor pleasant to inhale into the lungs or take into the stomach. Contact with this street dust is, however, to a great degree unavoidable in a city, and, do what we may, we must continue to swallow it so long as business or pleasure inclines us to a city life.

POROUS CONE FILTERS.

IN Bunsen's paper on filtration by means of the water-pump, he mentions the use of cylinders of glass closed at their lower ends by plates of porous earthen-ware. Mr. C. E. Munroe, late of the Lawrence Scientific School, has with the aid of Messrs. A. W. and H. C. Robertson of Chelsea, Mass., improved upon this suggestion. At his instance they have experimented upon and at last succeeded in making cones of porous earthenware that answer every purpose of the paper filter. These cones are not sufficiently porous to admit of being used without the Bunsen pump, but with it they answer admirably. After being boiled with strong hydrochloric acid, washed with water, and dried, their weight remains perfectly constant, even after repeated filtrations and dryings. This property will be appreciated by those who have used paper filters for such purposes as the estimation of arsenic and antimony, and such other substances as require the use of filters dried at 100° C.

In order to use them they are placed inside of an ordinary glass funnel, a narrow section of seamless rubber tube having been first stretched over the mouth of the funnel; this forms a perfectly air-tight joint. The funnel is then connected with the Bunsen pump in the ordinary manner.

Mr. Munroe, in his very interesting paper on this subject in the *American Journal of Science and Arts,* for May, gives a number of analyses made by the use of these cones, which are remarkable for their accuracy. He also suggests their use in manufacturing operations, for draining crystals and filtering corrosive liquids.

THE BIG TREES OF CALIFORNIA.

REV. DR. SEELEY of Haverhill, Mass., who has recently visited California, sends us the following observations regarding the big trees in Calaveras County: —

I venture to send you a few words concerning the giant "Redwoods" of California. These trees are unlike the common red cedars of the Eastern States in the texture of the bark, which is thick and spongy; in the color of the wood, which is a brownish red throughout; in the formation of the leaves, which, though round and scaly, are much larger in proportion, and do not grow in triplets; and in the character of the fruit or seeds; for while the *Juniperus Virginiana* is bacciferous, the Redwood is coniferous.

The name "Arbor Vitæ" is sometimes given to the "Redwood," and I noticed a sign attached to one of the monsters in Calaveras County, containing the words "Arbor Vitæ Queen." It is a misnomer, however. For while the Sequoia is like the *Cupressus thyoides occidentalis* in being coniferous, and in the *color* of its foliage, the latter is dissimilar in other respects, — being round instead of flat, and not so ramose, having none of that peculiar appearance which, I suppose, gives to the white cedar the name of *Arbor vitæ.*

The "Redwood" also differs from the Cedar of Lebanon in the formation of both leaves and branches, and in the general shape and growth of the tree. Those specimens which I have seen of the latter throw out numerous, strong, horizontal branches, which from quite low down on the trunk to the top of the tree, form a succession of broad, flat, table-like surfaces or terraces. The Redwoods, on the contrary, rise from the ground somewhat like the cypress of the Southern States, pyramidally, and tower frequently more than a hundred feet without a limb; while the tops are smaller and more compact than those of most other trees in proportion to their size.

While the Redwoods thus form a species by themselves, which has been named the "*Sequoia gigantea sempervirens,*" they are much more widely removed from all others by their enormous proportions in height and in diameter of trunk. Several groves of the species have been discovered in California, as at Mariposa, Fresno, "the Calaveras grove," another six or eight miles distant, and still others. Indeed the wood is used by the Californians in house-building, very much as the white pine is with us at the East. Of these groves, that at Mariposa contains the greatest number of trees, and that mentioned above as near the Calaveras grove, presents specimens, the trunks of which are larger in diameter than any others yet discovered; but for both height and size those of the latter stand preëminent.

This grove is about seventy-five miles east, or

northeast from Stockton, in a valley on the western slope of the Sierra Nevadas, and so situated that while it receives the full benefit of those climatic influences which are most favorable to vegetable growth, it is greatly sheltered from strong winds. When I was there, in the latter part of April last, the temperature and state of the atmosphere were those of a well regulated hot-house.

This grove contains nearly one hundred of the large Sequoias. Among them are ten whose trunks are each equal to thirty feet in diameter (near the ground), and seventy that are between fifteen and thirty feet in diameter. Many are over three hundred feet in height. Several have fallen. Of these, "*The Miner's Cabin*" * — blown down in 1860 — was three hundred and nineteen feet in length, and twenty-one and a half feet in diameter: "*Hercules*" — blown down in 1862 — was three hundred and twenty-five feet long, and at the upturned base, ninety-seven feet in circumference: while "*The Father of the Forest*" — also down — is estimated by Hittel to have been *forty feet* in diameter, and *four hundred and fifty* feet in height, or twice as high as Bunker Hill Monument.

I took a fancy to test the size of this tree at one hundred and fifty-four feet distant from its base; and by my rude measurement it proved to be more than eleven and a half feet without the bark.

One of these monsters was felled in 1853, five men being engaged twenty-five days, and achieving the feat by the use of large pump augers. The diameter of the stump measured nearly twenty-four feet across without the *bark*, which would have added two and a half or three feet to the measurement. The end of a stick cut from this tree contains twenty-four "rings" to the inch. If the stick had been taken from the section next the stump, this would give from the centre to the outer edge, next the bark (*i. e.* one half the total diameter) 288 $\times$ 12 = 3,456 "rings" in the tree; and according to the ordinary method of reckoning, this tree would be three thousand, four hundred and fifty-six years old.

But since the stick may have been taken from an upper section of the trunk, where the dimensions were less and the distances between the rings were less, this method of calculating the age of the tree is not reliable. But even if the actual count of rings on the stump were three thousand four hundred and fifty six, *it is doubtful whether the age of the tree is greater than half that number of years.*

My reasons for this doubt are the following: These trees grow in a region where other species of trees are very thrifty, — the Sugar Pines and Yellow Pines in the Calaveras grove being, in many instances, two hundred and fifty feet high, and from eight to ten feet in diameter. The Redwoods themselves evidently are fast growers; but unlike thrifty trees with us, these giants exhibit a closeness of the rings which does not betoken thrift. I suspect, therefore, that each tree makes two growths in a year.

This suspicion may not appear entirely absurd when we reflect on the peculiarity of the seasons in California. The spring rains fall in March and April, after which there is no more moisture until October, when the autumnal rains commence; and by the early part of December (if I am rightly informed), the winter, with frosts and deep snows, takes possession of the mountain districts, where the colossal Sequoias flourish, not to withdraw its reign until April. Consequently these trees have that short season which intervenes between the October rains and the commencement of winter for an *autumnal* growth, and another season between the disappearance of winter and the time when they feel the summer drought for a *spring* growth. For while they may find abundant moisture long after plains, hills, and mountain sides equally exhibit their brown sandy hue, and the lesser forms of vegetation are completely parched, yet since the roots of these cedars seem to run rather horizontally than deep, they also must finally feel the drought, and cease to make any growth till autumn.

The correctness or incorrectness of this supposition can be demonstrated by cutting down a tree in one of the "groves," the exact age of which is known, and comparing the age with the number of its rings. Until this shall be done, I must regard the supposition as sufficiently plausible to warrant us in reckoning the age of the Sequoias at only half that which has commonly been attributed to individuals of the species.

* Many of the large trees bear the names of distinguished individuals, *e. g.*, of George Washington, Andrew Jackson, Daniel Webster, Abraham Lincoln, Generals Grant, Sherman, McPherson, and Sheridan; of the poets, Longfellow and Bryant; of the savants, Humboldt, John Lindly, Professor Asa Gray, and Dr. John Torrey.

ANALYSIS OF A CLAM SHELL.

From whence does the clam obtain the lime needed to form its shell? This is an interesting question, and one we have often asked ourself when observing the bivalves in salt and fresh water basins. As considerable lime is found in sea-water the question is not so puzzling in its connection with the clams, oysters, etc., of the ocean, as with those of our fresh water lakes.

In order to obtain light upon the matter we took from Lake Kenosa, upon which our farm borders, a *Unio* or blue shelled muscle, and separating the shell submitted it to chemical analysis. The amount of lime contained in it, in the form of carbonate, was 14.75 grams, with a trace of phosphate. We also subjected the water of the lake to analysis, and found that each 1,000 grams of the water held 0.0268 grams of lime, principally in the form of carbonate. These results show, if the clam obtains its lime wholly from the water which passes through the organs of assimilation, that 532 litres would be required, or in other words more than *four barrels* of the water of the lake were needed to supply the lime which the clam derived from some source. We have thus far investigated the matter strictly from the chemist's stand-point, and having but little knowledge of the nature of the food required by the clam, or its habits, etc., we would ask some of our naturalists to enlighten us upon these points.

THE LAWRENCE SCIENTIFIC SCHOOL.

At the close of the term ending June 25, 1871, the Chemical Department of the Lawrence Scientific School ceased to exist.

This was the oldest school of Chemistry in this country, and its many graduates will hear with sorrow the news of its discontinuance. The number of students has never been very large, not averaging more than ten or twelve for the last five years; the aim of the school being rather to give thorough instruction to a few students, than general instruction to a large number. During the twenty-three years of its existence it has been under the charge of but two professors, Prof. Horsford and Dr. Gibbs, although Mr. C. W. Eliot was temporarily in charge of it between the administrations of the two gentlemen above named.

Dr. Gibbs still continues at Cambridge as Rumford Professor, and has been assigned to the department of Physics. He will lecture during the coming year on the subjects of Light and Heat.

ANOTHER FATAL CASE OF ZINC POISONING.

The wife of Col. Horton, of Attleboro, Mass., recently died from the effects of the salts of zinc, contained in water used for culinary purposes. The case is described by the attending physician, J. Bronson, M. D., of Attleboro, who is a gentleman of high standing in the profession, a member of and, we believe, one of the Councillors of the Massachusetts Medical Society. Dr. B. says: "That Mrs. Horton was poisoned by water drawn through galvanized iron pipes is, I believe, fully demonstrated by physical evidence. The salts of zinc were doubtless eliminated before death, but they primarily induced the disease of which she died." This adds one more to the list of those who have fallen victims to the insidious influence of a metallic poison introduced into the system through the medium of bad water pipes.

A heavy responsibility rests upon those who are advocating the continued use of the galvanized pipes for water conduction. We have discharged our duty in calling attention to the great evil, and warning our readers against it.

LIEBIG ON GERMANY AND FRANCE.

At a recent meeting of the Royal Bavarian Academy of Sciences, Baron Liebig spoke thus of the future relations between Germany and France: "The Academy seizes this moment to declare openly that there exists no national hatred between the German and Latin races. The peculiar character of the Germans, their knowledge of languages, their acquaintance with foreign people, the past and present state of their civilization, all tend to make them just towards other peoples, even at the risk of often becoming unjust towards their own, and thus it is that we recognize how much we owe to the great philosophers, mathematicians, and naturalists of France, who have been in so many departments our masters and our models. I went forty-eight years ago to Paris to study chemistry; a fortuitous circumstance drew upon me the attention of Alexander Von Humboldt, and a single word of recommendation from him caused M. Gay Lussac, one of the greatest chemists and physicists of his time, to make to me, a young man of twenty, the proposal to continue and finish with his coöperation an analysis which I had commenced. He introduced me as a pupil into his laboratory; my career was fixed after this. Never shall I forget the kindness with which Arago and Thenard received the German student, and how many compatriots, physicians, and others, could I not name, who, like myself, gratefully remember the efficacious assistance accorded to them by French men of science in finishing their studies. An ardent sympathy for all that is noble and grand, as well as a disinterested hospitality, form some of the most noble traits of the French character."

EDITORIAL NOTES.

Editorial Excursion. — We were prevented by a press of duties from joining the excursion of the editors and publishers of Massachusetts, New Hampshire, Maine, etc., in July. It would have been a great pleasure to have met our editorial friends, with whom we passed some pleasant hours at Lakeside last autumn. The excursion was a complete success, and full of enjoyment.

The Hay Crop. — The complaint comes from all sections of New England and from New York that the hay crop this season is a partial failure. It will not probably prove to be two thirds as large as usual, which is a serious matter to farmers. Our hay crop at Lakeside is larger than ever before from the same area of land. Our reclaimed meadows gave immense crops, fully three tons of timothy to the acre; and our uplands, notwithstanding the drought, supplied heavy swarths to the mower. It is certain, high cultivation renders lands, in unfavorable seasons even, productive. The influences of drought, cold, wet, etc., upon properly tilled fields is much less than upon those impoverished or n-

ected. The farmer cannot afford to imperfectly ultivate his tillage lands, as any disturbing weather nfluences cut short his moderate or scanty crops, nd destroy his courage and his hopes.

Some Ugly Bugs. — A friend in Illinois has ent us some living specimens of the Colorado Potato Bug, which is now ravaging the potato fields of our Western cultivators. We have placed the insects n a glass bottle, and guard them against escape ith as much vigilance as the warden of a penitenary guards his prisoners. It is hoped that no one's uriosity will lead to the introduction of the detestble bugs into the Eastern States, for they are comg upon their own account fully fast enough. The otato bug has a wonderful tenacity of life, and but w of the ordinary insect poisons affect him. He ill burrow through a heap of carbolate of lime as woodchuck does through a clover patch, and a satrated solution of the agent appears to afford him agreeable bath. Arsenic and arsenical compounds heck him when fairly brought in contact with em, and so do the salts of mercury. It should be id that carbolate of lime is evidently very offenve to the insects, but it does not destroy them. Vhen placed on glass inclosed in a ring of the rbolate, they are greatly disturbed, and will not aproach it at any point. It may be that it will drive em from a field, and some experiments with it are orth trying. The arseniate of copper, or what is nown in commerce as Paris Green, has been found effective antidote to the bug, and inquiries are nstantly made of us regarding the safety of the ent. It is indeed a vile poison, and if any subtute can be discovered it should be discarded. great has been the demand for it of late that ere is great activity manifested in its manufacture. ut it is very destructive to the health and lives en of workmen, and it is difficult to find men who ll aid in its production. Arsenic and copper are o unpleasant minerals to be associated, and it is estionable whether it should be used as a paint. regards potato fields we incline to think that no ury can result to the crop where it is used. here is danger in handling it, but if our own fields re being devoured, we should use it if we could d no substitute.

The destruction of the potato crop is an evil of pendous magnitude, and nothing must be left unne to avert it. It cannot be a great while before depredator will reach our borders, as from last ounts he was advancing East by forced marches. insects destructive to vegetation increase in num and in new varieties as rapidly during the next rter of a century as they have during the last, shall only be able to raise a few fruits, grains, l roots, and these will have to be cultivated under ss.

Bradford Academy. — We have never atded a school exhibition of so pleasing and satisory a character as that at Bradford in July last. is is a young ladies' school, and is made up of ils from all parts of the country, the number at sent being about one hundred and twenty. The rcises were of a high order, and everything was racterized by good sense, and a refined and al tone, which gave great pleasure to the parents he young ladies and the numerous friends of the itution. In saying that we regard Bradford demy as a model school, we repeat what we have re said in the Journal. The elegant, spacious, venient building standing as it does in one of most charming localities in New England, gives dvantages hardly possessed by any other. The rd of Trustees, embracing such men as Dr. us Anderson, E. S. Tobey, Ezra Farnsworth, ner Kingman, S. D. Warren and others of this , Dr. Cogswell of Bradford, Dr. Durfee of Fall er, etc., is a guarantee that its interests will be cared for, and that parents can safely place their daughters in such charge. Miss Abby Johnson, the principal is now in Europe, but will reach home in season to take charge of the school in September.

The Sandwich Islands. — One of our subscribers at Honolulu writes as follows, under date of June 8, 1871. "Please find enclosed two dollars, for which I wish to renew my subscription for *two years in advance*. At this great distance from the United States and from opportunities for literary and scientific improvement, there is no periodical which better meets our needs, or is more prized than the Boston Journal of Chemistry." Similar letters come to us by every mail from all parts of our own country and from foreign lands, and we have to thank our friends for their kind partiality and words of commendation.

Be Just. — We are pleased to have our articles copied by exchange journals, when due credit is given, but we dislike the dishonesty of some who appropriate our articles as their own, or who forget to give credit when copying them. We can hardly take up a paper without noticing instances of this character. An article of ours upon "Dangerous Burning Fluids" is now going the rounds of the press credited to the *Indiana Journal of Medicine*. Every word of the article is taken from the Journal, and we learn that it was copied into the *Indiana Journal* and no credit given. The last number of the *Druggists' Circular* copies it, giving credit to the *Indiana Journal of Medicine*. We are sorry to have to call attention to this matter.

Scientific Expedition. — Professor Agassiz, who will be accompanied by Ex-President Hill of Harvard University and Mr. Pourtalis of the Coast Survey, proposes to start in the autumn on a trip around Cape Horn. They will sail in a vessel that is being built for the service of the Coast Survey on the Pacific Coast. Mr. Nathaniel Thayer, with his accustomed liberality, has offered to defray the scientific expenses of the party. They expect to make dredgings at various points, and to make a full examination of the Straits of Magellan, paying particular attention to marks of glacial action.

ATOMS.

A French inventor proposes a composition of glue, honey, water, and glycerine as a vehicle for the colors used in printing-ink, instead of the ordinary oil or varnish. — It is stated that the only establishment for the manufacture of plate glass in this country is at Lenox, Mass. — Last year we imported more than nineteen million pounds of jute, at a cost of three millions of dollars, though the plant could readily be raised at the South, where it is used extensively for bale-cloth. — Oiling the points of nails will enable one to drive them into hard wood more easily. — Bees are now sent by mail, confined in a square block of wood, with auger holes bored in it and covered with wire gauze. — French gold leaf does not exceed the 480,000th of an inch in thickness. — Dr. Luther, in the *Medical Press and Circular*, states that he reduced strangulated hernia by causing to be applied, over the part, extract of belladonna rubbed up with glycerine. — The leather interest in this country amounts to more than two hundred millions of dollars annually, exceeding every other industrial pursuit except agriculture. — An inch of rain falling upon an acre of ground supplies it with about a hundred tons of water. — The Commissioner of Internal Revenue has decided that the dust produced in the tobacco manufactories, which cannot be made into snuff or put into any other shape absorbable by the human system, may be disposed of to farmers for fertilizing purposes. — In Montana farmers have been unable to plant all their grain on account of the scarcity of help. — It has been calculated that the fences of the United States have cost an amount equal to the present national debt, and that the annual repairs of the same absorb some two hundred millions of dollars. — Speaking of fences, the Chicago and Alton Railroad has about one hundred and fifty miles of Osage orange hedge along its line, and is steadily adding more. — Professor Boettger of Germany tests the genuineness of silver plating on metals in the following manner: the metallic surface is carefully cleaned, and a drop of cold saturated solution of bichromate of potash in nitric acid is placed upon it, and immediately washed off with cold water; if the surface is silver, a blood-red spot of chromate of silver is formed, whereas on German silver or Britannia metal the stain is brown or black. — Mr. Whitehead, the inventor of the "fish torpedo," has sold his device to the English Government for seventy-five thousand dollars. — Peter the Great was born on the 9th of June, 1672, and an industrial exhibition is to be held next year at Moscow, in honor of the bicentennial anniversary of the event; and among the articles exhibited will be the famous boat made by the Emperor, which is still in a good state of preservation at St. Petersburg. — Europe has 450,000 miles of telegraph wire, and 13,000 stations; America, 180,000 miles of wire, and 6,000 stations; India, 14,000 miles, and 200 stations; Australia, 10,000 miles, and 270 stations; and the extension throughout the world is at the rate of 100,000 miles of wire per annum; to say nothing of 30,000 miles of submarine cable now in successful operation. — The Pennsylvania State Medical Society has rescinded its resolution denying recognition of female physicians, or of medical men who consult with women or teach female students. — Photography is used in the United States Pension Bureau to detect those who attempt to get a double share of pension money. — In England, the extent of land covered with trees has increased forty thousand acres in the last thirty-five years, and tree planting is encouraged among landholders by liberal premiums. — In Italy, seaside hospitals for poor scrofulous children have been established by charitable persons; and of 290 children treated last year at these establishments, 102 were cured, and 79 materially benefitted. — After more than a year of careful investigation, a Government Commission in British India has decided on a gauge of three feet and three inches for the railways there; which extends the narrow-gauge system to nearly ten thousand miles of road. — Chignons and kindred vanities of the hairdresser's art have recently been made of spun glass, which has the advantage of being cleaner than any of the materials hitherto used. — A party from the Massachusetts Institute of Technology, headed by President Runkle, and consisting of Professors Ordway, Rockwell, Richards, and Hyatt, with fourteen students of mining and metallurgy, has started for Colorado and the adjacent regions, where they will be occupied in scientific research and practical work until about the first of October. — Massachusetts has one mile of railway for every five square miles of her area. — Dr. W. H. Searles recommends poultices of tea-leaves, moistened with hot water, as preferable to all other remedies in the first stage of burns and scalds.

ANSWERS TO CORRESPONDENTS.

Druggist, Portland, Me. Cundurango is a plant or tree growing in the province of Loja, Ecuador, specimens of which were sent to Washington for analysis and trial as a medicinal agent. A great noise has been made regarding it by correspondents of newspapers, which we suppose is a new way of advertising a nostrum which it is in contemplation "to put on the track" as a sovereign cure-all for *cancer* and other malignant affections. Dr. Antisell, of Washington, has subjected the plant to chemical examination, and finds it to present no unusual characteristics. He is inclined to class it among the "aromatic bitters," and states that what little medicinal virtue it has resides in the bark. Mr. Speaker Colfax is giving the thing a notoriety by alleging that it has "cured his mother-in-law of

cancer." This sounds very absurd to intelligent physicians, who know that cancer is not a local trouble, but a disease affecting the system generally, and of a most malignant nature. We advise our readers not to invest very largely in *cundurango*, or any other nostrum claiming to have extraordinary virtues.

S. T. V., HARTFORD, CT. If your zinc-covered iron pipe has been in the well for three years, as you state, it may as well remain, as undoubtedly the zinc has entirely disappeared, and you have iron surfaces in contact with the water. The zinc coating is usually removed from iron pipes, where water is passing through, in from four to six months, and it is then like ordinary iron pipe, and ceases to be dangerous. In some cases, we have known patches of the zinc to remain upon the iron for two or three years, but such instances are rare.

L. M., UTICA, N. Y. A razor is kept in good condition by stropping it after it is used. We have one which has been in constant use for fifteen years, and it has never been in contact with a hone or stone of any kind; it is always passed over the strop before it is put away.

J. M. W., WATERBURY, CT. You can hardly afford to use potash at ten cents a pound for fertilizing purposes. Ashes, unleached, are cheaper at forty cents a bushel.

W. H. R., OLANTHE, KANSAS. Water in freezing rejects most impurities. The ice collected from a mud puddle, as you have doubtless observed, is free from dirt or filth. In collecting ice for domestic uses, it is preferable to obtain it from clear ponds or springs, if they are accessible.

H. C., PROVIDENCE, R. I. We have found ashes, bone dust, and Peruvian guano to be excellent fertilizers for strawberries. Good, well seasoned barn-yard manure is used by many of the successful cultivators of the berry in the vicinity of Boston.

M. N. O., BOSTON. We quite agree with you, that unless some varieties of strawberries other than the Wilson's Albany are cultivated for market purposes, the sales of the berry will be small in the future, for it is quite too acid and flavorless for most consumers. It is a good berry to keep and to transport, and it is productive, but for table uses it is almost unendurable.

P. N. S., PROVIDENCE, R. I. It is doubtful if you can destroy the canker worm by placing saltpetre around your trees. It is an expensive salt, and it has not been proved that it will destroy the grub or worm when brought in contact with them.

J. N. S., ST. ALBANS, VT. If you sprinkle carbolate of lime in the rear of your horse stalls, it will serve to keep away flies, and render your stable sweet, and healthy for the horses.

C. P., BOSTON, MASS. The water cans made for holding ice water, and used in hotels, public rooms, and sometimes in private dwellings, are filthy and unsafe vessels, and should be abandoned. We refer to those made of zinc, painted on the outside, with a sheet zinc lining inside. They have a metallic faucet, and as found in the market are labelled in paint "Ice-water." There is often a metallic taste conferred upon the water by these cans, which is distinctly observable. No more dangerous or uncleanly vessel for holding ice-water has ever been devised, and we advise thirsty ones to give them a wide berth when in pursuit of cooling drinks.

Medicine.

ABORTIVE TREATMENT OF FELONS.

ONE of the most painful afflictions from which any one can suffer is a felon or whitlow; and as I have had great success in the treatment of these distressing forms of disease, I will, with your permission, give your readers an idea of the method adopted.

It is well known by physicians that pressure causes absorption, and in view of this fact, ten years ago I adopted the plan of applying several coatings of collodion over the finger or place where the pain is felt on its first appearance. On drying, the collodion contracts with an even pressure, and if kept on for twenty-four hours the symptoms will usually entirely disappear.

Of late I have been in the habit of soaking the affected part in quite a strong solution of carbolic acid for a few minutes before applying the collodion.

The pain for some hours will be quite severe, but an anodyne will afford relief. J. H. S.

AUGUSTA, ME.

REMARKS. — We have to thank our correspondent for suggesting a remedy for a distressing affection. The sufferings experienced from whitlow are very great, and if the simple plan of treatment described above proves effective he deserves the thanks not only of the medical profession but of every one. Our correspondent is a medical gentleman of high respectability.

TYNDALL ON DUST AND SMOKE.

WE find in our English exchanges, reports of a lecture delivered by Prof. Tyndall, at the Royal Institution, on the 9th of June. The theme was "Dust and Smoke," and the discourse may be viewed as supplementary to the famous one on "Dust and Disease," delivered January 21, 1870. It is quite as interesting as its predecessor, and will probably attract quite as much attention.

Having shown some introductory experiments illustrating the polarization of light by floating dust, and by smoke of various degrees of density, the speaker proceeded to show the practical bearing of these investigations. After admitting that in themselves the curious phenomena he had been showing are "worth nothing," that "they will not enable us to add to our stock of food or drink or clothes or jewelry," he went on as follows: —

But though thus shorn of all usefulness in themselves, they may, by leading the mind into places which it would not otherwise have entered, become the antecedents of practical consequences. In looking, for example, at this illuminated dust, we may ask ourselves what it is. How does it act, not upon a beam of light, but upon our own lungs and stomachs? The question at once assumes a practical character. We find on examination that this dust is organic matter — in part living, in part dead. There are among it particles of ground straw, torn rags, smoke, the pollen of flowers, the spores of fungi, and the germs of other things. But what have they to do with the animal economy? Let me give you an illustration to which my attention has been lately drawn by Mr. George Henry Lewes, who writes to me thus: —

"I wish to direct your attention to the experiments of Von Recklingshausen, should you happen not to know them. They are striking confirmations of what you say of dust and disease. Last spring, when I was at his laboratory in Würzburg, I examined with him blood that had been three weeks, a month, and five weeks, out of the body, preserved in little porcelain cups under glass shades. This blood was living and growing. Not only were the Amœba-like movements of the white corpuscles present, but there were abundant evidences of the growth and development of the corpuscles. I also saw a frog's heart still pulsating which had been removed from the body (I forget how many days, but certainly more than a week). There were other examples of the same persistent vitality or absence of putrefaction. Von Recklingshausen did not attribute this to the absence of germs — germs were not mentioned by him; but when I asked him how he represented the thing to himself, he said the whole mystery of his operation consisted in keeping the blood *free from dirt.* The instruments employed were raised to a red heat just before use, the thread was silver thread and was similarly treated, and the porcelain cups, though not kept free from air, were kept free from currents. He said he often had failures, and these he attributed to particles of dust having escaped his precautions."

Prof. Lister, who has founded upon the removal or destruction of this "dirt" great and numerous improvements in surgery, tells us of the effect of its introduction into the blood of wounds. He informs us what would happen with the extracted blood should the dust get at it. The blood would putrefy and become fetid, and when you examine more closely what putrefaction means, you find the putrefying substance swarming with organic life, the germs of which have been derived from the air.

Another note which I received a day or two ago has a bearing particularly significant at the present time upon this question of dust and dirt, and the wisdom of avoiding them. The note is from Mr. Ellis, of Sloane Street, to whom I owe a debt of gratitude for advice given to me when sorely wounded in the Alps. "I do not know," writes Mr. Ellis, "whether you happened to see the letters, of which I enclose you a reprint, when they appeared in the *Times.* But I want to tell you this in reference to my method of vaccination here described, because it has, as I think, a relation to the subject of the intake of organic particles from without into the body. Vaccination in the common way is done by scraping off the epidermis, and thrusting into the punctures made by the lancet the vaccine virus. By the method I use (and have used for more than twenty years) the epidermis is lifted by the effusion of serum from below, a result of the irritant cantharidine applied to the skin. The little bleb thus formed is pricked, a drop of fluid let out, and then a fine vaccine point is put into this spot, and after a minute of delay it is withdrawn. The epidermis falls back on the skin and quite excludes the air, and not the air only, but what the air contains.

"Now mark the result — out of hundreds of cases of re-vaccination which I have performed, I have never had a single case of blood-poisoning or of abscess. By the ordinary way the occurrence of secondary abscess is by no means uncommon, and that of pyæmia is occasionally observed. I attribute the comparative safety of my method entirely, first, to the exclusion of the air and what it contains; and secondly, to the greater size of the apertures for the inlet of mischief made by the lancet."

I bring these facts forward that they may be sifted and challenged if they be not correct. If they are correct it is needless to dwell upon their importance, nor is it necessary to say that if Mr. Ellis had resigned himself wholly to the guidance of the germ theory he could not have acted more in accordance with the requirements of that theory than he has actually done. It is what the air contains that does the mischief in vaccination. Mr. Ellis's results fall in with the general theory of putrefaction propounded by Schwann, and developed in this country with such striking success by Prof. Lister. They point, if true, to a cause distinct from bad lymph for the failures and occasional mischief incidental to vaccination; and if followed up they may be the means of leaving the irrational opposition to vaccination no ground to stand upon, by removing even the isolated cases of injury on which the opponents of the practice rely.

It will be recollected that Tyndall was severely criticized in some quarters for the introduction of the germ theory of disease into his former lecture. He now declares that these criticisms have not led him to regret having spoken as he did; and he thus concisely and forcibly states "the grounds on which the supporters of that theory rely:" —

From their respective viruses you may plant typhoid fever, scarlatina, or small-pox. What is the crop that arises from this husbandry? As surely as a thistle rises from a thistle seed, as surely as the fig comes from the fig, the grape from the grape, the thorn from the thorn, so surely does the typhoid virus increase and multiply into typhoid fever, the scarlatina virus into scarlatina, the small-pox virus into small-pox. What is the conclusion that suggests itself here? It is this: That the thing which we vaguely call a virus is to all intents and purposes a *seed:* that in the whole range of chemical science you cannot point to an action which illustrates this perfect parallelism with the phenomena of life — this demonstrated power

of self-multiplication and reproduction. There is, herefore, no hypothesis to account for the phenomena but that which refers them to parasitic life.

In this connection the lecturer quotes a letter addressed to him by Dr. Wm. Budd, well known n England for his activity in the cause of sanitary reform. After remarking that he is fully atisfied that "the specific cause of contagious evers must be living organisms," Dr. Budd dds: —

"It is impossible, in fact, to make any statement earing upon the essence or distinctive characters f these fevers, without using terms which are of ll others *the most distinctive of life.* Take up the ritings of the most violent opponent of the germ heory, and, ten to one, you will find them full of ich terms as 'propagation,' 'self-propagation,' 'reroduction,' 'self-multiplication,' and so on. Try s he may — if he has anything to say of those iseases which is characteristic of them — he canot evade the use of these terms, or the exact quivalents to them. While perfectly applicable living things, these terms express qualities which e not only inapplicable to common chemical gents, but as far as I can see actually inconceivble of them."

The remainder of the lecture is devoted to the ibject of *respirators,* which had been recomended in the former lecture as a safeguard gainst miasmata and infectious diseases. There n be little doubt of their value for this purose; but, however that may be, they are cerinly useful in many cases which do not involve e "germ theory" at all. They may be emoyed by stone-cutters, to exclude from their ngs the dust which has been shown by Dr. reenhow to be deposited there as a stony grit; colliers, as a preventive of the "black lung" used by coal dust; by printers, as a protection ainst the dust arising from the sorting of type, hich Professor Tyndall says "is very destruce to health." These are but a few out of many ides in which life is shortened by the introection of matter into the lungs that might be sily kept out of them. By the use of cottonol respirators the workmen at these trades uld be enabled to breathe "air more free from spended matters than that of the open street." e following case, mentioned by the lecturer, is urious one: —

Over a year ago I was written to by a Lancare seedsman, who stated that during the seed son of each year his men suffered horribly from tation and fever, so that many of them left his vice. He asked me could I help him, and I gave 1 my advice. At the conclusion of the season s year he wrote to me that he had simply folded ittle cotton-wool in muslin, and tied it in front of mouth; that he had passed through the season comfort and without a single complaint from one is men.

It has been objected to these respirators that cotton becomes wet and heated by the air athed out; but this difficulty has been obvid in a form of the instrument invented by a . Carrick, of Glasgow. Two valves are so anged that the air, inhaled through the cot, is exhaled without passing through it.

Professor Tyndall himself, after many experiuts, has succeeded in devising another form respirator which is specially designed for fire. By its aid they can remain for hours in densest and most pitchy smoke, without the st discomfort. The essential part of this restor is thus described: —

Mr. Carrick's arrangement of two valves, the one for inhalation, the other for exhalation, is preserved. But the portion which holds the filtering and absorbent substances is prolonged to a depth of four or five inches. On a partition of wire gauze at the bottom of the space which fronts the mouth, is placed a layer of cotton-wool, moistened with glycerine; then a thin layer of dry wool; then a layer of charcoal fragments; a second thin layer of dry cotton-wool, succeeded by a layer of fragments of caustic lime. The succession of the layers may be changed without injury to the action. A wire-gauze cover keeps the substances from falling out of the respirator. In the densest smoke that we have hitherto employed, the layer of lime has not been found necessary; in a flaming building, indeed, the mixture of air with the smoke never permits the carbonic acid to become so dense as to be irrespirable. But in a place where the gas is present in undue quantity, the fragments of lime would materially mitigate its action.

This respirator was thoroughly tested by Professor Tyndall and his assistants, and also by Captain Shaw, the chief officer of the Metropolitan Fire Brigade of London. A small room was filled with smoke so dense and pungent that a single direct inhalation of it was unendurable, and in this room the experimenters remained for half an hour or more without the slightest inconvenience, and they believed they could have remained there all day.

The conclusion of the lecture was as follows:

"Thus have we been led from the actinic decomposition of vapors, through the tails of comets and the blue of the sky, to the dust of London; from the germ theory of disease down to this fireman's respirator. Instead of this trivial example, I could, if time permitted, point to others of a more considerable kind in illustration of the tendency of pure science to lead to practical applications. Indeed those very wanderings of the scientific intellect which at first sight appear utterly unpractical, become in the end the wellsprings of practice. Yet I believe there is a philosophy embraced by some of our more ardent thinkers (who I fear on many points commit the well-intentioned, but fatal mistake of putting their own hopeful fancies in the place of fact) that would abolish these wanderings of the intellect, and fix it from the outset on practical ends alone. I do not think that that philosophy will ever make itself good in the world, or that any freedom-loving student of nature could or would tolerate its chains."

COD LIVER OIL IN ECZEMA.

A HIGHLY respectable gentleman residing in Charlestown, Mass., writes as follows regarding the use of Cod Liver Oil in this affection: —

I have reason to be deeply grateful for the valuable information with which your journal abounds. My child, 22 months old, has been afflicted with eczema for 19 months. During that time it has received the attention of several skilful physicians, all of whom have pronounced it an uncommonly obstinate case. At the time I read the article on "Cod Liver Oil" in the May number of your journal, the child appeared worse than at any previous time. Its entire body was covered with the eruption. I suggested the use of the oil, dropping other treatment, and the child is now nearly well. Scarcely a trace of the disease remains. This has been accomplished during dentition.

ALCOHOL AND EYESIGHT. — M. Galezowski recently, at a sitting of the Paris Academy of Medicine, pointed out how many cases he had seen among the poorer classes of loss of vision from the chronic use of alcohol. The form of loss of sight is that of amblyopia.

MEDICAL MEMORANDA.

TREATMENT OF CROUP BY INHALATION OF GLYCERINE. — Dr. Stehverger recommends the treatment of croup by the inhalation of pure glycerine through any form of atomizing apparatus. He was led to try this remedy for croup from observing its good effects in case of hoarseness and loss of voice. After application the cough becomes more free and moist, and children are enabled to sleep almost immediately upon being relieved by the inhalation. It is, however, believed to be of importance to make use of the remedy early and frequently, as, if delayed, it may have no effect whatever. If the glycerine be pure, it may be used unmixed; if not, it should be diluted with a little water. The inhalations are repeated, according to the necessity of the case, at intervals of from half an hour to an hour and a half, and for about fifteen minutes at a time. The effect of the glycerine in this case is supposed to be due to the fact that the secretions of the mucous membrane are thereby increased, and tumefaction reduced.

CHLOROFORM IN ROBBERY. — "The availability of chloroform and similar agents in facilitating robbery," was the subject of the lecture delivered before the Medico-Legal Society, of New York, at a recent meeting. Dr. Stephen Rogers, the speaker, took the ground that chloroform cannot be effectively used in aid of robbery, or in stupefying persons against their will for any felonious purpose whatsoever. He believed that no well authenticated case of robbery, effected by means of chloroform, was extant, and cited numerous cases in which burglaries, said to have been effected by its aid, proved afterwards to have been facilitated by the very incorruptible guardians of property who were declared to have been put under the influence of the anæsthetic. He gave it as his opinion that no anæsthetic could be effectively used unless sufficient force were present to hold the subject while the anæsthetic was applied. In the first place, the long time invariably required for the gradual overpowering of the victim would of itself be a great objection to the use of the anæsthetic among thieves. Moreover, the patient always got into a wild state when coming under the benumbing influence. He got into a state of chloroformic intoxication, singing, dancing, and shouting, in a way which would alarm the sleepiest household. Moreover, when in a lethargic state, the patient was seized with violent vomitings, which would be likely to terminate life, if no aid were at hand, adding to the probable danger of detection, and the severity of punishment to the culprit. Even in case of sleep, the choking and retching would probably wake the patient up before the process of stupefaction was complete.

A NEW MERCURIAL PREPARATION. — Dr. Müller, of Breslau, states that corrosive sublimate and chloride of sodium combine to produce a preparation which does not precipitate albumen. Dr. Stern tried the preparation medicinally. Two to two and a half parts of sublimate and twenty to twenty-six of salt are put in 1,000 of water. Sugar and acid drinks are interdicted, as they might destroy the combination. A rather salt diet is best. Out of fifty-four patients only two were salivated by this treatment, which Dr. Stern reports as very effectual in syphilis. As much as from one to two centigrammes of sublimate may be taken in the course of two days without giving rise to gastric disturbance.

CINCHONA IN INDIA. — If the Indian Government have been successful in the cultivation of cinchona bark, they have not been equally happy in their mode of dealing with the product of their plantations. The substance issued by the superintendents of the Darjeeling plantations, for distribution to the hospitals as the product of the bark,

seems to have been of a bright green. As this is not the usual color of quinine or any of the alkaloids of bark, it led to inquiry. The superintendent explained that he had not attempted to isolate the various active principles — quinine, cinchonine, quinidine, etc. — but wished them to employ this extract *en masse*. But when this mixture of alkaloids was analyzed, a very unsatisfactory explanation was afforded of its surprising greenness. It was found to contain 20 per cent. of the poisonous carbonate of copper. If it had actually been used in ordinary doses for the patients, poisonous effects could not have failed to follow. The operators had shown considerable skill in bringing into solution the copper of the vessels which they had employed. On investigation it appeared that the delicate operations involved in the manufacture of the alkaloids had been entrusted "to a European gardener assisted by Booteah coolies!"

Hypodermic Injection of Calomel. — The *Revista Clinica di Bologna* relates eight cases of syphilis affecting the eyes, in which Dr. Soresina injected calomel suspended in glycerine. Six out of the eight cases were cured, and the other two somewhat improved. The successful cases included iritis, keratitis, retinitis, and paralysis of the third pair. The case in which the least effect was produced was thought to be due to atrophy of the optic nerve.

The Replanting of Teeth. — Most persons who have had teeth filled would probably have considered it a relief to have the carious molar taken out, filled, and put back again, instead of keeping the mouth on the stretch, while the dentist worked upon it *in situ*. It appears from the following paragraph, which we take from the *Pacific Medical and Surgical Journal*, that there is some hope that the process of filling may come to be performed in this very way: "Dentists are now testing a plan proposed by Mr. Coleman, an English dentist, as follows: Extract the tooth, clear away caries and the contents of the pulp cavities and canals, wash out with carbolic acid, fill the canals with cotton dipped in carbolic acid, fill the cavity, scrape off all diseased periosteum and cementum, leaving the healthy portions of the mucous membrane attached to the neck of the tooth; bathe alveolus and the tooth in a solution of carbolic acid, and return the tooth to its socket. Out of fourteen cases Mr. Coleman succeeded with nine; operating on bicuspids and molars."

The Nature of Life. — A Philadelphia journal refers as follows to one of the "new lights" of "protoplastic" science: —

"Professor Poey, of Lycoming County, in this State, has been trying to tell us what 'life' is. According to Poey, 'Life results from a double molecular motion, general and continuous, of composition and of decomposition, in relation to the organism and the inorganic medium. The medium is the combination of external agents, physical and chemical, proper to furnish to the organism the principles necessary for its nutrition, and the manifestations of the properties of the anatomical elements.'

"Strange how Error fastens itself in the human mind, and by its rank growth chokes the tender plant of Truth! During all the fourscore years of our existence we have cherished the fond delusion that Life was rather an immorigerous outgrowth of a retiary paradox, which engrafted upon the persiflage a mephitic diapason, causing it to permeate the neurosthenic rhomboid, and so producing isothermally protoplastic vitality. That is what *we* thought life was. But we see the mistake now, since Poey mentions it! It is hard, though — very, very hard — to see the idols of our youth thus thrown down and broken one after the other. And by a man named Poey, too!"

VALUABLE FORMULÆ.

A New Styptic. — Collodion, 100 parts; carbolic acid, 10 parts; tannin, 5 parts; benzoic acid (from gum), 5 parts.

Mix the ingredients in the order above written, and agitate until perfect solution is effected. This preparation has a brown color, and leaves on evaporation a strongly adherent pellicle. It instantly coagulates blood, forming a consistent clot, and a wound rapidly cicatrizes under its protection.

Bromide of Potassium in Intermittent Fever. — Repeated trials in Guy's Hospital have shown the very great value of the bromide of potassium, given in ague. The following formula is recommended: —

℞ Bromide potassium . . . . ʒv.
Tr. cinchonæ, yellow . . . ℥iijss.
Spts. ammoniæ aromat. . . . ℥ss. M.

S. A teaspoonful in half a wineglassful of water, three times a day.

Carbolic Acid in Flavus and Crusta Lactea. — Dr. F. K. Bailey highly recommends (*Nashville Journal of Medicine*) the following formula for these diseases: —

℞ Hyposulphite sodæ . . . . ℈j.
Carbolic acid . . . . grs. v.
Aquæ . . . . . . ℥i. M.

S. Apply to eruptions three times a day. Should the stools be green and slimy, and bowels disordered, he gives the one twentieth of a grain of proto-iodide of mercury, morning and night.

Local Application to Burns. — Dr. Binikerd (*Med. and Surg. Reporter*) applies to burns, when seen early, carbolic acid and glycerine in the proportion of from 5 to 10 drops of the former, to ℥ii. of the latter. This is spread upon the burn by camel-hair pencil or feather, then a layer of white cotton retained by a roller bandage. For the suppurative stage, he employs the following: —

℞ Yellow wax melted and strained . . . ʒi.
Raw linseed oil . . . . ʒiij.
Tannin . . . . . . ʒj.
Subnitrate bismuth . . . . grs. xx. M.

First melt the wax, add the oil, and stir the whole; then add the tannin, and lastly the bismuth. The ointment should be applied on pieces of lint.

Carbolic Acid in Scarlet Fever. — Dr. Cleaver (*Iowa Medical Journal*) has used the following formula with decided advantage in this disease: —

℞ Carbolic acid . . . . . ℥ij.
Alcohol dilute . . . . . ʒij. M.

S. Mix a teaspoonful of this to a tablespoonful of water, used either as a gargle or with a mop, depending upon age and ability to gargle — say once every two hours. Also give ten to twenty drops of same in muc. g. acaciæ at same intervals — dose depending upon age of patient. This treatment was employed in 70 cases, with the most marked success.

Solution of Santonin. — Dr. John Harley, in *The Practitioner*, gives the following formula for a solution of this ordinarily insoluble remedy: —

℞ Santonini, in pulvere . . . grs. xij.
Sodæ bicarbonatis . . . grs. xx.
Aquæ destillatæ . . . . f℥iij.

Put the soda and water into a flask, keep the fluid near the boiling point, adding, as it disappears, about two grains of the santonin at a time, until the whole is dissolved. Solution is effected in about half an hour, during which time the water is reduced to f℥ij. If need be, reduce by boiling to this bulk, when f℥i. will contain a full dose, — six grains of santonin. If an alkaline reaction be objectionable, neutralize with acetic acid.

FRENCH COMMUNISM FROM A MEDICAL POINT OF VIEW.

M. Francisque Sarcey reports in the *Gaulois* a conversation he has had with "an illustrious physician who had left Paris for a few hours, and was about to return," and who expressed the opini that one of the chief causes of the terrible sce which accompanied the final suppression of t Communist outbreak was "a contagious men alienation." The minds of the Parisians, he sa were gradually unhinged by the privations of t siege. The revolt of the 18th of March gave t last blow to brains which were already shaken; a at length the greater part of the population w raving mad. "This epidemical insanity is one the most surprising cases that physiologists ha ever witnessed. . . . You are astonished seeing women, young girls, and children throw p troleum and lighted matches into private hous This fanaticism is attributed to their having be paid ten francs a day for their horrible work. C anything be more improbable than that they sho expose themselves out of mere thoughtlessness the almost certain prospect of being shot down our troops for such a miserable sum? They w simply under the epidemical influence of the ma of incendiarism. . . . They acted under a h lucination which is as incontestable as it is diffic to understand and explain. This is not the fi time that a whole population, attacked by a sort vertigo, ran about with torches and set fire to ever thing in their way. The records of the Middle Ag are full of similar examples. . . . Women a under such circumstances fiercer and more reckle than men. This is because their nervous system more devoloped, their brains are weaker, and th sensibilities more acute than those of the strong sex; and they are consequently far more dangero and do much more harm. . . . None of the knew exactly what they were fighting for; th were possessed by one of the various forms of t religious mania — that which impelled the Jansenis to torture themselves, with a strange delight in pa of the acutest kind. . . . The men who thre themselves on the bayonets of the soldiers in a p oxysm of passion were seen ten minutes after utter prostrate and begging for mercy. They were r more cowards in the last state than they were h roes in the first; they were simply madmen. . . Look at the citizens who did not take part in t insurrection; they are immovable and stupid, li men struck with paralysis. Yet they have on man occasions given proofs of uncommon vigor and cou age; but the air of Paris is at this moment poi oned by deleterious miasmata which make so people furious madmen and others helpless idiot I have seen the strongest intellects stagger und this pernicious influence, and I have myself fr quently felt as if my reason were going."

FAMILIAR EQUIVALENTS FOR METRI WEIGHTS AND MEASURES.

Weights. One milligramme is equal to $\frac{1}{64}$ grai nearly; one centigramme is equal to $\frac{1}{6}$ grain nearl one decigramme is equal to $1\frac{1}{2}$ grains nearly; on gramme is equal to $15\frac{1}{2}$ grains nearly; one dec gramme is equal to 154 grains nearly; one hect gramme is equal to 1,543 grains nearly; one kil gramme is equal to 15,432 grains nearly.

Measures of Capacity. One millilitre is equa to $15\frac{1}{2}$ grain-measures of water; one centilitre i equal to 154 grain-measures, or 3 fluid drams nearl one decilitre is equal to 1,540 grain-measures or 3 fluid ounces nearly; one litre is equal to 15,40 grain-measures, or $2\frac{1}{10}$ pints nearly; one cubi centimetre of water at its maximum density weig $15\frac{1}{2}$ grains nearly, and is $\frac{2}{7}$ths of a fluid dra nearly.

Measures of Length. One millimetre is equal t $\frac{1}{25}$th inch nearly; one centimetre is equal to $\frac{3}{8}$th inch nearly; one decimetre is equal to $3\frac{9}{10}$th inches nearly; one metre is equal to $39\frac{1}{3}$ inche nearly: $\frac{91}{100}$ths metre is equal to 36 inches, or 1 yard nearly.

Boston Journal of Chemistry.

VOLUME VI. BOSTON, SEPTEMBER, 1871. NUMBER 3.

Familiar Science.

THE GREAT MYSTERY.

THERE are many mysteries connected with e natural world which may justly be termed eat, but there is one class of phenomena which of a nature so deeply mysterious that it may ll be called the great mystery. It is now at-acting public attention to a large extent, from e circumstance that three eminent scientific ntlemen of England have recently attempted to vestigate it, and after devoting considerable time the matter, have published some extended state-nts of an important nature. Prof. Crooks, the inent chemist, and editor of the London *Chem-al News*, Mr. Huggins, whose spectroscopic and tronomical researches have rendered his name mous in the scientific world, and Mr. Sergeant x, a prominent member of the English bar, ve had Mr. Home, the "medium" so called, in eir hands and under their control for a consid-able time, and have made, in connection with m, a large number of experiments with the ew of discovering the nature of his "tricks," the source of his extraordinary powers.

The conclusions reached by these eminent entific gentlemen are not surprising or disap-inting, inasmuch as we were certain when the vestigation was entered upon that they would brought in contact with phenomena which ey could neither understand nor explain. The st important conclusion reached is, that the hts, sounds, and physical disturbances generally, ich are produced in connection with Mr. Home, *no tricks of his devising*, and that he is not an postor or charlatan, as is charged by many. . Crooks and Mr. Huggins claim to believe t there is an element of force surrounding or veloping the human organization, which is of raordinary nature, and capable of accomplish-g marvellous things. But all this explains thing. The terms used by the gentlemen in tting forth their theory are as meaningless as e sentences in which they are found, and so as the nature of the mystery is concerned, are as much in the dark as ever.

The truth is, the men known or recognized as entific investigators are no more competent investigate or explain this mystery, than rewd men from other classes, or other pursuits life. Gentlemen devoting their lives to scien-tc research acquire habits of close observation, d are usually ingenious in devising mechanical d other aids for the elucidation of the princi-es and laws of nature, and hence are prop-y regarded as teachers in matters of sci-ce. But the phenomena exhibited through e man Home, and hundreds of others in ferent parts of the world, manifestly do not within the domain of any of the sciences, and nsequently, scientists have no data, no experi-ce, no precedent upon which to base investiga-ns.

During the past quarter of a century we have many times been called to investigate phenomena corresponding with those which have recently come under the notice of Messrs. Crooks, Huggins, and Cox, and we confess to have been baffled and confounded by what we have seen and heard. Probably few experimenters have had a wider, or a more diversified experience in the various departments of scientific research, and in the mechanical arts, and yet we have found no appliances, no experimental tests, which afforded any clue to the mystery.

It is believed by a very large number of men and women in this and other countries, that the physical disturbances and extraordinary phenomena connected with light, sound, etc., are produced by "spirits" or disembodied intelligences from an unseen world. We certainly have no way at present of proving to these persons that their views are erroneous, and we cannot engage in any controversy upon the subject. Our knowledge of "spirits" and their capabilities is very limited, and until we can secure some insight into the actual condition of things beyond the "dark river," we prefer to believe that the phenomena are somehow, or in some way connected with life in this mundane sphere.

Contradictory, uncertain, capricious as the phenomena generally are, they yet seem to be governed by some laws or conditions, which if not fixed, approximate to that condition. "Mediums" tell us that they have no control over the demonstrations, that they appear and disappear independent of their wills. This is virtually saying that the phenomena are spontaneous, or independent of human volition, and such appears to be the case. It is certain the "tricks" are not absolutely at the command of any one. We have waited with much impatience for hours in the houses of friends for the demonstrations, and it was not until we were upon the point of departure, that the strange antics commenced. In these instances the impatience, desire, and anxiety of the family, whose guest we were, were greater even than our own. We do not know why this is so, in fact we know nothing whatever about it. But this affords no reasonable ground for concluding that we shall always remain in ignorance. An electrical machine, put in the best possible condition, refuses to afford sparks and reports when worked in a damp atmosphere, but transport it to a cool and dry one, and the most brilliant phenomena are at once witnessed. If we originally constructed the machine, and had many times witnessed its capabilities, but were ignorant of the fact that certain meteorological conditions were necessary to success, we might summon our friends to an exhibition on a wet night, and utterly fail to produce a spark. If the visiting parties had never seen an electrical apparatus, and the experiments were new, they would leave the house, as do the disappointed wonder-seekers the rooms of "mediums," convinced that "the whole thing is a humbug." It is the ignorance of the conditions upon which the phenomena depend that leads so many to regard them with suspicion and distrust. Whenever we understand the laws under which this strange power acts, then we may be able to experiment at will, and subject it to careful study.

Manifestly there are invisible, imponderable agencies of great power in this world, other than those which modern science recognizes, and it is a source of no little annoyance and mortification that thus far we have failed to bring them within the field of scientific investigation. At present the whole matter is involved in doubt and perplexity, but we have faith to believe that a future age will find means to solve the great mystery, and roll away the dark clouds which obscure our vision.

THE SPECTROSCOPE IN CHEMICAL ANALYSIS.

THE spectroscope has attracted a great deal of attention within a few years, principally from its use as a means of astronomical research. Its more obvious use as a method of chemical investigation seems to have been very much overlooked, and many of our text-books on qualitative analysis either ignore it altogether or merely allude to it in a superficial way.

Having used the instrument for several years both in our own work and in instructing students, we think our experience will not be without interest.

We have tried several forms of instruments, with prisms varying in number from one of flint glass to six of bisulphide of carbon, and as the result of these trials we have concluded that an instrument furnished with good telescopes and a single flint glass prism is all that is necessary for chemical use. A piece of apparatus that requires much adjustment or delicate manipulation is altogether out of place in the laboratory. The best of the single prism instruments that we have ever seen is the one manufactured by Alvan Clark, of Cambridge. It is light, portable, easily changed from a position in which the lines are vertical to one in which they are horizontal. The prism and telescopes are all rigidly fastened to a brass box, so that there is no liability of displacement. All the spectrum is in the field at once, which is a great advantage for ordinary work. For use in iron works or other metallurgical operations, it can be readily detached from its stand, and either held in the hand or attached to a convenient post.

A common fault with the ordinary spectroscopes is, that they are made too small in all their parts. We should prefer for our own use, — were it not for the expense, — an instrument which had telescopes of two inches aperture, although those of one inch aperture do very good work. But with the large instrument we have

been enabled to detect potassium and rubidium in substances in which our small instrument did not show a trace.

The scales with which almost all spectroscopes are furnished are of but little use except to the beginner, and we have even then found them to be of a positive disadvantage. The eye may soon be educated to know the relative places and the colors of the lines given by the various elements. It is much less liable to err than when an arbitrary scale is used that may become displaced. The sodium line is always present, and serves as a standard of reference. The scales on no two instruments that we have ever seen were precisely alike, and therefore in referring to scale numbers it is always necessary to reduce them to some known standard. For chemical work it is generally sufficient to speak of a line as being near some other well-known line.

The elements most easily detected are sodium and lithium, the sodium giving its characteristic yellow line. Lithium gives a bright red line half-way between the potassium line and the sodium line. The potassium line is at the extreme red end of the spectrum; potassium gives another line in the violet, but this can only be seen when the light is very strong and the substance is nearly free from other elements. The characteristic lines of cæsium are two bright blue ones; this metal has also a number in the red which are only seen under favorable circumstances. Rubidium gives two dark red lines which are almost coincident with the potassium red, and are therefore of little value as a means of identification; it also gives two violet lines intermediate in position between the potassium violet and cæsium blue; these are the most characteristic. Strontium has a number of green, orange, and red lines, none of them being very characteristic, but it has a single line in the violet which is very characteristic. Calcium gives a broad orange band on one side of the sodium line and a green band on the other side. Barium is distinguished by a great number of lines in the green, some of them being very near the blue portion of the spectrum.

Many minerals will not give the lines of the elements which they contain without some previous treatment. Some of these may be analyzed by taking a small fragment in a coil of platinum wire, heating it red-hot, and dipping it into hydrochloric acid; it is then placed in the burner before the slit of the spectroscope. A few repetitions of this process will generally enable us to detect calcium and potassium in a feldspar. If this method fails we can replace the hydrochloric acid by hydrofluoric; this succeeds very well with mica.

For the detection of the traces of the rarer elements that exist in some minerals, we must first adopt some means of concentration. We have been very successful in detecting cæsium and rubidium by treating the mineral with hydrofluoric acid mixed with an excess of sulphuric acid. The pasty mass is evaporated to dryness and then ignited until all the hydrofluoric acid and silica are driven off; the residual mass is boiled with water with the addition of a little sulphuric acid. The solution obtained is filtered from any residue that may remain, and mixed with a solution of aluminic sulphate. It is then evaporated until it commences to crystallize; the first crystals deposited will contain rubidium and cæsium; these may be redissolved and recrystallized several times, and then examined with the spectroscope. Cæsium is most readily detected by adding to the original solution, which should be concentrated to a small bulk, a solution of stannic bichloride, and then a large excess of hydrochloric acid. The cæsio-stannic chloride is precipitated in large crystals which are almost pure. An examination with the spectroscope will confirm the presence of cæsium. Thallium is found in many specimens of pyrites. It may often be detected in the flue dust from furnaces in which coal containing pyrites is burned. The readiest method of detecting it is to treat the suspected dust with nitric acid, evaporate to dryness to get rid of the silica, and then add a little nitric acid to the mass and filter. The filtrate is treated with hydrosulphuric acid, and the precipitate, if one is formed, is examined with the spectroscope. Thallium gives a very characteristic line in the green. Indium is found only in combination with zinc. It may be detected by dissolving the dust from the prolonges in hydrochloric acid until the acid is saturated, and then inserting a strip of metallic zinc in the liquid. If indium is present it forms a black coating on the zinc. This should be examined by the spectroscope for the indigo line of this element.

GEYSER SPRINGS, CALIFORNIA.

BY E. CUTTER, M. D.

I LEFT San Francisco for this place on Monday, the 8th inst., at 4 P. M., by steamboat for Vallejo. I then took cars and rode 38 miles, to Calistoga — the Saratoga of this coast. Here I slept till morning. I rose early; found the place situated in a lovely valley green with rich verdure. The hotel consists of a pavilion for eating, offices, etc., while scattered about are a large number of beautiful cottages, commodious, isolated, and very nicely fitted up. Around the area of the domain are various sulphur springs. One, in front of the hotel door, appeared to be down in a sort of stove funnel. I dipped in a tumbler, and on tasting came near burning my lips, it was so hot, but innocent-looking! There were besides a large number of sulphur springs, some steaming like a boiling cauldron. These are arranged to give steam and mud baths, and are probably quite useful in rheumatic affections. At 7 A. M. our party started in wagons for this place. It numbered about fifty. It was the largest party that ever went over the road at one time, except one. We rode 28 miles, and arrived here at 2 P. M. The route was over a mountain road, built two years ago by Chinamen in four months' time. It excels the White Mountain driveway. I think I never went over a more "skittish" road. After arriving at the summit of the mountain, our way was down steep grades cut in the sides of the ranges. On the left you could not see the top of the mountain, and on the right you could look down dizzy, almost perpendicular heights of 500 to 1,000 feet. Added to this the horses cantered down at a good speed, and sometimes the turns were so short that it seemed as if we should tip over. A man named Foss is the famous Jehu of this coast. He is a sort of D. D. Hart, and of equal physical proportions. He drives six horses. Stories are told of him that are appalling. For instance, he drove down a mountain road to this place, — not the one we came, but a worse, — a distance of two miles, in seven and a half minutes, descending 1,900 feet in that time! He whipped his horses down the incline, and yet accomplished the journey in safety. It is a big story, but I believe it is true.

The Geyser hotel is peculiar in that it has no plastering — the ceiling is made of canes, whitewashed. This is a remarkable place. It is hard work to describe it, but I will make an attempt. Imagine a deep cañon or gully cut from east to west in a mountain country. Its depth is 3,000 feet; its width at the top three miles. In this cañon flows the Pluton River noisily. Just opposite the hotel, which is on the south side of the cañon, there is another gulley running from the north at right angles to the great cañon. This is the seat of the most wonderful collection of natural chemical phenomena in the United States. You go down from the front of the hotel, and stop at a sulphur and soda spring. The guide scrapes off the scum from its surface, dips in a cup, and you drink a nasty warm liquid. Passing on over the Pluton you enter the secondary cañon. The first they show is the Devil's Office, a grotesque space hollowed from each side and covered with trees. Gypsum salts in crystals adorn the sides. Now you smell the sulphur. As you go on, you come to boiling hot springs of alum, iron, copper, and lead. The surface of the ground is spongy and hot, so as to be uncomfortable. You see black ink springs, green crystals of copperas, white of Epsom salts. Underneath you are noises of boiling liquids, sounding like a large machine shop at work. This is the Devil's Workshop. Here and there are excavations called the Devil's Nose, Ear, and Mouth. The latter is a sputtering, stinking, seething, and steaming cavern, fitly named. Red, green, yellow, and white incrustations abound, while the presence of free sulphurous acid and ammonia gives an odor which is not pleasant. Further on is the Witch's Cauldron — a cavity seven feet in diameter and of unknown depth, filled with a dirty black liquid at a temperature of 220° Fah. — an awful place; seething, bubbling, boiling, steaming — sure death by scalding to fall there. The ground is spongy and hollow; you can easily run a cane in three feet anywhere, and the hole will smoke on withdrawal. Beyond were the Steamboat Geysers, fitly named, belching forth a steam-cloud forty feet high, and singing like a steamboat. At the upper end was the Devil's Pulpit, a high projection, from which you can look through the whole cañon and have a fine view. In the vicinity is a well marked crater of an extinct volcano. Near by is seen a torrent of scalding steam, called the Indian Sweat Bath. Altogether the Geysers are a deeply interesting evidence of the internal heat of the earth. You don't feel safe near them. They may burst out any day.

DIAMONDS.

IN a lecture which Professor Tennant, of King's College, gave several years ago before the Society of Arts in London, he stated the principal object of his lecture was to point out the means of distinguishing artificial stones from real ones, and of discriminating between a precious stone of one kind, and another. One means of doing so was by knowing into what figures

e different gems crystallized. The diamond, · instance, assumed various geometric figures, t it was remarkable that it was never found as six-sided *prism.* Had this been known, the lowing incident, which Professor Tennant re-ed, would not have occurred: —

"A person was offered £200 for a stone hich the lecturer exhibited) that he had ked up in California, under the impression it it was a diamond; and the possessor of it, ing under the same opinion, refused to part th it for that sum. It was a six-sided prism; minating in a pyramid at each end. Neither them knew that diamonds never assumed that m, and accordingly the one refused the £200 ered by the other, for what was only a piece crystallized quartz, not worth more than half rown."

But an equally simple and conclusive test uld be the specific gravity of the stones. In Russian department of the Exhibition of 151, was a beautiful blue stone. Much doubt s entertained of its nature. On one occasion eral scientific gentlemen were brought to ex-ine it. Almost every gentleman present gave different opinion as to the real nature of the ne; only one called it by what turned out to its real name. The proprietor maintained it s a blue diamond, and offered to submit it to y test that might be suggested. Professor nnant suggested that the simplest and safest t would be to ascertain its specific gravity. being allowed so to test it, he weighed it inst a topaz in its natural state, and found the ecific gravity to be precisely the same.

THE UPAS TREE.

A YEAR or more ago, in reply to an inquiry m a correspondent, we gave some facts con-ning this tree, which is far from being the tiferous thing that the fables of the early trav-ers made it.

The tree is found occasionally in other islands n Java, and a writer in *Appletons' Journal* es an account of one in Borneo which he vis-l during the East Indian cruise of the United tes ship *Plymouth.* The following is an ex-t from the article: —

Following our native guide-boat, we sheered in g-side of a grassy bank, the summit of which was out in small plots like children's gardens at e, each plot surrounded by a border of shells, carefully kept walks between them. Nothing grass and flowers were growing there, but these e luxuriant; for this was a graveyard, and we e even then standing under the shadow of the ible poison tree, near which these people bury r dead, which may partially account for the derful stories told by early travellers. The tree f measured eleven feet in circumference five above the ground, and, instead of scattering th and destruction, was girded round with creep-vines and many-colored parasites, that wound r way to the topmost branches, which were ier than any of the surrounding trees, and alled, if not surpassed, those of our loftiest forest s at home.

An incision was made, after the manner of tap-g maple-trees, and the sap, which is reported to a deadly poison, commenced flowing drop by . It was of a yellowish white color, thick and inous, resembling in its general appearance l rich cream. There was no unpleasant odor ceptible from it, nor did any of us experience any disagreeable sensations, though standing near by while the sap was being discharged. This was so slow an operation that it required nearly an hour to fill a half ounce vial. Meantime it was desirable to procure some of the leaves and branches, but these were beyond our reach, as the lowest branch was at least 100 feet from the ground, and although the men could easily have climbed up by the vines, the surgeon in charge of the party refused to let them make the attempt, fearing that their hands and feet might become poisoned."

THINGS WORTH NOTING.

GREEK FIRE. — Modern Greek fire is a solution of phosphorus in bisulphide of carbon. When this solution is poured on paper, rags, or shavings, the bisulphide evaporates rapidly and leaves the phosphorus in a state of very fine division — so fine that it takes fire spontaneously. It furnishes the means of performing a very pretty lecture-room experiment, but, as an incendiary agent, it is worthless, for the simple reason that it does not set fire to even the thinnest and driest boards. The phosphorus, in burning, produces a fusible and non-volatile compound, and this glazes over all objects in its vicinity, and protects them from the action of the flames.

EAU DE COLOGNE. — Competent authorities declare that the excellence of the perfume almost entirely depends upon the purity of the spirit employed as its basis. Spirits made from malt and other materials *not* vinous will never produce Eau de Cologne of a high character, owing, it is believed, amongst other causes, to the odor of fusel oil in the first and to œnanthic ether in the second. Neroli, without which neither genuine Eau de Cologne nor a good imitation of it can be made, is an essence obtained from orange blossoms (the bitter species, *Citrus bigarradia*), and hundreds of tons of flowers are plucked and consumed for the purpose.

SWEEPING CARPETS. — Persons who are accustomed to use tea-leaves for sweeping carpets, and find that they leave stains, will do well to employ fresh-cut grass instead. It is better than tea-leaves for preventing dust, and gives the carpet a very bright fresh look.

TO COLLECT THE ODORS OF FLOWERS. — Roses, and all flowers containing perfumed oils, may be made to yield their aromatic properties by steeping the petals or flower leaves in a saucer or a flat dish of water and setting it in the sun. The petals should be entirely covered with the water, which, by the way, should be soft or rain water. A sufficient quantity should be allowed for evaporation, and the vessel should be left undisturbed a few days. At the end of this time a film will be found floating on the top. This is the essential oil of the flower, and every particle of it is impregnated with the odor peculiar to the flower. It should be taken up carefully and put in tiny vials, which should be allowed to remain open till all watery particles are evaporated. A very small portion of this will perfume glove-boxes, drawers, apparel, etc., and will last a long time.

TO CRYSTALLIZE FLOWERS. — Construct some baskets of fancy form with pliable copper wire, and wrap them with gauze. Into these tie to the bottom violets, ferns, geranium leaves — in fact, any flowers except full-blown roses — and sink them in a solution of alum, of one pound to a gallon of water, after the solution has cooled. The colors will then be preserved in their original beauty, and the crystallized alum will hold faster than when from a hot solution. When you have a light covering of crystals that completely covers the articles, remove the basket carefully, and allow to drip for twelve hours. These baskets make a beautiful parlor ornament, and for a long time preserve the freshness of the flowers.

HOUSEHOLD RECIPES.

RASPBERRY JAM. — Let the raspberries be thoroughly ripe. Mash them with a wooden spoon. To every pound of raspberries add a pound of sifted sugar. Boil well half an hour, stirring it continually, lest it should burn. When of a good thickness, put it into pots, let it cool thoroughly, and cover with brandied paper.

BLACKBERRY JELLY. — Gather the fruit when perfectly ripe, and in very dry weather. Put the blackberries into a jar and place the jar in hot water, keeping it boiling until the juice is extracted from the fruit. Pass it through a fine sieve or jelly-bag without much pressure. For every pint of juice add fourteen ounces of sugar, and boil in a clean preserving-pan about five and twenty minutes, carefully taking off the scum as it rises to the surface. Place it hot in small jars and cover it with thin tissue-paper, dipped in brandy, and brown paper over it. Keep it in a cool, dry place.

RASPBERRY VINEGAR. — A very superior raspberry vinegar is made by taking three pounds of raspberries, two pints of vinegar, and three pounds of sugar. Put the raspberries into the vinegar without mashing them, cover the pan close, and let it remain in a cellar for seven or eight days; then filter the infusion, add the sugar in powder, and finish in the water-bath. It is an advantage of this process that the beautiful aroma of the fruit is not lost, as it is by the ordinary method of boiling.

A SUBSTITUTE FOR MILK OR CREAM. — Beat up the whole of a fresh egg in a basin, and then pour boiling tea over it gradually, to prevent its curdling. It is difficult from the taste to distinguish the composition from rich cream.

SOFT CHEESE. — Take milk just as it begins to turn sour; pour over it about one fourth its bulk of scalding water, beating the milk with a spoon at the same time to cause the whey to separate. Then strain off as much of the liquid as possible, finally washing the curd with clean water. Add a little salt, and you have a palatable and very nutritious article of food.

A GOOD BREAKFAST DISH. — The following is as good as it is easy to prepare: Take four eggs, three quarters of a pint of new milk, and a piece of butter the size of a walnut: salt (and pepper it if you like it) to suit the taste. Beat the eggs, add the milk and butter, and pour all together into a hot frying-pan containing half a spoonful of lard or butter. Stir constantly for three or four minutes, when it will be ready for the table.

MOCK VENISON OF CORNED BEEF. — Cut the beef in thin slices, and freshen by soaking for three or four hours in tepid water. When sufficiently fresh, lay the slices on a gridiron, and heat through quickly. Make a gravy of drawn butter; add a little pepper, and the yolk of an egg chopped fine, and pour over the meat; or butter, pepper, and salt, like beefsteak. This will be found a savory dish when only salt meat can be procured, but it is better with fresh beef.

OUT OF THE DEPTHS. — A remarkable illustration of the power of modern science to wrest spoils from the depths of the ocean is now afforded at Galle Head, on the Irish coast, off which point the *Crescent City* sunk some months ago. The diving operations have been so conducted that $10,032 in specie have been recovered, together with four hundred and sixty bales of cotton, valued at $55 per bale. It is expected that the whole of a valuable cargo, both specie and cotton, will be recovered.

According to the Virginia papers, the powder-tanks found by the wreckers in the Confederate iron-clad *Richmond*, now lying in thirty or forty feet of water off Chapin's Bluff, are in good condition, and the powder as dry and ready for use as before its submersion six years ago.

The Arts.

THE FIRST PHOTOGRAPHER.

It has been generally taken for granted that the discovery of photography dates back only to the year 1839, when Daguerre in France and Talbot in England published the results of their investigations. It appears probable, however, that the art was discovered and practically applied by Matthew Boulton, partner of the celebrated James Watt, as long ago as the close of the last century, and was then allowed to fall into neglect, and to be forgotten. Boulton belonged to a secret scientific society, which was accustomed to meet at his house. He died in 1809; and, on the subsequent examination and removal of the vast collection of documents stored in his library, there were found a number of crumpled and folded sheets of paper with pictures on them of the most puzzling kind. On smoothing out these pictures, they were found to consist of copies, on large sheets of very coarse paper, of certain well-known designs by Kauffmann — the porous water-marked paper being thickly coated with some varnish-like substance, on the surface of which the picture had been produced. All the sheets found in the library, as well as others afterward discovered, presented the same characteristics — a glossy surface, with minute varnish-like cracks, the drawing of the figures most elaborately finished, the lights and shades so fully rendered as to give much the effect of a mezzotint, and an invariable reversal of the position of the figures. Further research also led to the discovery of two silver-metal plates, about the size of a sheet of note paper, precisely resembling in appearance those used by Daguerre in the early days of photography. On each of these plates was a faint image of Boulton's house, so unmistakably taken from nature, and so evidently produced by the aid of light, that experts at once pronounced them to be photographic pictures, taken directly by means of a camera. Attached to these plates was a memorandum stating that they were "sun pictures," representing the house prior to certain alterations made in 1791. All these facts lead to the inevitable conclusion that the discoveries of Daguerre were anticipated by Boulton. Watt, as is well known, was the true father of the steam-engine, which in his hands first became a machine of real practical value; and it is a curious fact that a discovery of almost equal importance, in a wholly different field of scientific research, should have been made by the man associated with him as a partner in business.

NON-INFLAMMABLE DRESSES.

Scarcely a season passes that we do not hear of injury to some unfortunate girl, whose dress has caught fire and instantly wrapped her in flames. The fall of a lamp, the coming too near to an open fire-place, the careless use of matches, and many other apparently trivial causes, have produced accidents which have resulted in death. The footlights of the stage and the rostrum have, in this way, caused injury and death to thousands.

With a desire to mitigate the evils arising from this source, Queen Victoria some years ago commissioned the late Professor Graham, then Master of the Mint, to investigate the subject for the purpose of selecting some means whereby, without injuring the quality or appearance of the fabric, the material of most dresses might be rendered uninflammable, if not incombustible. Professor Graham confided the investigation to the care of Dr. Oppenheim and Mr. Frederick Versmann, whose elaborate report on this subject deserves the most careful attention.

Of all the salts experimented upon by these gentlemen, only four appear to be applicable to light fabrics. These salts are, 1, phosphate of ammonia; 2, a mixture of phosphate of ammonia and chloride of ammonium; 3, sulphate of ammonia; 4, tungstate of soda. The conditions required to be fulfilled in this case are, 1, that the salt shall not injure the strength of the fabric; 2, that it shall not stain or interfere with the color; 3, that it shall not leave the fabric when the latter is washed, or, if this be the case, that it shall be easily applied in the laundry; 4, that it shall not interfere either with the character of the finish or with the ease with which this finish is produced; 5, that it shall be cheap; 6, that it shall be efficient. No salt was found that would adhere to the fabric and bear washing without injuring the color. Salts of tin, it is true, could be applied so as to bear washing and yet remain efficacious, but their action upon the color unfitted them for all but the coarsest fabrics. The phosphates are efficient, but unfortunately are too expensive. The sulphate of ammonia is by far the cheapest and most efficacious salt, and it was therefore tried upon a large scale. Whole pieces of muslin (eight to sixteen yards long) were finished, and then dipped into a solution containing ten per cent. of this salt, after which they were dried in the hydro-extractor. This was done with printed muslins as well as with white ones. They had a good finish and none of the color gave way, with the exception of madder purple, which became pale. But even this change may be avoided, if care be taken not to expose the piece while wet to a temperature higher than ordinary. Unfortunately, however, sulphate of ammonia is not adapted for use in the laundry, as it acts on the irons and produces spots of iron-mould. This might perhaps be avoided by covering with paper or cloth the article to be ironed, but this device is not always available; so that, on the whole, tungstate of soda is the only salt that can be recommended for family purposes. After having tested various salts and solutions intended for the purpose, this is the only one found to be neither injurious to the texture or color, nor in any degree difficult of application in the washing process. The iron passes over the material quite as smoothly as if no solution had been employed. The solution increases the stiffness of the fabric, and its protecting power against fire is perfect. This salt offers only one difficulty, namely, the formation of a bitungstate, of little solubility, which crystallizes from the solution; but it was found that a very small percentage of phosphate of soda rendered the tungstate quite stable. The best way to prepare a proper solution is to dilute with water a concentrated solution of the tungstate until it indicates 28° (spec. grav., 1.140) and then mix it with three per cent. of phosphate of soda. The goods are moistened with this solution just before being starched, and they may be afterwards ironed and finished without the least difficulty.

Articles prepared in this way are perfectly uninflammable. They may be charred by exposure to fire, but they do not burn readily unless there is some extraneous source of heat, and they cannot be made to burst into flame. By aid of this discovery, a lady, dressed in the lightest muslin, might walk over a row of footlights, and the only result would be that the lower part of her dress would be injured. Unless her person actually came in contact with the gas flames, she herself would suffer no injury.

It is estimated that America, when her productive power is fully developed, will be able to feed four times as many persons as there are now on the face of the earth.

ELECTRICAL RAILWAY SIGNALS.

A perfectly trustworthy system of railway sign[als] has long been a desideratum; and Robinson's inv[en]tion, recently patented, appears to supply the wa[nt]. The apparatus works automatically, and works [so] effectively that a switchman or engineer, drunk [or] asleep, cannot evade it. A train approaching [a] switch or drawbridge in either direction, when d[is]tant a half-mile, more or less, will press upon a le[ver] arranged in proximity to the track. This le[ver] controls an electric circuit, which, being closed [by] the train, remains closed. When the switch [or] drawbridge is in place, and safe, a white flag [is] brought into view in a signal-box placed by the si[de] of the track, a short distance in advance of the lev[er] — thus notifying the engineer that he can go ahe[ad] without danger. When, however, the switch [or] drawbridge is out of place, the pressure of t[he] wheel on the same lever as before, brings into vi[ew], in the same signal-box, a red or danger signal, a[nd] rings two bells loudly at the same time — one at t[he] signal-box, and one at the misplaced switch [or] drawbridge. These bells keep up a continu[ous] alarm until the wheels pass another lever, whi[ch] operates a circuit-breaker, located at a short dista[nce] from the switch or drawbridge.

As will be perceived at once, the engineer, [by] this arrangement, cannot fail to be positively [in]formed of the exact condition of the switch or dra[w]bridge which his train is approaching, while t[he] switchman, also, is informed when a train is a[p]proaching an open switch, and warned to close t[he] same. As the whole operation is automatic — t[he] passing train closing and opening the circuits, a[nd] operating the signals — the safety of a train is [n]ot left to a possibly negligent or perhaps intempera[te] watchman. The bell can be heard at the distan[ce] of a mile.

MEMORANDA IN THE ARTS.

Explosive Harpoons. — A correspondent [of] *Land and Water*, who has been on a trip to No[r]way, gives an account of the whaling establishme[nt] of Herr Foyen, in the Veranger Fiord. He emplo[ys] two small steamers of about seventy tons eac[h]. The special apparatus used consists of a harpoo[n] inclosing in its head half a pound of gunpowde[r], and with jointed or hinged bars containing so[me] percussion-powder between them. When the wha[le] is within gunshot, this harpoon, attached to the e[nd] of a long cord coiled around a drum, is fired in[to] the animal from a cannon about the size of a fou[r]-pounder. As the flukes penetrate the side of t[he] whale they are naturally brought together [and] pressed down towards the shaft, and in so doin[g] ignite the percussion-powder, which sets fire to th[e] gunpowder, causing an explosion in the body o[f] the animal that usually produces a mortal woun[d]. The whale, of course, starts off under the stimul[us] of the pain, and the rope is carried out for a tim[e], being uncoiled from the drum precisely like a fis[h]ing-line from the reel of a fishing-rod, the steame[r] following after so as to prevent any undue strai[n]. If necessary, a second discharge takes place, whic[h] almost invariably produces death.

Petroleum Fuel for Locomotives. — I[n] France, a model engine heated by petroleum ha[s] been exhibited, which appears to be a complete suc[]cess. This locomotive carries 2,000 litres, or abou[t] 500 gallons of oil in the tender, a hand pump forcin[g] the oil into a small reservoir near the boiler. Th[e] process of lighting the oil is said to be neither dif[]ficult nor dangerous, owing to the oil being kept i[n] compartments, a small quantity only being lighte[d] at one time, then another division, and so on, unti[l] the whole furnace is alight. This engine consume[s] its own smoke perfectly, and it is said to be ex[]tremely easy to drive, on account of the simplicity of the apparatus. A larger locomotive, with slight

provements, has since been built, and successful als made of its working qualities. The consumption of oil was 35 per cent. less by weight, than that good patent compressed coal.

Leather Guns. — An English paper states that e Cuban rebels have resorted to the use of leather ns, a species of artillery used by Gustavus Adolus and other European commanders in times ar and remote. The leather while wet is tightly tched round a wooden core or mould, in successive ckets, the under one being allowed to dry before e next is put on. A close and tight coil of good pe or cord completes the tube, the breech being de of hard wood, lined with tin. Such guns ll fire some twenty rounds before giving way. eir advantages are cheapness and ease of conuction.

PRACTICAL RECIPES.

To Clean Gilt Jewelry. — Take half a pint boiling water, or a little less, and put it into a an oil flask. To this add one ounce of cyanide of tassium, shake the flask, and the cyanide will disve. When the liquid is cold, add half a fluid nce of liquor ammonia and one fluid ounce of tified alcohol. Shake the mixture together, and will be ready for use. Gilt articles which have come discolored, may be rendered bright by ushing them with the above mentioned fluid. must be borne in mind that the cyanide of potasm is a deadly poison, and should be used with ution.

To make a Good Mucilage. — The best qual- of mucilage in the market is made by dissolving ar glue in equal volumes of water and strong vinar, and adding one fourth of an equal volume of ohol, and a small quantity of a solution of alum water. The action of the vinegar is due to the etic acid which it contains. This prevents the ue from gelatinizing by cooling; but the same sult may be accomplished by adding a small quany of nitric acid. Some of the preparations offered sale are merely boiled starch, or flour, mixed th nitric acid to prevent the gelatinizing.

Red Ink. — To 12 grains of carmine add 3 nces of aqua ammonia, and heat gently, without iling, for seven or eight minutes; then add 18 ains of gum arabic, stirring constantly. It must kept well corked.

Another recipe is as follows: add 2 ounces of powred Brazil wood to a pint of water, and boil it wn to one half the quantity; then add ½ ounce m arabic, 1½ drachms of tincture of cochineal, and ounces of alcohol.

Violet Ink. — Take aniline violet, half an nce, and digest it in five ounces of alcohol in a ass or an enamelled iron vessel for three hours; en add a full quart of distilled water and heat ntly for several hours, or until the odor of the irit has disappeared; then mix in two drachms gum arabic dissolved in half a pint of water, and ow the whole to settle. Experiment will deterne the precise quantity of coloring matter that ll be required.

Gold Bronze. — Pure gold bronze powder may made as follows: Grind leaf gold with pure ney until the leaves are broken up and minutely vided. Remove this mixture from the stone by a atula and stir up in a basin of water; the water ll melt the honey and set the gold free. Leave e basin undisturbed until the gold subsides. Pour f the water, and add fresh instead, until the honey entirely washed away, after which collect the gold filtering pans and dry for use. A cheaper sort ay be made thus: Melt one pound of tin in a ucible and pour it on one half pound of pure merry, when this is solid grind it into powder with ven ounces of flowers of sulphur, and one half und of sal-ammoniac.

Agriculture.

FARM PENCILLINGS AT LAKESIDE.

Those who heard or have read the Address which we delivered before the Massachusetts State Board of Agriculture at Framingham, last December, will remember that we gave the results of our experiments with manures at Lakeside, up to the close of the season of 1870. Considerable interest has been manifested in various quarters to learn regarding the success of the experiment as continued during the present exceedingly dry and unfavorable summer. It gives us pleasure to be able to state that the crops have been good; indeed, we are obliged to say that they have never been so prosperous and abundant, and the success of our treatment of soils is fully established. The position we have always taken has been, that no farm experiments are of any practical value which have not been carried through more than a single season; as different meteorological conditions — such only as are met with in three, four, or five consecutive summers — are needed to establish the reliability of any special or general plan of soil treatment.

Some methods of soil improvement are well enough in a wet season, but continued through a dry one, they fail. The great question we have been endeavoring to settle is, whether fields of ordinary quality, embracing uplands and lowlands, can be put in good tilth, and continued in that state through wet and dry seasons, by the use of fertilizers outside of animal excrement. Having conducted experiments of this nature through eight consecutive seasons, we are now prepared to declare *that they can be*. The season of 1870 was remarkably dry, but the severity of the drought did not commence until the latter part of June, when the hay crop was secure, and hence nothing was learned regarding its influence upon this crop; but the present season its full force was felt in the months of May and June, embracing the period when grass first starts into life and continuing until it reaches full maturity. Scarcely any rain fell in May, the rain gauge indicating less than three fourths of an inch during the month. In spite of this extraordinary drought, we cut in July three and a half tons of cured timothy hay per acre, upon some of our fields which we believe had never received a dressing of farm dung, or animal excrement of any kind.

The increase of our hay crop on the same area this year, over last, has been fully 25 per cent., and the quality has been decidedly better. This increase has not been confined to low lands, but extends to fields which under ordinary conditions feel drought sensibly. The low lands which we seeded to grass last autumn, after thorough spading and pulverization, were put under the scythe as early as the 20th of June, the grass being lodged from heavy growth. The crop was a fine one, and at the time of writing, another crop is ready for the mower, which we think will prove fully as large as that removed in June. This field measures nearly two acres, and one portion was dressed with Peruvian guano, another with fish pomace, another with cow dung. The cost of each was very nearly the same, and the resultant crops did not vary much in value, the fish pomace giving the poorest returns. We place a high value upon Peruvian guano of *standard* quality, when applied to meadow lands. After repeated trials of the fertilizer, extending over a period of six years, we have proved it to have a value deserving the farmer's attention, who has bog lands to reclaim. The price in this city during the past ten years has been excessive, or greater than its actual value for ordinary soil purposes; but the dealers during the past season have been able to reduce it about twenty-five per cent., and this reduction brings it within the possibility of economic use. In recommending this powerful agent, we are met with the same embarrassing circumstances which meet us whenever we call attention to any commercial fertilizer. The matter of the *purity* or genuineness of any specimen is the all-important point to be settled, before purchases are made; and how shall this be met? The only way it can be reached is by securing chemical analysis of each parcel, but this work does not come within the reach of ordinary purchasers, and therefore it must be bought solely upon one's faith in the knowledge and integrity of the vender. That which we have examined and purchased of one party in this city has been found to be remarkably uniform in character, and the nitrogenous and phosphatic principles present gave it a satisfactory or standard value. We presume it can be procured of fair integrity in other cities.

At Lakeside we have this year taken into the barns sixty-seven loads of hay from fields which six years ago did not give twenty, and this result has been brought about by good culture, and the application to the soil of those fertilizing agents which the rich grasses demand. If lands are in good tilth, well drained, and worked, so that air can penetrate into them, dry weather affects them much less than those which are neglected. The advantages we have secured the present season are due to several causes. Upon our well tilled fields the grasses started earlier than upon others, and hence the roots were placed in shade earlier, and the dry winds and hot sun were in a measure prevented from injuring them. The vigor of the plants was sustained after growth commenced by a supply of nutriment, and hence there was no faltering in the process of the growth. The soil bed was comparatively light and porous, so that air, during the night time, when it deposits moisture, could enter and leave the condensed products around the roots of the grasses. It has been proved that concentrated fertilizers like bone meal, dissolved bones, bone and ashes, guano, etc., etc., do not tend to "burn the soil" and increase the evils of drought as many suppose. Our best crops have been taken from fields which have been for years fertilized by no other agents, and we have learned to trust them under all meteorological conditions.

SOUTHERN FARMERS.

Formerly, in speaking of the cultivators of cotton, rice, tobacco, corn, etc., in the Southern States, they were called "planters," and this was the general designation employed throughout the country. Now, the term "planters" has, to a considerable extent, fallen into disuse, and the good old wholesome word *farmers* is used to designate the class whose business it is to cultivate the soil. We like this better; it smacks of the soil, it implies personal participation in the cares

and labors of planting and harvesting; it is a term implying independence, industry, health. Our Southern patrons, in writing to us, frequently speak of themselves as "farmers," and we are pleased to notice it. It is a source of much gratification to learn through the Southern agricultural press, and through correspondence, of the great zeal and industry manifested by the farmers of that section in improving their lands and developing their immense resources. The journals devoted to agriculture which reach us from the South are wide awake, and we read them attentively. The young men, particularly, are full of zeal and hope, and if there are any improvements in machinery, or farm implements, or fertilizers, by which their interests are likely to be promoted, they seek for them. Soil cultivation is being studied as a science, and cotton will soon be raised so as to afford a larger profit than heretofore. The neglected rice fields of the Carolinas are receiving attention; and if the "heathen Chinee" can be introduced into the rice swamps successfully, this splendid crop will soon attain an importance greater even than in the times prior to the "late little unpleasantness." We wish our Southern friends the most complete success in their agricultural labors, and we are confident they will attain it, in the path they are now pursuing.

LIME AS A FERTILIZER.

Manures may be classed under three principal heads: first, those which supply some essential element to the plant; second, those which act as mere stimulants; and lastly, those which do not act directly on the plant, but act on substances already in the soil, rendering them more suitable for plant life. Lime belongs to this last class almost entirely, as there are very few soils that do not contain sufficient lime for any direct demands that plants are likely to make on them.

In order that a plant may feed on the inorganic matter in the soil, or, indeed, on any matter, it must be brought into a soluble state. Plants feed only on liquids and gases; they have no power of assimilating solid food.

The inorganic portions of plants are built up chiefly of potash, soda, lime, magnesia, combined with silicic, sulphuric, phosphoric, and hydrochloric acids, as well as with many organic acids. The carbonates, so generally found in the ashes of plants, rarely exist in the plants themselves, being mostly formed from salts of organic acids during the process of burning. A small portion of the above-mentioned bases already exist in the soil in a soluble state, but are much more abundant in the insoluble condition.

If, however, we add caustic lime to a soil, it renders these insoluble substances soluble, and prepares them for the use of the plant.

All soils formed from the decomposition of granite contain an abundance of potassa and silica, the most important elements for the growth of the wheat plants. But these two elements are combined with each other, and with alumina, in the form of feldspar, which is almost perfectly insoluble. Caustic lime breaks up this combination; and accordingly, when the farmer finds that his wheat straw is getting too feeble to support its own weight, he applies lime to the soil, with the immediate effect of stiffening up the straw. Fifty or sixty years ago, the farms in New York, Pennsylvania, and Virginia, had almost run down, and were not considered worth fencing. These were called "old fields;" and such may still be found in abundance through Maryland and Virginia. They had been cropped through consecutive years with the same plants, until they would no longer yield enough to pay for the trouble. In some parts of Pennsylvania lime is abundant, and upon applying it to the worn-out soils the effect was remarkable. Farms that thirty or forty years ago could almost have been had for the asking, are now known as being among the best in the State.

But it is not on the inorganic portion of the soil alone that lime acts. It bears, perhaps, an even more important relation to the organic portion of the soil. In Norway and Sweden, every farmer has to pay a portion of his tax to the government in saltpetre. In order to prepare this, he heaps together old mortar or lime, manure, ashes, and earth, and keeps the heap moist. The lime and the nitrogenous matter of the manure react on each other, and form nitrate and carbonate of lime. Nitrate of lime is decomposed by the carbonate of potassa from the wood ashes, and saltpetre is thus formed. Precisely the same kind of reaction is going on continually in the soil when we apply lime to it; and thus the nitrogen of the decaying vegetable matter is brought into fit condition for the use of plants. For all these uses the more caustic the lime is, the better for the land. A heap of lime that has been long exposed to air and rain is much less valuable than that which is freshly slacked, as it has absorbed carbonic acid from the air. Carbonate of lime is of but little value as a manure, although, when it is finely divided, as when it is in the state of chalk, it may serve to neutralize the vegetable acids that exist in some wet lands. It is undoubtedly better to apply lime directly to the soil than to make a compost of it, with peat, or such substances, for we do not gain enough by the mixing to pay for the expense of the manipulation. We have been frequently asked how much lime should be applied to the acre. This is a very difficult question to answer, unless we know all about the soil to which it is to be applied. What would be an excessive quantity for some lands is too little for others. In some sections, or upon some lands, one hundred bushels to the acre may be applied with beneficial results; in others, fifty or sixty bushels are an abundance, while some lands will not bear more than twenty or thirty.

Lime should never be applied directly in association with manure, as it tends to drive off the ammonia, and thus lower its value. If we wish to apply it to corn or wheat land, it is best, perhaps, to top-dress the sod the year before we intend to plough. The manure may be then applied, and ploughed under in the spring, without much danger of loss, as the lime has been doing its work during the winter.

CANKER WORMS.

We hold firmly to the good old maxim that an ounce of prevention is worth a pound of cure. Sprinkling trees with carbolate of lime, with tobacco water, and the various other agents that have been proposed for the eradication of canker worms are well enough in their way; but the remedy is applied too late, for the real mischief comes from allowing the worms to be hatched. This we can prevent by keeping the insects from ascending the trees in order to deposit their eggs.

We may, to a great extent, prevent the mischief by keeping the ground beneath the trees well stirred, and we know of no way to accomplish this better than to turn into the orchard a few hogs. Give the orchard a good ploughing in the first place towards the latter end of August, and then let the hogs have their own way. They enjoy the work, and make a speedy end of all worms and insects that they find.

But even a good ploughing may do a great deal of good, without the hogs. An orchard came under our notice the present season which was saved in this way. Late last October the ground was ploughed for spring planting, and these trees escaped the pest altogether; while those only a stone's throw from them, on old ground, were entirely deprived of their foliage.

The insect may be prevented from ascending the trunks of trees by nailing a strip of roofing felt around the tree, a foot or two from the ground, and keeping this thoroughly coated during the fall and succeeding spring with printer's ink. Refuse ink can be readily obtained at most printing offices, and a little of it goes a long way. This is much superior to coal-tar, as it does not stiffen so readily in cold weather, and it keeps moist longer when exposed to the air.

FARMERS' CERTIFICATES.

The *Vermont Farmer*, after referring to our article on this subject, published several months ago, adds the following sensible remarks with regard to the *remedy* for the evil: —

"There is a large class of these 'certifiers' that are honest men, and fully believe the statements to which they affix their names. And yet the articles recommended really have not the value, even if they have any value, which those certifying believed that they possessed, and the consequence is a loss to those who put trust in them and their indorsers. In this way not only are fertilizers, seeds, and implements, but quacks and quack medicines, worthless books, and many other things floated on the market, and the people thereby taxed for the support of rogues.

"What is the remedy? We can see no other than a better education for the people. Farmers, with even a very moderate knowledge of chemistry and mechanics, would never be entrapped into recommending valueless manures or machines. If they were even puzzled by specious pretexts and saw some apparent plausibility in the claims of dealers or inventors, they would still have such intelligent doubt as to prevent them from making fools of themselves and misleading their neighbors. A little knowledge of botany would prevent them from planting horse beans under the supposition that they were 'coffee,' buying pears 'grafted upon the black ash,' chess as a valuable grass, Hungarian millet for 'Japanese wheat,' and also prevent them from being seduced into puffing such things, either by certificates or through the newspapers.

"Nothing is so expensive as ignorance, and when our people recognize the fact, and are willing to provide the means for a sound and useful education adapted to the times, in all our public schools knaves will not find so many tools ready to their hands, nor so many victims to gull and swindle."

Errata. — In our last number we stated that the respective diameters of Messrs. Cooke and Clark's telescopes were 24 and 25 inches. We should have said 25 and 26 inches.

HINTS FOR THE FARMER.

A Good Cistern. — A writer in *The Plantation* gives the following sensible directions for the construction of a cistern that will keep water both cold and pure: "Excavate in circular form (for economical reasons) to the depth of sixteen feet or more, wall up all round from bottom ten feet; at this point turn an arch for top, leaving a man-hole for the purpose of cleaning, and continue an opening or flue to the surface of the ground. The filter can then be built on the top of the arch, or at any convenient point near it. This filter is also under the surface, and contains, first, a layer of charcoal; second, a layer of gravel; third, a layer of charcoal, pounded fine, not dust; fourth, another layer of gravel; then a layer of sharp sand. A filter constructed in this way will arrest all vegetable and solid matter that may be washed off the roof. Rain water, if caught in this way, then stored sixteen feet deep under ground, with six feet of earth above the cistern, can develop no animal life, because the temperature is below that which brings animal germs to life.

"From sixteen to fifty or sixty feet below the earth's surface may be termed the region of invariable temperature, which is put down at, say, 53°. Now, if rain water in winter at 32° is allowed to enter a cistern at the depth mentioned above, it follows that it will soon become heated to 53°, or equilibrium. Likewise, if summer rains are allowed to enter the same cistern at a temperature of 85°, following the same law of equilibrium, they will soon be cooled to 53°, the temperature of well water. Every observer must have noticed that water may stand undisturbed during the whole summer in wells, without developing animal life, or becoming impure, but if brought to the surface, and exposed to the summer temperature, the organic matter in it soon decomposes, and life develops in it with astonishing rapidity. My attention was called to this matter by the superior coldness and purity of the water of a cistern located in a deep cellar, and investigation convinced me that its superiority was due, not to the shaded position of the cistern, but to the invariable temperature in which the water was stored."

Cheap and Durable Wrought Nails. — Every farmer probably understands the usual method of making cut nails flexible by heating them; but if, instead of allowing them to cool in the open air, they are thrown when red-hot into linseed oil, it will prevent their rusting almost as long as if they were "galvanized." Those who have occasion to use cut nails instead of wrought, should not forget this simple method of preventing rust.

Pickling Green Corn. — This is a much cheaper method of preparing corn for winter use than canning it. When the corn is a little past the tenderest roasting-ear state, pull it; take off one thickness of the husk, tie the rest of the husk down the silk end in a close and tight manner; place the ears in a clean cask or barrel compactly together, and put on brine to cover the same of about two thirds the strength of meat pickle. When ready to use in winter, soak in cold water over night, and if this does not appear sufficient, change the water and freshen still more. Corn prepared in this way is excellent, very much resembling fresh corn from the stalk.

Turnips for Milch Cows. — A recent English writer puts in a strong plea for turnips, accounting them considerably superior to carrots or mangel-wurzels for milch cows. The milk induced by mangels is large in supply, but of poorer quality and not nearly so productive of cream as that resulting from the use of turnips; and the taint given by the former roots is more objectionable and less easy to obviate or overcome to a passable degree. For carrots the only recommendation is the absence of all unpleasant taste in the butter, as the milk is neither so abundant nor so rich as that obtained by turnip feeding.

EXPERIMENTS WITH PLATES OF GALVANIZED IRON.

The following are the results of some careful experiments made with the view of ascertaining the action of Cochituate water upon zinc-covered iron surfaces. The metal used was the plate iron, known in the market as "galvanized iron." The table below gives the weight and size of specimens, the number of hours they were exposed, the loss or gain from the action of the water upon the zinc, and the conditions under which the plates were subjected to water action:

No.	Weight of specimens in grams.	Gain or loss in hours.				Size in millimetres.	Conditions of experiments.
		24	48	72	120		
1	13.3767	0.7	1.4	1.7	1.7	35×61	Surface one half exposed to water.
2	14.5933	.8	.8	.8	3.3	43×50	Changed once in four hours.
3	11.9010	.0	.0	.0	2.0	30×61	Wholly immersed in water
4	17.8210	.3	6.0	8.0	9.5	39×67	Placed in running water.
5	16.0540	0	.0	.0	3.0	40×69	Alternating wet and dry
6	18.3600	1.5	2.5	4.5	8.5	41×65	Immersed in same water as No. 3.

A plate of the metal weighing 10.8480 was subjected to the action of caustic potash to remove the zinc coating. When action was complete, it was found to weigh 9.5590, having lost 1.2890. The percentage of zinc deposited upon the iron was thus found to be 11.89.

This investigation affords some interesting and important results, which cannot fail to attract attention. In the first place it proves that Cochituate water acts promptly and continuously upon zinc-covered iron surfaces. It is shown that the action is more energetic when the metal is partly exposed to air and when the water is changed frequently, and also that in running water the decomposition is most rapid.

The zinc-covered plate, when exposed alternately to the action of water and air did not lose weight during the first three days, and on the fifth it *gained* in weight as is shown in the table. By the action of water and air the insoluble oxide formed adheres to the plate and soon arrests action, and this explains why roofs and other exposed plates of zinc do not rapidly corrode and become worthless.

Specimen No. 3, wholly immersed in water, did not lose weight until the fourth day, when the action commenced with considerable energy, and two milligrams of zinc were dissolved. The specimen No. 6, placed in the same water, gave rise to active oxidation, and it was continued vigorously, so that at the end of the fifth day *eight and a half* milligrams were produced. This result is almost inexplicable, and shows the importance of a more extended knowledge regarding the action of water upon zinc.

The rate at which zinc is oxidized in running Cochituate water gives, for every eight square inches of galvanized iron pipe, 9.5 milligrams in five days. A one-inch pipe, fifty feet long, exposes 1887.5 square inches to the action of the water. This would remove six and nine tenths grains of metallic zinc each day, which corresponds to 8.6 grains of the oxide. It is probable from the results of the investigation that the action continues to increase in energy until the whole coating is removed. If the amount of zinc deposited upon pipes is as large as that found upon the iron plates, it would require two or three years for it to entirely disappear. Waters in their action differ in accordance with their peculiar characteristics, some corroding with great rapidity, others more slowly. *There cannot be a doubt but that the waters of all springs, wells, ponds, and rivers act upon zinc promptly and continuously, and hence the danger of employing the metal for water conduction.* The oxide is insoluble in water, but in pipes it forms a light, flocculent powder, which is almost permanently held in suspension, and easily and readily flows along with the water, and hence becomes mixed with articles of food into which the water enters.

STEAM BOILER EXPLOSIONS.

The amount of positive knowledge we have regarding the nature or cause of steam boiler explosions is certainly no greater than that possessed fifty years ago, and everything pertaining to the matter is at present involved in obscurity and doubt. The rigid and careful investigations made by seemingly competent parties into the dreadful casualties that occur so frequently, do not result in settling controverted points, or even in affording explanations which satisfy any one. This is indeed rather annoying and disappointing, and we may say further that it is humiliating to those who boast much of the progress of science and knowledge in this age.

The recent great catastrophe in New York by which more than two hundred men, women, and children were killed or badly injured, has awakened a wide-spread and deep interest in the subject of boiler explosions, and an immense amount has been written and said upon the subject. We have carefully examined into the circumstances connected with every boiler explosion which has

occurred within our reach during the past quarter of a century; and the numerous explosions of one kind and another which have occurred in our laboratory experience have also been studied with the view of ascertaining the cause and conditions under which they occurred. At the Montreal meeting of the American Association for the Advancement of Science, in 1858, we read a paper upon a remarkable explosion which occurred at a steam saw-mill in Haverhill, Mass., in that year. This paper provoked considerable discussion, in which Professors Henry, Bache, and Peirce participated, and it was singular to notice the wide dissimilarity of views expressed by these eminent gentlemen, regarding the cause of the explosion.

The suddenness with which the disruptive forces operate, and the complete wreck which is made of the steam apparatus and buildings, puzzles every one who is inclined to regard the results as due to the expansive force of steam alone. To account for the awful tearing and crushing effects, it seems to many necessary to suppose that some electrical forces, or explosive gases are concerned in promoting the casualties. Not a few reputable chemists and physicists cling to such ideas, and will admit of no contradiction in discussing the subject.

It is difficult, nay, quite impossible at the present stage of scientific knowledge, to understand how any such agencies can be present to cause, or to aid in causing boiler explosions. The theory so often proposed, that the gases, resulting from water decomposition, do the mischief, is manifestly untenable and unsound. We have no space at command in which to discuss this notion; indeed, it is not advisable or necessary to do so. No theory based upon this idea can be intelligently defended; at least this is the view we take of the matter. As to the electrical forces, and the possibility of their presence in these casualties, there is this to be said, that not a particle of proof can be offered in support of the theory, and it seems equally absurd with the other. Electricity always has been, and we suppose always will be a kind of pack-horse, astride of which any dark problem in science may be placed. We have met with explosions resulting from the accumulation of elastic vapors, as those of ether, chloroform, bisulphide of carbon, etc., and those from fulminating compounds, the gases, and gaseous mixtures, and a great variety of chemical agents which have often placed us in great peril, and from many of which we have not escaped without injury. Two heavy explosions of copper vessels in which was stored carbonic acid gas, have occurred whilst we were engaged in experimenting with the agent, and these we regard as more exactly representing the conditions under which steam boilers explode than any of the others. Boilers acted upon by steam gradually accumulated, and cylinders of metal subjected to pressure by carbonic acid developed under similar circumstances, are placed in conditions quite alike so far as the nature of the mechanical force is concerned. The decomposition of any of the alkaline or earthy carbonates with acids, enables us to develop the gas at will, and we can confine the agents in strong vessels and generate the gas slowly or rapidly, and thus graduate the pressure the same as the engineer controls pressure in his steam boiler. This is done in the ordinary way of manufacturing what is known as "soda water." It is well known, however, that these strong vessels often explode with great violence, and many lives have been lost from this cause. One of the vessels which exploded in our hands, was torn asunder in the middle, and the lower portion was forced through a double floor into the cellar, cutting off beams in its way, and making an orifice nearly four feet in diameter. The report was loud, and the destruction of the surrounding apparatus was well-nigh complete. In these cases we get violent explosive action from excessive gas pressure, and why should we not have a display of similar force from simple steam pressure? In the case of the gas, the supposition that it is aided by electricity or any extraneous suddenly developed agents, is absurd, and it is equally absurd to suppose that any other forces but steam are brought into play when boilers explode. The recent explosion in New York was undoubtedly caused by steam pressure, the force from within acting upon plates of iron probably weakened by having been long subjected to the strain. We are led to believe that the crystalline structure of metals is changed when they are subjected to constant pressure for several consecutive years, and consequently they are weakened and more easily ruptured.

The consideration of this important point requires more space than we have at command, and therefore it will be deferred to our next issue.

ANALYSIS OF LIMESTONE.

In the last American edition of Fresenius's "Quantitative Analysis" it is mentioned that small quantities, under half a gram, of lime may be determined by converting it into the oxide and weighing it as such. We have used this method constantly for some years, and have never restricted ourselves as to the amount taken. In fifteen minutes with a good blast-lamp we can drive the carbonic acid completely from one or two grams of any specimen of limestone or dolomite that we have ever met with. We have found the following method perfectly satisfactory for analysis of limestones and dolomites, free from pyrites.

For H_2O. Grind the mineral to a fine powder and dry it at 100° C. until it ceases to lose weight. A weighed portion is then heated to incipient redness and again weighed; the difference in weight, if any, gives the combined water.

The same portion is again heated for about fifteen minutes over a Bunsen gas blast-lamp. It is then weighed and ignited again for about five minutes. If at the end of the second ignition the weight does not differ more than a few tenths of a milligram, it may be regarded as constant. The loss of weight, less the amount of water, will be the weight of CO_2.

The residue is then dissolved in HCl, evaporated to dryness, moistened with HCl and again evaporated to dryness, in order to render the silica insoluble. It is then treated with dilute HCl, and the insoluble silica collected on a filter and weighed in the usual manner.

In the filtrate determine the Fe_2O_3 by precipitation with ammonia, having previously added a little bromine water to oxidize any ferrous oxide that may be present. If alumina is present, the iron and alumina may both be weighed together. The ignited residue is then treated by Deville's method as modified by Cooke.

In the filtrate from the iron determine th lime by precipitation with oxalate of ammoni The oxalate of lime is ignited over the blas lamp until it ceases to lose weight; from its fine divided state it is much more readily convert into the oxide than the native carbonate.

The magnesia is determined by precipitatic with hydro-disodic phosphate in the usual way.

We think that any one who has tried the co version of calcic carbonate into the oxide w never be persuaded to go back to the old meth of determination as carbonate.

In case the limestone contains organic matte the above method will have to be slightly mod fied, by determining the carbonic acid with son of the many forms of apparatus devised for th purpose. The difference between the amount acid found in this way and the loss of weig after having driven off the water, will give ve closely the amount of organic matter presen If P_2O_5 is present, it may be determined by th molybdate of ammonia method. We have ol tained very good results when the quantity w above half of one per cent. with Munroe's metho

OPPOSITION TO NEW INVENTIONS.

In an article on "The Spread of Inventions which appeared in the Journal for Augus 1870, and portions of which are still going th rounds of the press uncredited (we have see them within a fortnight in papers from Georg and from California), we gave some examples o the slowness with which valuable inventior travel from one country to another, and of th popular clamor that is often raised against the Among these examples were such every-da household comforts as chimneys, and table-fork both of which were at first ridiculed and decrie as marks of luxury or affectation; and even suc a plain, practical contrivance as the saw-mill, th introduction of which into England was ke back a full century by the opposition it encou tered.

The instances we mentioned are but few o many that might be drawn from the history o invention in modern times. Everybody know that Fust (or Faust, as his name is commonl given), one of the trio who invented printin was charged with being in league with the devi and that he and his coadjutors found it no eas task to overcome popular prejudice against the new way of making books. And it was no until three centuries later that the art of printin had become established in every country of Eu rope — if Turkey, where the first printing-pres was set up less than a hundred and fifty yea ago, is to be counted as a country of Europ and not rather as a part of Asia, overlapping th European limits. From 1726 to 1740, that firs press at Constantinople sent out only twenty three volumes. It was then stopped; and it wa forty years before another press was established at Scutari. After issuing about forty volume in some twenty-five years, that also was stopped in 1807, and it was not until 1820 that it re sumed operations.

The ribbon-loom was invented in the sixteent century, and on the ground that it deprived man workmen of bread, it was prohibited in Holland in Germany, in the Papal dominions, and in othe parts of Europe. At Hamburg, a loom was pub licly burned by order of the authorities. The stocking-loom was equally unlucky. In England

it was commended to the patronage of Queen Elizabeth, but her influence does not appear to have been exerted in behalf of the invention, if, indeed, it was not used against it. In France, it was brought into discredit by a contemptible trick of its enemies. A pair of silk stockings had been woven for presentation to Louis XIV., but the parties who supplied hosiery to the court caused several of the loops of the stockings to be cut, and the work of the new machine was condemned as imperfect.

The glazing of earthenware is effected, as is well known, by throwing common salt into the oven at a certain stage of the baking. This process was introduced into England, in 1690, by two brothers, who came to Staffordshire from Nuremberg. They kept it carefully secret, but their success excited the jealousy of rival manufacturers, and the persecution to which they were subjected soon compelled them to give up their works.

It is a familiar story that Galileo was led to invent the pendulum from watching the slow and measured swing of a large chandelier in the cathedral at Pisa. It may not be so generally known that so late as the end of the seventeenth century, when it was proposed as a standard of measure in England, it was ridiculed, and the nickname of "swing-swang" applied to it.

The spinning-jenny was invented by James Hargreaves, a poor weaver of Blackburn, England. He kept it a secret, and used it solely for his own work, but the matter leaked out through the indiscretion of his wife Jenny; and the result was that the weavers of Blackburn broke into his house, destroyed the machine, and drove the luckless inventor from the town. His is but a single instance out of scores of a similar character, connected with the introduction of labor-saving machinery in the manufacture of woven fabrics.

The nineteenth century can furnish more than one illustration of our subject. The world is slow to unlearn its old habit of stoning the prophets that come with the good tidings of a fresh blessing for the human race. The ignorance of the multitude, who imagine some mysterious danger in every marked departure from the ways of their fathers, and the selfishness of the few, who think more of the temporary loss their own craft may suffer than of the lasting gain the rest of the world will receive from the new device, are alike enlisted in warfare against it. When it was first proposed to light London with gas, the imaginary perils of the undertaking, in the eyes of the good people of that day, were not unlike the real ones that attend the use of bad kerosene in our own generation. If the pipes laid for the conveyance of the invisible vapor had been filled with gunpowder, the risk of being blown up could not have appeared more serious, nor could the outcry against the scheme have been louder. But we presume that it was not a great while before the frightened cockneys walked their native streets without fear of artificial earthquakes, and lit their gas-burners as fearlessly as if they had been the candles of the "good old times." "How use doth breed a habit in a man," even if he be ever so conservative!

☞ "Book Notices" and "Answers to Correspondents" have been crowded out of this number.

EDITORIAL NOTES.

A Railway Incident in England. — There are many excellent points in the management of English railways, but in some respects they are decidedly behind the times, looked at from a Yankee point of view. It is but very recently that English trains have been furnished with any means by which passengers could communicate with the conductor or the engineer in an emergency; and even now apparatus of the kind is the exception to the rule. So far as we know, the chief objection made to its general adoption has been that the exuberent vivacity of the British temperament would lead to playing tricks with the cords and bells; and so lest some sportive cockney should attempt a practical joke, the lives of thousands have been daily endangered. An English journal before us furnishes an illustration in point. "Last Wednesday," it says, "an excursion was organized in order to give a certain number of school children a trip from Selby to York and back. On the return journey, when about seven miles from York, by some means as yet unexplained, about 100 yards of signal wire got entangled with the train, which was then running at a high speed. This wire was lashed about in all directions at the rear of the train; it threw into the air quantities of gravel and stones, tore up the posts first on one side then on the other. If the train had passed a station or houses, the last carriages would probably have been jerked off the line, and any persons happening to be standing on the embankment, or at a crossing, might have been killed. The local papers state that the passengers, being alarmed at the unusual noise, looked out, and, perceiving something was wrong, contrived to secure the attention of the guard, whether by thrusting themselves or one of the school children well out of the window does not appear; but 'the guard failed to attract the attention of the engine driver.' So the train continued ploughing up the gravel, and lashing the posts with its wire whip, until by a happy chance the wire was disentangled and left behind."

Newspaper Science. — We find the following in a leading article in one of our exchanges: "We have no means of ascertaining the distance of the fixed stars. When, therefore, they are said to be in the Zodiac, it is merely implied that they are situated in that direction, and that they shine upon us through that portion of the heavens which we call the Zodiac. Whether the apparent difference of the size and brilliancy of the stars proceeds from various degrees of remoteness or of dimension, is a point which astronomers are not able to ascertain. Considering them as suns, we know no reason why they should not vary in size, as well as the planets belonging to them."

The writer does not appear to be aware that the distances of quite a number of the fixed stars have been pretty accurately measured, and that these measurements prove that some of the brightest stars are much farther off than others that shine with fainter light. Sirius, for example, the most brilliant of the heavenly host, is unquestionably more distant than the star known as 61 *Cygni*, which is barely visible to the unaided eye. The latter, by the way, as most of our readers do not need to be informed, was the first of the fixed stars whose distance was ascertained. A comparison of the brightness of stars whose distance is known with the light given by the sun proves, not only that these remote orbs "vary in size," but that some of them are vastly larger than the one which forms the centre of our own system. These facts, now familiar to schoolboys, ought surely to be known by any one who ventures to write newspaper articles on astronomical topics.

Here is another little paragraph which we cut from a paper which is rarely at fault on scientific subjects. "The *Seneca Falls Reveille* says: 'A son of Isaac Bishop, living near Ovid, about thirty years of age, has whittled out a wheel that will run until worn out. A rather singular coincidence, that at about the same date with the above, a man living near Bearytown has also produced a self-running machine. It may be held fast by the hand, and upon releasing the hold will start off itself and gradually accelerate until it gains its maximum rate of speed. It is thought by those who have seen it, that it can be applied to an almost endless variety of uses, and is consequently worth millions of dollars to the inventor.'"

Though it has been shown, again and again, that "perpetual motion" is a mechanical impossibility, since no machine can create power, or even apply power without losing or wasting more or less of it, it is hard to make some people believe it; and paragraphs like the above are continually appearing in the papers. It is a noteworthy fact, however, that these wonderful inventions which are going to do so much work without any motive power, and make so much money for their originators, are never heard of afterwards.

Galvanized Iron Pipes. — Those interested in furnishing these dangerous water-pipes appear to be zealously engaged in defending their wares in the newspapers. They have some worthy coadjutors and defenders among the doctors, and they claim to have a friend in no less a person than the Secretary of the Massachusetts State Board of Health. Dr. Derby is too respectable a gentleman to be found in such company, and for the sake of his reputation we hope he will explain himself before long. The text from which the newspaper gentlemen preach is that supplied by Dr. Winsor of Winchendon, whose *luminous*, *scientific*, and *exhaustive* "report" we have several times commented upon in the Journal. No facts, no experiments, the results of no investigations are presented by the doctors who prepare the newspaper articles in support of the pipes. They supply none because they have none to give. These men are not chemists, and in no proper sense are they physicians. It is to be expected that men engaged in a profitable manufacture will attempt to defend their interests; there is for them some apology, some excuse, but for the men who call themselves physicians, and presume to act as advisers upon sanitary matters, none whatever. They do not rise to an equal level of respectability with the quacks who advertise nostrums in the same newspapers in which appear their communications.

A Pleasant Affair. — The grand banquet given in July by the shoe manufacturers of Haverhill, Mass., to the trade throughout the country, was indeed a very pleasant and enjoyable affair. The tables were spread upon the shore of the lovely Kenosa lake, and a party numbering seven hundred assembled about them, and a more social, happy gathering has seldom been seen. There were representatives from nearly all the Southern and Western cities: from Charleston, Memphis, New Orleans, Savannah, Mobile, etc., from St. Louis, Chicago, Cincinnati, and all prominent points in all the States. Business matters were ignored for the time, and the day was devoted to kindly greetings, and social intercourse. The party represented patriotism, influence, intelligence, wealth, and we could not help feeling as we surveyed the company, that if the political affairs of our country could be placed in the hands of such business men for a single year, nearly all the sectional prejudices and animosities created and fostered by miserable politicians would be done away with. It is a pity business men cannot have a larger share in the management of our national affairs.

Prizes for Chemists. — The "Prussian Association for the Promotion of Industry," at Berlin, has offered several valuable premiums for certain *desiderata* in practical science. The gold medal of the association, or the value thereof in money, and in

addition thereto a sum of $750, will be given for a thoroughly reliable and ready method of determining the quantity as well as the quality of the various compounds met with in commercial aniline (aniline oil as it is also termed), and the influence which these compounds exercise upon the manufacture as well as upon the yield of fuchsine; it being also desired that the author should explain under what conditions aniline yields the largest quantity of coloring matter. The silver medal, or money value thereof, and a sum of $225, will be given for the preparation of an opaque red enamel on gold, silver, copper, or bronze. A donation of $185 will be given to the author of a concise and critical work upon the composition of cements in relation to the wants of industry. The silver medal, or the money value thereof, and in addition thereto a sum of $112, will be given to the author of an exhaustive essay on the industrial manufacture, mode of formation, and chemical constitution of coralline (also known as aurine, rosolic acid, and peonine), and on the blue pigment, azuline, derived from it. The silver medal, or its value in money, and, moreover, $375, will be given to the inventor of a yellow-colored solder which possesses the qualities and properties of the ordinary tinmen's solder. The aim of this solder should be to join brass, or similar alloys, in such a manner as to hide the joints from being visible by the different color of the solder.

ATOMS.

CHICAGO has just completed, at the expense of three millions of dollars, a unique and useful enterprise, in deepening the canal connecting the "Chicago River" with the Illinois, so that, instead of flowing with a sluggish stream into Lake Michigan, it runs the other way, through the canal to the Illinois, with a current strong enough to sweep away the filth that used to accumulate in its waters, making large portions of the city almost uninhabitable in summer. — A train on the Pennsylvania Railroad lately made the run of 132 miles from Altoona to Harrisburg, in two hours and fifty minutes, or at the rate of nearly fifty miles an hour. — Earthquakes are unusually frequent this year in all parts of the world, and some one suggests that "Mother Earth," instead of being called *terra firma*, is in danger of becoming known as *infirma*. — In painting the inside of wooden pails, no lead pigment should be used (as serious cases of poisoning have resulted from the contamination of the water by such pigments) but either whiting or gypsum, if a white color is insisted upon, or ochre, if the best material is desired, without regard to color. — The use of torpedoes for increasing the flow from oil-wells has been patented; the process consisting in sinking to the bottom of the well a water-tight flask, filled with explosive material and ignited by means of electricity. — A typographical error may sometimes lead to serious consequences, as in the case of the Bordeaux editor, who was arrested for stating in his paper that "some of the streets of the city have not yet been defiled by the German troops," and who was released only upon making it clear that he had written *fouillés* (searched) instead of *souillés* (defiled). — Fifteen thousand young shad from the Hudson have been "transplanted" to the upper waters of the Sacramento in California, where they appear to be doing very well. — It is rumored that the Duke of Sutherland, in connection with two other wealthy men, is about to buy the Suez Canal for six million pounds sterling, a little more than a quarter of its original cost. — More than half a million sewing machines were made in the United States last year. — It is stated on good authority that more oranges are exported from Mobile than from Messina. — "Ashberrium," a substitute for Britannia metal, invented by Ashberry, of Manchester, consists of 80 parts tin, 14 of antimony, 2 of copper, 2 of nickel, one of aluminium, and one of zinc. — Gum tragacanth mucilage can be prepared much more quickly and of a more uniform consistency by first rubbing up the powdered gum with a little glycerine before the water is added; as in this way the formation of lumps is entirely avoided. — The French and Austrian goverments have begun to raise sponges artificially; the former on the shores of the Mediterranean, and the latter on the coast of Dalmatia, and the cultivation is said to be perfectly successful and very profitable. — A soda lake has been discovered near the Union Pacific Railroad, several miles in circumference, and capable of supplying sixty-five thousand tons of soda annually. — Chloride of tin is much used for the purification of syrup, but unless prepared with great care it is liable to be contaminated with the lead which is almost always present in commercial tin, and lead poisoning may be the result. — Road steamers have been introduced into Brazil, and they appear to be growing in favor wherever they have become known. — The *gamins* of Paris have been doing a lively business in the sale of the teeth of dead Communists, having disposed of five thousand of Dombrowski's dentals at twenty francs apiece; but the market for Cluseret's was spoiled when it was discovered that the report of his death was false. — Tincture of guaiacum, half an ounce, and essence of gualtheria, one drachm, added to one pint of cod-liver oil, completely cover the taste of the latter. John Bull is always interested in questions of genealogy; and that may explain the fact that, since the publication of Darwin's "Descent of Man," there has been a marked increase in the number of visitors to the monkey-house of the Zoölogical Gardens in Regent's Park, London. — The oleander, so popular as a house and garden plant, is extremely poisonous; nearly fatal results having followed the eating of a few buds or leaves. — Despatches have been sent direct, without any re-transmission, between London and Bombay, a distance of six thousand miles by the Indo-European line of telegraph. — A saw-mill owner, at the celebration of his wooden wedding the other day, was presented by his workmen with ten thousand feet of lumber, while a neighbor contributed thirteen large poplar logs. — — The immense business done by some of the leading English railways may be inferred from the number of locomotives employed by them; the London and Northwestern having 1,527, the Great Western 867, the North Eastern 865, the Midland 683, the Caledonian 523, and seven others more than 200 each.

Medicine.

REMEDY FOR POISON BY IVY (RHUS TOXICODENDRON). — I send the following, which I have used for more than twenty-five years with great satisfaction. The tormenting burning pain is relieved instantaneously; and the worst cases are cured in one or two days: —

Bruise, slightly, a handful of White Ash leaves (*Fraxinus acuminata*); add new milk enough to cover; simmer ten minutes, and apply, *as hot as can be borne,* three times a day.

J. D. STEWART, M. D.

COILA, N. Y.

A CASE OF ZINC POISONING.

ON the last Monday of June, 1870, I was called to see Mrs. A. E. F. of this town, twenty-eight years of age, of full habit, and until within two or three weeks, of perfect physical antecedents. Since that time she had suffered from a variety of anomalous sensations which had increased in severity until this date. I will here transcribe her language, expressive of her feelings and condition: "I have pain in my head, feel drowsy most of the time, am sick at stomach, and have a dreadful sensation in my stomach; have to keep expectorating all the time, and the mucus has a disagreeable metallic taste; my limbs ache, I have pains in the knee and ankle joints, my right arm pains me and I cannot control my lower limbs nor my right arm. I have occasional diarrhœa, — no appetite, and when I lie down I am numb all over. I fear apoplexy." She had a peculiarly cadaverous, pinched, unnatural expression of face, a slow pulse, easily compressed under the finger, a moist surface, a dirty, moist tongue. Scanty urine, color not unnatural; and she was raising a large amount of mucus of a milky color. With this train of symptoms, singularly grouped, I came to the conclusion that she was suffering from narcotic or mineral poison, and at once commenced investigating the sanitary condition of the family. My attention was directed to the water-supply, with the following results: During the month of April or early in May a galvanized submerged pump was placed in the well from which all the water used on the premises was drawn, and in the absence of any other visible cause for these strange, incomprehensible phenomena, zinc was suspected. The next morning the pump was removed, and its condition inspected. The zinc coating over a portion of the surface was entirely removed, and over the remainder was thoroughly corroded, so as to be easily removed with the finger, and after drying deposited a fine white powder which I considered carbonate of zinc. Mrs. F—— continued in critical condition for several days. I was enabled, by active, efficient means, to improve the heart's action speedily, but the nausea and distress at stomach and glandular mucous secretion were obstinate in yielding to means administered; the power to use and control the lower extremities continued to embarrass her exceedingly for six weeks. On the 20th of August she was able to be removed to the seashore, and there she recuperated rapidly. She returned early in September, very much improved, though she still had some pain in joints of knees and ankles, and to this day her right arm gives her annoyance in failing at all times to respond to her demands. I have to apologize to the profession that I did not carefully note, as I should now do, all the developments visible and worthy of record, for I was incredulous somewhat in regard to the alleged danger of galvanized iron in water conduction, having never before seen a case where I could trace any effect from its action, and in short, did not comprehend so fully the situation as a subsequent study of the subject has convinced me its importance demands. I have since treated a case entirely unlike the aforesaid, both so far as the physical condition of the patient, and the effects as manifested thereupon are concerned, which I will report at an early day. The latter case has induced some discussion in the daily and weekly prints in this vicinity, and it is a matter of surprise to me that all the evidence that has been adduced through your columns and elsewhere has failed to so great an extent to impress the profession with the importance of this question.

J. R. BRONSON, M. D.

ATTLEBORO', MASS., *July*, 1871.

CHOLERA, ITS ORIGIN AND TRAVELS.

We make the following abstract from an ar-cle on Asiatic Cholera by J. C. Peters, M. D., the *New York Medical Journal.*

He commences with the statement that every atbreak of the disease beyond the confines of ritish India may be traced back to Hindostan, ther through a continuous chain of human be-gs affected with the disease, or through water ontaminated, or articles stained with their de-cta.

Cholera is endemic in Calcutta, where the eaths by it range from 2,500 to 6,400 in a year. he principal cause of cholera in India is the thy condition of the native towns and villages; ese consist of a mass of huts constructed ithout any plan or arrangement, without roads drains, ill ventilated, and never cleaned. Most the native towns are the abode of misery and th, and are nurseries of sickness and disease. hey abound in green, slimy, stagnant pools, full putrid vegetable and animal matter in a state decomposition, whose bubbling surfaces exhale, nder a tropical sun, noxious gases, poisoning e atmosphere, and spreading around disease d death.

These ponds supply the natives with all their ater for domestic purposes, and are also the ceptacles of their filth. Even the artificial nks are fed with water from the drains that unify over the villages and carry out the sewage the huts.

None of the villages possess a single road rough which the smallest cart can pass to re-ove the filth, which is all thrown out of doors.

From frequent heavy rains which occur from me to time, it is easy to imagine how frequently e tanks containing the supplies of drinking ater must be contaminated with all manner of purities contained in the filthy soil.

Dr. McNamara, whose monograph on cholera the principal source from which Dr. Peters aws his information, mentions one case in hich he had the most positive evidence that esh cholera dejecta had found their way into vessel of drinking water. Nineteen persons par-ok of this water — only once; and five of these neteen healthy men were attacked by cholera ithin seventeen hours. Observation has shown owever that this contaminated water may be wallowed with impunity during the process of gestion, the gastric juice being fatal to the infuso-a contained in it. But if it is taken some hours ter a meal, when the stomach is empty and e reaction alkaline, then the cholera matter will t up its destructive changes in the epithelium the stomach, which action speedily extends to e intestines, so that a robust person may easily d quickly succumb to the disease.

Hence persons with weak digestions, and ose suffering from depression of the nervous rce, whether following fatigue or a debauch, are pecially apt to be attacked. If cholera dejecta e cast upon dry ground and no rain occurs, en a high wind may drive clouds of cholera ıst here and there, which, in a few instances, ay be lodged in the mouths and noses of some ersons and thus give rise to the disease. Chol-a may be also spread by dry dust from clothes cholera patients, but a wide-spread epidemic itburst of the disease can only arise through e drinking water of a place becoming contam-nated with dejecta or other cholera matter.

The cholera, once started on its travels, finds plenty of means of locomotion.

The most powerful causes of its spread are the great religious pilgrimages that are continually taking place in India. Hundreds of thousands of pilgrims annually traverse the roads of India, visiting the various sacred shrines. Many of these, poor, ill fed, and diseased, start on their tedious journeys of 1,500 or 2,000 miles; some drop by the way, others arrive worn and exhausted at their places of destination, there to receive the seeds of cholera, and, returning, scatter them along their route.

Every twelve years the festival of Juggernaut has peculiar sanctity, and draws larger crowds from greater distances; and accordingly we find that these years are marked by the wider spread and greater severity of cholera. One of these festivals occurred in 1817, which was a marked year in cholera annals. 1841, 1853, 1865 were also strongly marked years. The spread of the disease, being better understood, was more fully studied during the attack of 1865. These attacks, or Juggernaut cholera as they are called, are supplemented by one occurring two years afterwards, which takes its rise at the great festival of Hurdwar. The last Hurdwar epidemic occurred in 1867. We may therefore expect another great outbreak in 1877 and 1879. The mouth of the Ganges is another sacred place of the Hindoos. From here the cholera is carried up the stream and communicated to the Mohammedans who are on a pilgrimage to their holy city of Allahabad. They carry it northward into Persia, from whence it extends to the Black Sea and Mediterranean, travelling thus far with bands of pilgrims. When it once comes into the Mediterranean it is then in the track of the commerce of the world, and does not often stop until it has reached Eastern Europe and America. Another great route is through Russia. It was by this route that the cholera of 1831 reached England; from there it was carried by British troops to Canada, from whence it passed to the United States, and finally disappeared in Texas. The cholera sometimes travels over two of these routes simultaneously, and sometimes a small portion of the route is reversed.

It has in many instances been carried by moving armies, destroying more men than fell in battle, and turning a victorious march into a disastrous defeat. This was the case in 1821, at which time a Persian army menaced Bagdad and defeated a Turkish force that was collected for its defence; but a few days after the victory, the Prince Royal of Persia saw his army devastated by the epidemic, and recoiled before this new enemy and carried the disease into the heart of Persia. He lost two thousand soldiers from cholera in one march.

MEDICAL MEMORANDA.

Sesquichloride of Iron and Glycerine in Diphtheria, etc. — Professor Clar, of Vienna, after using pure glycerine with great success in various catarrhal and slight diphtheritic affections, was led to try the addition of sesquichloride of iron in some cases of a more severe type, and the results were very gratifying. He first prescribes a gentle aperient, either in the form of a manna draught or of a few grains of calomel. The latter he considers a powerful antiphlogistic remedy, and of great value when properly used. At the same time cold compresses or cloths are applied to the neck or head, or even to the chest, with cold or iced water as drink. He then commences the use of the iron-glycerine, which consists of two ounces of pure glycerine and twenty drops of the liquor ferri sesquichloridi. Of this mixture half a teaspoonful is given every half hour throughout the day and night. As soon as the symptoms appear to be mitigated, the dose is diminished to a teaspoonful every second hour; and in the intermediate period, with the object of dissolving the exudate, a mixture of two ounces of glycerine and twenty grains of borax is similarly given by a teaspoonful at a time. The iron-glycerine is progressively given at longer intervals, and is gradually replaced by the borax-glycerine.

Aqueous Solvent for Sulphur. — To facilitate the use of sulphur in medicine, many attempts have been made to find an aqueous solvent for the substance, but without success. Dr. Pole, however, now announces that if flowers of sulphur, previously well washed and dried at 212° F., are mixed with an aqueous solution of pure carbonate of soda and the whole digested at 212° for 10 hours, considerable sulphur will be taken up. Linseed-oil is another solvent for sulphur, the amount dissolved increasing with the temperature.

Therapeutic Value of Glycerine. — Dr. Fanto (*Wiener Medicinische Zeitung*) remarks that leading dermatologists are coming to use glycerine, locally applied, as a substitute for many internal remedies that have been extensively employed in cutaneous affections. Glycerine has proved especially valuable in cases of abnormal secretion of sebaceous substances. This is caused by disease of the sebaceous glands, and has its seat, not, as was formerly supposed, in the subcutaneous connective tissue, but in the corium itself. Sometimes the complaint takes the form of a hypersecretion from these glands. This occurs for the most part in infancy, and is known as *seborrhœa*. It is most commonly seen on the scalp, on the face near the ear muscles, and, more rarely, on the extremities. In such cases glycerine acts excellently in softening the hardened masses of sebum on the surface of the skin, and in diminishing the irritation of the organs affected. In conjunction with borax, zinc, and acetate of lead, it also diminishes the amount of secretion. In many instances the treatment must be continued for a considerable time, in order to effect a cure.

Glycerine is equally useful in cases where there is a diminution of the sebaceous secretion, which may lead to pityriasis. In this harsh state of the skin, the softness and natural elasticity may be restored by rubbing glycerine into it. None but a perfectly pure article should be used.

A Refreshing Beverage. — Dr. Waller Lewis, in describing the precautions against cholera adopted at the General Post Office, in London, says: "The men employed in sorting letters and newspapers suffer much from thirst, especially in the hot weather, and consequently drink much water while engaged in their duties. Although the Post Office is supplied with excellent water, much diarrhœa was, nevertheless, the result of this practice. To remedy this the officers, clerks, and men of all classes have of late been supplied from the medical department with a most agreeable drink, which not only assuages the thirst, but has, moreover, strong antiseptic and anti-diarrhœa properties. It is called orangeade, and is thus composed: Take of dilute sulphuric acid, concentrated infusion of orange peel, each twelve drachms; syrup of orange peel, five fluid ounces. This quantity is added to two imperial gallons of water. A large wineglassful is taken for a draught, mixed with more or less water according to taste. The officers drank this with pleasure. It is being consumed in large quantities daily, and I am convinced it will be the means of warding off a great deal of sickness."

The Spread of Scarlatina. — Dr. Johnson, Professor of Medicine in King's College remarks

(*British Medical Journal*) that the spread of Scarlatina is in a vast number of instances the result of gross, culpable, and even criminal negligence. If a patient recovering from scarlatina should proceed to the seaside, it is his duty to inform the proprietor of his lodgings of the case, or the next occupants may take the disease should no disinfecting process be adopted. Infection frequently proceeds from sending the clothes of patients to the laundress without due warning. Dr. Johnson mentions the case of a child suffering from scarlatina, whose sister had died of the same disease a few days before. The father was a tailor, and his workshop opened into the room occupied by the sick child. This affords an illustration of the way in which new clothes may become infected. Medical attendants should be careful to avoid conveying the disease to others; washing or disinfecting the hands after touching a patient, and driving or walking in the open air, are obvious precautions. Dr. Johnson mentions a curious instance of the spread of scarlatina. A child was on a visit to a friend in the country, and died of scarlatina. More than a year afterwards another child came to the same house, took scarlatina, and died. In seeking for a source of infection, it was ascertained that a doll which had been nursed by the first child in her illness, and which had been put by in a drawer, had been taken out and given to the second child to play with some days before she became ill. The suspicion seemed confirmed by the fact that in the interval between the deaths of the two children, some older children who had visited the house and had not touched the doll, remained well.

SEASHORE RISKS IN ENGLAND. — *Apropos* of one of the causes of contagion mentioned in the preceding note, the *Pall Mall Gazette* remarks: "At this season of the year the courage of English parents is severely tried, but is seldom found wanting. It needs no small strength of nerve, even on the part of a bachelor, to face the imminent perils of seaside lodging-houses; but the man who ventures to a watering-place with his wife and a family of young children, and takes apartments without knowing who has occupied them before him, exhibits an amount of pluck which is highly to be commended. He knows that small-pox patients and scarlet-fever patients are generally sent to the seaside to recover their strength; he knows that school girls and boys, if attacked with fever, are immediately despatched to private lodgings; he knows that the hospitality, or the necessity, of lodging-house keepers prevents them from asking inconvenient questions, and yet he encounters the risk manfully, nor does his wife exhibit one sign of trepidation. The truth is, the danger is so common that paterfamilias must either stay at home altogether or shut his eyes to it."

CHLORAL WITH COD-LIVER OIL. — An Italian medical journal recommends the addition of chloral hydrate to cod-liver oil. It renders it much less nauseous, and prevents the night-sweats of the phthisical patient, induces sleep, and creates appetite. The pure chloral-hydrate crystals may be added to cod-liver oil in the proportion of ten grains of the former to one hundred and ninety of the latter.

USEFUL FORMULÆ.

COURT PLASTER. — Soak brushed isinglass in a little warm water for twenty-four hours; then evaporate nearly all the water by a gentle heat, dissolve the residue in a little proof spirits of wine, and strain the whole through a piece of open linen. The strained mass should be a stiff jelly when cool. Now, extend a piece of silk on a wooden frame, and fix it tight with tacks and packthread. Melt the jelly, and apply it to the silk thinly and evenly with a hair brush. A second coating must be applied when the first has dried. When both are dry, cover the whole surface with two or three coatings of Balsam of Peru, applied in the same way. Plaster thus made is very pliable, and never breaks.

TO PRESERVE THE OILS OF ORANGE AND LEMON. — C. Fruh, in the *American Journal of Pharmacy*, recommends adding to every pound of oil 1 oz. of pure alcohol, which having been thoroughly mixed with the oil, there is added to it 1 oz. of water, which again withdraws the alcohol from the oil, and collects at the bottom of the bottle as dilute alcohol. The *rationale* of this process appears to be that the alcohol, by removing foreign resinous and other matters present in the oil, retards the oxidation of the oil by the atmosphere.

HÆMASTATIC COTTON. — This is prepared by Dr. Ehrle, by first digesting the raw material in caustic soda, and afterwards saturating with chloride of iron. It has been thoroughly tried in the hospitals of Europe during the last six months, and is everywhere highly commended. It is applied in the same way as lint, and as it absorbs water, close bottles or packages must be employed for preserving it. It would be a good article to have on hand in every household.

GLYCERINE LYMPH. — In Prussia regular revaccination is very generally practised, the law making the precaution obligatory on every person, and the authorities conscientiously watching over its performance. As a natural result cases of small-pox are very rare. It has, however, been objected, there as here, that lymph is scarce. To make the most of such lymph as there is, government has tried its application mixed with glycerine, and the result has been so successful as to lead to a public recommendation of the mixture to official vaccinating surgeons. The manner in which the glycerine lymph is prepared is thus described by the *Reichsanzeiger:* The pustules of a healthy vaccinated person are opened with a needle, and the effluent matter carefully removed by means of a lancet, the same instrument being gently applied to assist the efflux. The lymph is then best placed in the hollow of a watch glass, and there mixed with twice its quantity of chemically pure glycerine and as much distilled water. The liquids are thoroughly well mixed with a paint brush. The mixture may be preserved for use in capillary tubes or small medicine glasses. The lymph thus procured is considered equal in effect to pure lymph; care must, however, be taken to shake it before use. As the same quantity that now suffices for one is thus made to suffice for five, the discovery ought to be extremely useful in crowded cities.

TREATMENT OF INTERMITTENT FEVER BY CARBOLIC ACID.

Translated by Dr. H. TUCK, from *Wien. Med. Presse*, March 19, 1871.

DR. TREULICH reports eight cases of intermittent fever promptly cured by carbolic acid. His formula is: —

℞.	Acidi carbolici	gr. iij.
	Inf. gent.	℥v.
	Syr. simpl.	℥i.
M.	Dose, ʒi. ter die.	

His article closes thus: —

1. Carbolic acid is an admirable remedy for intermittent fever, even for obstinate cases which have resisted quinine.

2. Its action is speedy and certain, and it requires such a small amount that it cannot possibly have any injurious effect on the system.

3. The average amount required was four and one eighth grains.

4. It costs only one thirty-fifth of what quinine does, and so is to be preferred for the poor.

5. This successful use of carbolic acid proves that the action of quinine in intermittent fever is antiparasitic.

6. It also favors the opinion that intermittent fever is the result of a blood poison. — *Boston Medical and Surgical Journal.*

APPROVED COSMETICS.

ALMOND BALLS. —.

Take Spermaceti	2 ounces
White wax (pure)	4 "
Oil of almonds	½ pint.

Melt them together in an earthenware pot by t heat of a water-bath, and when the mixture h cooled a little, add

Essential oil of almonds	1 drachm
Expressed oil of mace	1½ "

Stir the mixture constantly until it begins to co then pour it into slightly warmed moulds, which m be ounce gallipots or egg-cups with smooth bottom This will form hemispherical cakes. They may colored by adding the coloring material while t whole is in a fluid state.

CAMPHOR BALLS. — These are much employ to prevent chapping of the skin and chilblains.

1. Take Spermaceti,	
White wax (pure) of each,	2 ounces.
Almond or Olive oil	½ pint.

Melt them together by a gentle heat, and add

Camphor (cut small)	1 ounce.

Stir until it is dissolved, and then proceed as d rected for "almond balls."

2. Take Clarified suet	1 pound.
Spermaceti	3 ounces.
White wax	2 "
Camphor	1 ounce,

and proceed as before. [Whiteness is a recomme dation to camphor balls, therefore the materi should be as free from color as possible. They ma be perfumed according to fancy.]

CAMPHOR BALSAM. —

1. Take Spermaceti	2 ounces.
Olive oil	½ pint

Dissolve by a gentle heat and add

Camphor (cut small)	1 ounce.

Stir the mixture until nearly cold, and then p into short, wide-mouthed bottles, which should b kept well corked. [Less than the above quanti may be used.]

2. Take Curd soap	1 ounce.
Water	1½ "

Dissolve by heat, and stir in of

Camphor	½ ounce,

previously dissolved in

Olive oil (hot)	3 ounces.

When the whole is thoroughly combined and col add

Oil of origanum.	¼ ounce.
Strongest water of ammonia	½ "
Alcohol	1½ "

and proceed as in number 1. [These are stimulan and anodyne. The first may be used to preven chapping of the skin, to remove chilblains, and t stimulate the growth of the hair. The second i better for frictions in lumbago, rheumatic pain etc.] — *Druggists' Circular.*

OPPOSITION TO VACCINATION IN ENGLAND. — There is still a good deal of feeling against vaccination among the more ignorant classes of the population in Great Britain. Referring to the exhibition at the National Portrait Gallery, a London paper says: "Dr. Jenner, although now placed very high and in an unfavorable light, did not escape frequent observation. A woman pointing to it said to her girls, 'There's the one that's making such a lot of children suffer now from vaccination.'" Whereupon another journal remarks, "Poor Dr. Jenner! with his statue placed in a pond in Kensington Gardens, his picture hung in an unfavorable light, small-pox raging in the metropolis, and the Anti-Vaccination League calling him dreadful names, and casting mud at his memory, his punishment certainly exceeds his offence."

ABOUT 15,000 tuns of ammonia-alum are made annually in England. It is principally consumed in the dye works of Manchester and Bradford.

Boston Journal of Chemistry.

Familiar Science.

IKE SUPERIOR AND THE COPPER MINES.

Lake Superior has always been to us one the wonders of the world. Although it was overed by the Jesuits before Lake Erie or ke Michigan, a great portion of it still remains ost unknown and unexplored.

The white man has merely encroached on its thern and western shores, while the great ntry to the north of it still remains almost *terra incognita* that it was when the Jesuits nded their lonely mission at the entrance to "great sea water," the Gitchee Gumee of the ians. There, at the beautiful Sault de Sainte rie, the mission bell still rings its matins and pers, and the good fathers may still be seen he streets with their long gowns and broad s. The Indians still fish in the rapids for r favorite white fish, holding with the aid of ngle paddle their birch-bark canoes as mo- less as a vessel at anchor, while the current hes and boils around them. But the restless erican has been at work here, and a broad, p canal connects the water of the lake with quiet river below the rapids. This was con- cted by a company who received a land grant n the United States. The tonnage passing ugh this canal is every year becoming heav- for it conveys the products of the vast iron es near Marquette and the copper mines of eenaw Point, and soon the vessels bringing products of the new country opened by the thern Pacific road will begin to pass down.

rom the times of the earliest trappers it has known that there were great deposits of er somewhere around Lake Superior, but the ans, who were always willing enough to sell copper, refused to tell of its whereabouts. it is only within comparatively recent s that the mines have been opened and ed. A trip to these mines is an extremely sant excursion, and one that may combine a t deal of instruction with pleasure. Boats regularly several times a week from Buffalo, ping at Detroit, and going up the lakes as far uluth. The best point, however, for seeing copper business is Houghton, on Portage e, as this is in the centre of the mining re-

ortage Lake is a curious sheet of water. It Keweenaw Point almost in two, and formed ort cut for the Indians who travelled in their -bark canoes. They never ventured far from e, and this inlet saved them many weary s of paddling around the point. But to up for this, they had a "carry" of half at the head of the lake across to the west of the point; and from this the lake takes me. The white man has improved on this by cutting a ship canal through this half of sand, and the largest steamers now pass e once the Indian wearily carried his canoe.

The mines lie on both sides of the lake near Houghton, and extend along the point and westward toward Duluth. Some copper has also been found on the north shore of Lake Superior, but the principal deposits seem to be those of Keweenaw Point. The road from Houghton to Eagle River passes by some of the most interesting of these mines, and among them the Calumet Cliff and Phœnix. This latter mine is somewhat celebrated as being in the same predicament as the man who bought the elephant. A mass of copper was struck some years ago which has been estimated to weigh more than three hundred and fifty tons. It is pure metallic copper, in one single piece, and the question was what to do with it. They could not raise it in a single lump, and it was so compact that they could not blast it. They at last resorted to drilling off piece after piece; but this costs almost as much as the copper is worth. Nearly the whole of the copper mined here is found in the state of metal, and only needs to be smelted to free it from the rock and fit it for use.

The Cliff mine is one of the most interesting, as it penetrates deeper into the earth than any other mine in America. We selected this mine for examination, partly from this reason and partly because it was one of the best supplied with labor-saving appliances in the region.

It is an old saying that when you are in Rome you must do as the Romans do; and when you go into mines you must do as the miners do. So we took off our clothes, and arrayed ourselves in the coarse canvas apparel of the miners. It must be confessed it did not improve the appearance of the party. Each of us was provided with a coarse canvas hat furnished with a pad inside to protect the head from falling fragments of rock, and on the outside with a lump of clay in which to carry our candle. Thus equipped, we commenced our descent. A miner led the way, followed by the party, while another miner closed the procession, in order that there might be no stragglers. The descent for the first seven hundred and fifty feet was comparatively easy, as we went down on the "man engine," which is a curious affair made expressly for conveying the men to and from their work. Two beams of wood, a foot square and seven hundred and fifty feet long, are suspended along side of each other at the distance of about a foot. These beams are so connected with a walking beam that they have a perpendicular motion of ten feet. At distances of ten feet apart are fastened foot boards on which a man can stand, while four or five feet above the foot board is an iron handle which he can grasp. When a man wishes to descend he steps upon the foot board which is at the top of the shaft; he is then lowered ten feet by the motion of the beam, and finds himself opposite a foot board on the other beam, which is then at its highest point; he steps across to that board, which then commences its descent, while the one he has just left is ascending. When the second beam reaches its lowest point the first is again at its highest, and he steps back to another foot board on the first, which is then lowered in its turn. This process is kept up until he has gone down as far as he wishes, when he steps from the beam into a gallery.

Our party all safely accomplished the descent, notwithstanding the loss of a candle or two, which went flaming down into the depths below us. It is a dangerous piece of machinery, however, and a year seldom passes without some fatal accident. The miner makes a misstep in the dark, and is picked up a shapeless mass from the bottom of the shaft. After leaving the "man engine," we walked some distance along a gallery, and then began the real work of the descent; for it was yet nearly five hundred feet, or eighty fathoms, as the captain of the mine expressed it, down to where the men were at work. So we still kept on, down over ladders fastened to the rock, the wooden rounds being sometimes almost worn through, at other times gone altogether, while here and there one would be replaced by an old drill. But at last we found ourselves among the miners. Now and then we would be startled by the dull thud of an explosion, that told us they were blasting in other parts of the mine. We were introduced to the captain of the mine, who kindly offered to explain to us the whole process of mining. The vein of copper-bearing rock varies here in thickness from an inch to about two feet. A shaft is first sunk twelve fathoms deep, which may or may not be on the vein; in the latter case, a horizontal drift is extended until it strikes the vein. Galleries are then driven in both directions along the vein, which are called the *levels*. The mine is now ready for work, or *stoping*, as it is called. This is commenced by working away the top of the level, until it is about ten feet high, the men standing on the fallen rock to do the work. They first break away the rock, and having thus exposed a large surface of the vein, this is taken out. After they have thus got to some distance above the floor of the level, heavy timbers are put across from wall to wall, and on these are laid others lengthwise of the level. They then begin work again, throwing the rock on these timbers, and the copper upon the top of the rock. Openings are left at intervals of every two hundred feet in the timber roofs of the galleries, which are framed around with heavy timbers in the same way that log houses are built; these are called *mills*, and serve to conduct the ore to the level below, from whence it is removed in cars to the main shaft. This process of working obviates the necessity of raising much rock to the surface.

After spending an hour or two watching the miners at their work, we prepared to ascend to daylight once more, after securing specimens of copper as souvenirs of our visit. The copper

looked just as bright and fresh as if it had been burnished. The pieces varied in size from grains of sand to masses that would weigh fifty or sixty pounds.

The ascent was far more tiresome than the descent, and we were glad when we stood once more at the foot of the "man engine." This brought us quickly to the surface. After changing our clothes we proceeded to look after the copper that had already been brought up. We found that it was assorted into two sizes, at this mine, called respectively *barrel* and *stamp* work. The barrel work included pieces that were so large that they could be readily sorted out by hand and packed at once in barrels. The stamp work, or *metal*, was composed of rock and copper so thoroughly intermingled that it was impossible to pick out the copper by hand.

This was taken at once to the *stamps.* These vary in form, from the simple Cornish stamp, — which is a bar of wood or iron furnished at its lower end with a heavy shoe of cast iron, and having near its upper extremity a lug which engages in a tooth placed on a revolving shaft, like that of a trip hammer, — to the highly complicated steam hammer. But they all answer the same object, that is, to reduce the ore and rock to a fine state of division. As fast as it becomes sufficiently fine to pass through the screen in front of the stamps, it is carried off by the stream of water that is constantly flowing through them. The further separation of the ore and copper is now effected, on the principle that if you agitate two substances together in water, the one having the greater specific gravity will sink to the bottom, while the lighter will be carried away by the stream. Many curious and interesting devices have been invented for this separation, but they all depend on this same principle. By continuing this operation long enough, the ore is at last obtained almost entirely free from rock. It is then packed into barrels, and is ready to forward to the smelting works; for although it is now nearly pure copper, it is in too finely divided a state to be of any practical use.

A small amount of native silver is also obtained in these mines, but the most of it finds its way into the pockets of the workmen. Lake Superior copper is the purest that is mined in the world, the only impurity being a trace of silver.

At the smelting works, which we visited at Detroit on our way up the Lakes, all the complicated processes of the Swansea (England) works are dispensed with.

The copper when it comes to the works is already in the metallic state, and only requires to be melted. We found there, in addition to the barrel copper and stamp work, another description of ore known as *mass.* This consisted of huge masses of copper, some of them weighing eight or ten tons. The furnaces used are reverberatory, and resemble those in iron works, except that the top is movable in order to introduce the mass copper. After the copper is melted it is stirred with green wood poles, to reduce the oxide formed during the melting, which would, if allowed to remain, make the copper brittle. It is then dipped out in iron ladles, and run into ingot moulds. Notwithstanding the great excellence of the Lake Superior copper it can only compete with that of foreign manufacture by reason of the excessive duties levied on all imported into the country. The ore can be taken from Chili to Swansea, reduced, and brought to this country, at a lower rate than that for which the mine owners on Lake Superior can afford to work.

ANILINE COLORS.

ANILINE was first discovered in 1826, by Undervorben, who obtained the body while experimenting upon the destructive distillation of indigo. But if this were the only source of aniline, we should still be without the beautiful colors that are now so extensively used. If coal-tar is distilled by steam heat, and all the products that pass over below the temperature of 90° C. are collected, we obtain a colorless mobile liquid, having the odor of coal gas, and known as *benzol.* If this liquid is mixed with strong nitric acid, a violent reaction takes place, and *nitro-benzol* is formed. This is the well-known artificial oil of bitter almonds, which is used as a perfume for soap. When this body is distilled with acetic acid and iron filings, aniline is produced. This is the source of all the aniline found in commerce.

In 1856, Mr. Perkin, while experimenting with aniline in hopes of making quinine, treated it with potassic bichromate. He did not succeed in producing quinine, but he did produce a most beautiful purple dye, which was soon introduced to commerce under the name of *mauve.* A host of imitators at once sought to obtain the color without using potassic bichromate. As the only use of the latter was to oxidize the aniline, they reasoned that they might use any other oxidizing agent. Arsenic, among other substances, was tried, but instead of a purple, the red known as *magenta* was the result. The coloring matter, however, does not contain any arsenic; being a salt of a base called *rosaniline.* Magenta is manufactured on an enormous scale in England, more as a substance from which to obtain other dyes than for direct use in dyeing. A single firm produces twelve tons a week. The quantity of magenta furnished by one hundred pounds of coal, is very small; but this is compensated for by its intense coloring power, since it will color a quantity of wool, nearly equal in weight to the coal. In making magenta on the large scale there are considerable quantities of residual products. These of course have been examined with a view to further profit, and the result has been the discovery of a beautiful orange color called *phosphine.* This is much used to produce scarlet, by first dyeing the silk or wool with magenta, and then passing it through a bath of phosphine.

By treating magenta with aniline, a beautiful blue is obtained. This is insoluble in water, but it is rendered soluble exactly as indigo is, by treating it with sulphuric acid.

Another curious dye formed from aniline is known as *Nicholson's blue.* This is completely decolorized by alkalies, and the color is restored by acids. In dyeing with it, the silk or wool is first immersed in a colorless solution of the dye, and then dipped into dilute sulphuric acid, when the blue is at once developed.

If magenta is heated with iodide of ethyl or methyl, an excess of the iodide being employed, a most beautiful green is the result. If, however, this green is heated sufficiently to drive off the excess of iodide, a violet color is the result; so that it will not do for ladies wearing dresses dyed with this green to sit too near the fire. After all the coloring matter has been extracted from the aniline, a residue remains which has an intense black color and is largely used for making printing ink.

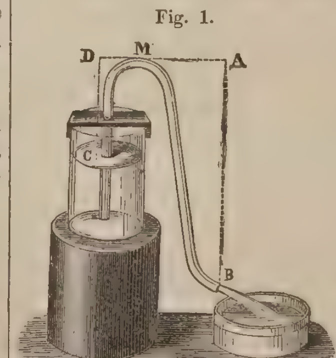
The aniline colors are not so well adapted for cotton and linen goods as for silk and wool. In order to dye the former some mordant is required, and for this purpose albumen is generally used. Very few of the aniline colors when in powder give a person any idea of the color which they will produce when moistened. Magenta, for instance, when dry, is a beautiful green with a bronze-like lustre. It is a pretty experiment to coat a sheet of glass with one of these colors, which is readily done by dissolving in alcohol (Hofmann's violet being one of the best for the purpose) and allowing a film of it to evaporate on the glass. When seen by transmitted light it is of a beautiful violet, but by reflected light it displays a tint rivalling in brilliancy the tail of a peacock. Dirt has been defined as "matter in the wrong place;" this is just what coal-tar was before the discovery of these colors, in the production of which it found its place, and became as valuable as it had formerly been worthless.

THE SIPHON.

THE siphon is as simple as it is useful, but the philosophy of its operation is often misunderstood, even by intelligent people. We have seen references to the instrument in print which showed that the writer had no clear notion of what he was attempting to explain.

If we take a tube bent into the shape of the letter U, with one arm longer than the other, fill it with water, and put the shorter end into a vessel of water, the liquid will flow out through the tube. Why does the water run up hill, as it evidently does in the shorter arm of the tube? It is not enough to say that the pressure of the air on the water in the vessel forces it up to fill the vacuum which the downward flow tends to form in the bend of the tube. The pressure of the air is exerted equally at both ends of the tube, and could not *of itself* make the liquid flow in either direction. If a bent tube with arms of equal length, filled with water, be carefully inverted, the water will not run out, being supported by the upward pressure of the air. But in the case of the siphon (figure 1) the pressure acting at C, and tending to raise the water in the tube, is the atmospheric pressure *less* the weight of the column of water $C\ D$. In like manner, the pressure on the end of the tube at B is the atmospheric pressure *less* the pressure of the column of water $A\ B$. But as this latter column is longer than $C\ D$, the force acting at B is less than the force acting at C, and consequently the water will be driven through the tube by *a force equal to*

Fig. 1.



ifference of these two forces. The greater the ifference of level between *C* and *B*, the faster ill be the flow.

The scientific toy known as *Tantalus's Cup* an application of the siphon. It is a cup, ith a siphon tube passing through the bottom, s shown in Figure 2.

Fig. 2.

f water be poured into e cup, it will rise oth inside and outside e siphon until it has eached the top of the ibe, when it will begin to flow out. If e water runs into the ıp less rapidly than e siphon carries it out, it will sink in the cup ntil the shorter arm no longer dips into the quid and the flow from the siphon ceases. he cup will then fill again as before; and so on.

In many places there are springs which flow t intervals, and which are therefore called *intermittent springs.* In some cases, their action is robably explained by the toy just described. cavity under ground may be gradually filled ith water by springs, and then emptied through n opening which forms a natural siphon. In ome of these springs the flow stops and begins gain several times in an hour.

The siphon affords a convenient means for mptying a vessel without agitating its contents. his is specially desirable when we wish to raw off a liquid without disturbing a sediment t the bottom. It is a very ancient invention, ating back much farther than any form of sucion pump. It was used by the Egyptians at east fifteen hundred years before the Christian ra, as is evident from the paintings found in eir tombs. Heron of Alexandria, who wrote ore than two thousand years ago, describes its se on a large scale for carrying water over a ill in draining lands. The very word *siphon,* hich we get through the Greek, may be of gyptian origin, as Wilkinson has suggested. Whatever its ultimate source, however, there an be no good reason for spelling it *syphon* as even some scientific writers have done), hich is inconsistent with its form in both Greek nd Latin.

COUNT RUMFORD.

Dr. Matthieu Williams, in a recent address efore the Royal Institution of Great Britain, On the Scientific Discoveries of Count Rumord," not only recognizes the distinguished serices which that great man rendered to the cause f science, but in closing takes occasion to enorce in very emphatic language the advantages o be derived from a general diffusion of sound cientific knowledge. He says: —

"The researches of Rumford are especially worhy of general attention, as his subjects literally ome home to all of us, the greater part of his life aving been devoted to studying and applying the hilosophy of common things; he may be in fact egarded above all others as the philosopher of common things, the science of feeding, clothing, warmng, and sheltering mankind having been his chief ursuit. The great characteristic of his whole caeer is that all his practical work was strictly philoophical, and most of his philosophical work was minently and directly practical. He was a great tatesman, a practical soldier, the greatest of practical military reformers, a skilful mechanic and engineer, and a successful philanthropist, besides being a distinguished philosopher. If, therefore, you would make your son a successful soldier, a successful lawyer, a successful statesman, successful in any business whatever, you should give him a sound, practical, scientific education; let him learn how to observe and investigate facts, to generalize them, and from such inductions to deduce sound rules for practical conduct. Modern science affords the best, the highest, and the most useful school of intellectual culture; the great business of the present day is to give to science that decided educational precedence to which it is entitled; and the whole career of Benjamin Thompson, Count Rumford, affords a striking example of the kind of intellectual results we may expect to obtain when sound scientific knowledge and training are afforded to every human being, male and female."

METEORITES.

An attentive and patient survey of the heavens, on any clear night, will not fail to reward the observer with a view of one or more so-called shooting stars, or *meteors,* which suddenly blaze out from one part of the sky and quickly pass across it, not unfrequently leaving a long, luminous train after them, which usually disappears after a few seconds. It has been calculated, on sufficient data, that the number of these bodies which pass through our atmosphere in twenty-four hours, and which would be visible to the unassisted vision, if night prevailed during that time, is not less than seven and a half millions, and that at least four hundred millions would be visible by the assistance of the telescope.

But on many nights the number of these has been so great that they might be compared to snowflakes falling through the air. On the 12th of November, 1833, during the space of three hours, not less than 240,000 were visible from a single point of observation.

In rare instances these bodies reach the earth's surface, where they are called by various names according to the appearance and composition which they exhibit, as meteoric stones, *aerolites;* meteoric iron, *aerosiderites;* the intervening varieties are called *aerosiderolites.*

Those meteoric bodies which reach the earth are probably not on that account different from those which only enter and pass through our atmosphere, or become dissipated in vapor by the passage, but they are only special cases which chance to be pursuing directions favorable to and resulting in final impact.

These bodies are undoubtedly, for the most part, very small, though sometimes weighing several hundred pounds, and they possess a proper motion about the sun precisely as do the planets. The planes of their orbits cutting that of the earth's, they are liable, of course, as a consequence, to be drawn to the earth by its superior attraction, whenever a near approach occurs, or they may possess sufficient velocity to enable them to pursue a modified but uninterrupted course through the upper regions of its atmosphere. In either case it is easy to see that the resistance and friction arising from their enormous velocity must result in raising their temperature to a glowing heat or in dissipating them in vapor. Hence the light and luminous trains which they so frequently leave.

The actual fall of meteorites, when observed, is generally accompanied with loud explosive reports. These find their explanation in the obvious fact that the air must be very greatly compressed in front of them by their rapid flight, and in rushing past them laterally, it quickly falls in and fills the more or less complete vacuum formed in their rear, thus producing the series of reports like musketry or artillery fired in rapid succession.

The reason why so few reach the earth is found in the fact that for the most part they do not exceed a few grains in weight, and hence become entirely dissipated in vapor before reaching us, or in the fact that their velocity and direction enable them to escape the earth's atmosphere before this result is reached.

The bodies which compose the November shower are for the most part exceedingly small, very few weighing more than a pound and most of them only a few grains. It is calculated they begin to burn at a height of seventy-four miles, and are burnt up and disappear at a height of fifty-four miles. Their visible paths are about forty-two miles in length.

Those which are of a sporadic character may be distinguished from those which have a close relation to each other by attending to their frequency, which is much less, and to their directions. Those which constitute the so-called showers occurring in August and November, have been found to be revolving about the sun, in either case in elliptical orbits. The November ones have their aphelion just beyond the orbit of Uranus, and their perihelion on that of the earth, and the plane of their orbit is inclined to that of the earth about seventeen degrees.

The points in the heavens whence these and other meteor showers seem to proceed are called *radiant* points. Upwards of fifty such points have been observed, thus suggesting that there may be upwards of fifty rings of these bodies in constant motion about the sun.

Chemical analysis has shown the presence of oxygen, hydrogen, nitrogen, sulphur, phosphorus, carbon, silicon, iron, nickel, chromium, tin, aluminium, magnesium, calcium, potassium, sodium, cobalt, manganese, copper, titanium, lead, lithium, and strontium.

Careful microscopic study has shown that the matter of which meteorites are composed was at one time in a state of fusion, and that proximately they are made up of small rounded globules, which have accumulated and been more or less fractured by mutual impact, and finally consolidated by the heat produced by their flight through resisting media. — *Bowdoin Scientific Review.*

HOUSEHOLD RECIPES.

To Keep Tomatoes without Canning. — The following is an approved recipe for keeping tomatoes the year round, so that they can hardly be distinguished from those fresh picked from the vines: Dissolve a teacupful of salt in a gallon of water. Pick ripe tomatoes, but not over-ripe, leaving a little of the stem on. They must be kept well covered with the brine.

Fruit Jams. — Boiling fruit for a long time and *skimming it well, without the sugar and without a cover* to the preserving pan, is a very economical and excellent way — economical, because the bulk of the scum rises from the *fruit* and not from the *sugar,* if the latter is good; and boiling it without a *cover* allows the evaporation of all the watery particles, so that the preserves keep firm and well-flavored. The proportions are three-quarters of a pound of sugar to a pound of fruit, — currants, strawberries, raspberries, or gooseberries.

To Keep Fruit. — Beat well together equal measures of honey and spring water in an earthen vessel; put in your apricots, plums, and peaches, freshly gathered; cover closely, and they will keep fresh for a year. When taken out for use, they must be rinsed in cold water.

To Make Good Coffee. — The following is the recipe of Professor Blot, of culinary renown: "Grind the coffee rather fine than otherwise. I think it is usually ground too coarse. I use a coffee pot with a filter. You can get them at any tin store. Mixed coffee is best. I prefer a mixture of Java, Mocha, and Maracaibo. Soft or spring water is best. Proportions, one quart of water to three

ounces of coffee. Of course it can be made stronger or weaker. Four teaspoonfuls make a quart of very good coffee for breakfast.

"In selecting a filter, choose one with a bottom of silvered gauze, instead of perforated tin, as the perforated bottom lets the finely-ground coffee through.

"When the water is boiling hot, put the coffee in the filter, and pour the water over it, and the coffee is made. If the water does not pass through fast enough, set the kettle on the fire again until the water in it boils, when pour it on again. If all the strength is not extracted at the first making, repeat the operation. The coffee may be dark, even black, when strong, but it must be clear. Each kind of coffee must be roasted separately, and it is better to roast it a day or two before using."

The Arts.

"CHROMATIZED GELATINE," AND SOME OF ITS USES.

It has been recently discovered that gelatine, in the presence of a salt of chromium, is rendered insoluble by the chemical action of light. It was at first supposed that the gelatine in this case is partially oxidized, but experiments have shown that it combines with the chromic oxide to form a compound insoluble in water. The fact thus stated might appear to be of little interest except as adding one more item to the interminable list of compounds catalogued by the chemist; but in reality it is a discovery of the highest practical importance. It has already been utilized in the arts in several valuable inventions, and it will doubtless prove useful in other processes yet to be devised.

The most important application of this "chromatized gelatine" thus far is in what is called the "heliotype process." This is virtually a new art of lithography, which promises wholly to supersede the old method. If paper coated with a solution of bichromate of potash and gelatine is exposed to the light, the gelatinous film becomes to all intents and purposes a lithographic stone, from which an indefinite number of copies of a photographic negative may be printed. The heliotype films are prepared by mixing a warm solution of bichromate of potash, gelatine, chrome alum, and water, pouring out the mixture in a pool on a level glass plate, and allowing the film or "skin" to dry. This part of the process was at first conducted in a room lighted only with yellow light; but it was discovered by accident that the film is not sensitive to light until it is *dry*. It is then exposed under a negative, whereby a scarcely visible picture is produced upon the skin, which is afterwards mounted upon a thick zinc plate and soaked in water to get rid of the superfluous bichromate of potash, and render the film insensible to the further action of light. In printing, the surface of the film is treated just like a lithographic stone, for where the light has acted it will take greasy ink, but does not absorb water; where the light has not acted it will absorb water, but refuses the ink; and where the light has partially acted it partly absorbs water and partly refuses the ink.

Some of the earlier prints made by this process were imperfect, but this was found to be due solely to the paper used; and the difficulty has been entirely obviated by the manufacture of a paper suited to the purpose.

This chromatized gelatine is also employed in a new process for rendering woven fabrics water-proof. Cotton and linen that have been soaked in a weak solution of gelatine or glue and bichromate of potash become water-proof on exposure to daylight, without becoming impervious to air. They can be made air-proof by using a solution thick enough to fill the interstices between the threads.

It can also be used for uniting two or more layers of cloth, and at the same time making the double fabric water-proof. The layers are spread with the chromed gelatine solution, put together, and exposed to the light. Leather, paper, and wood may be united in the same way, and rendered impervious to water.

Ordinary glue becomes insoluble in water upon adding a little bichromate of potash to the water with which it is mixed. If the preparation of the glue is conducted in daylight, no special exposure of the articles on which it is used will be necessary.

This insoluble gelatine has been used for making billiard balls, buttons, and a variety of useful and ornamental articles; and, as we have intimated, it is probable that its industrial applications, will be rapidly multiplied. It is certainly a very striking illustration of the important practical results to which the discovery of a single chemical fact may lead.

THE UTILIZATION OF WASTE MATERIAL IN MINING.

Immense heaps of refuse, or "tailings," as they are technically termed, accumulate where mining operations are carried. These contain a good deal of metal, but no way has yet been devised of extracting it economically. We have improved upon the ancients in that respect, and posterity may improve upon us, as is suggested in the following extract from an Australian journal: —

"In the year 4000 or thereabouts, when the Anglo-Australian race shall have been 'played out' on this continent, and our posterity shall have degenerated as the Greeks have done, will the New Zealander of the period, accomplished in arts which are unknown to us, and armed with scientific appliances such as we have never dreamed of, come over to Victoria and extract tons of gold from the tailings in our desolate and deserted gold fields? The question is suggested by what is actually taking place in Attica. About 300 years before the Christian era, the silver mines of Laurium were exhausted and abandoned; but seven years ago a Franco-Italian Company obtained a concession to treat the scoria and other refuse for silver, and their operations have been conducted on so large a scale that a town containing 4,000 inhabitants has sprung up on what was formerly a solitude; a railway has been constructed to the nearest port, and a small steam vessel plies twice a week between Argosteria and the Piræus for the transport of the argentiferous tailings to the roasting furnaces."

MEMORANDA IN THE ARTS.

Silk Spinning in China. — There are three methods of spinning; in two the cocoon is boiled, in the third it is spun raw. For the two first methods, four ounces of soda are put into the water in which a thousand cocoons are boiled, the water is then slightly drained off, the grub extracted, and the cocoons are dried and tied up in bundles. The first method of spinning is by a distaff, and the thread is then called neen-seen. In towns, men of the working-classes, shopmen especially, are seen twisting little distaffs, at every odd and vacant moment, and no small amount of thread is prepared in this way, and woven into cloth, for the spinners' own use. The second method of spinning is by means of a spinning-wheel, and the thread is called kwang-sze. For the third method, peeled rods are stuck in the ground in the form of a polygon, and the thread is wound round this by hand; it is called fang-sze. After the extraction of the grub, it is eaten by the economical and ingenious Chinese of the lower classes, who esteem it a great dainty.

Petroleum Shells. — A correspondent of the *Pall Mall Gazette* states that these explosive projectiles were formed from the ordinary shell, either spherical or cylindro-conical. A light perforated tube, about $\frac{7}{8}$ inch diameter and of a convenient length, filled with loosely packed powder and fitted with an ordinary percussion fuse, was introduced into the shell, which was then filled with petroleum. The powder charge was sufficient to explode the shell and to ignite the petroleum, which was scattered in a fiery rain on all sides around the point struck. The effect of a continuous discharge of such projectiles as these may be well imagined; and it was through their agency, say the Communists, that the Versailles troops, in attempting to gain possession of the Tuileries, set fire to the palace.

Buoyant Mattress. — This is an invention of Mr. J. Hunt, of Providence, R. I., and consists of two elongated sacks or pockets, which are filled with cork, either granulated, cut into shavings, or in large flat pieces, the edges thereof being connected with an apron, so that when the two sacks are folded together upon the apron they will just be covered smoothly thereby, and make a mattress, and when opened they will buoy up a considerable weight placed upon the apron between the cork-filled sacks. At one end is attached a smaller sack, which serves the purpose of a bolster, or, when detached, may be used as a life-preserver. Straps or bands are attached to the surface of the sacks, serving to seize hold of in the water. As a mattress, the sacks are made of any width, so that they will fit into the racks of steamboats or vessels of any kind, and are filled with cork, which is the best known filling on account of its great buoyancy, and, at the same time, is a good filling for a mattress, especially when granulated or cut into shavings. When the mattress is to be used as a life-preserver it is unfolded, and, when in the water, a person or any weight upon the apron within its power of resistance is kept afloat.

New Liquid Fire. — P. Guyot, in the *Comptes Rendus*, gives the following process of making liquid fire. He digests flowers of sulphur in excess with bromine for some time, and then filters the resulting liquid, which analysis shows to be protobromide of sulphur, through asbestos.

This liquid, when brought into contact with liquid ammonia, appears at first inert, but after a few minutes the mixture boils violently and bursts into flame.

Dynamite. — P. Guyot cautions users of dynamite in relation to the boxes and other envelopes containing this compound.

Having in his possession a number of cartridges, made of stout gray paper, he found that these after some time became moist and oily looking, and the pasteboard box in which the cartridges were kept was also found impregnated with a liquid, which on investigation turned out to be nitro-glycerine; dynamite being merely some inert substance saturated with nitro-glycerine.

A small piece of the paper exploded violently when brought into contact with glowing coals, and a like effect was observed when a piece was laid upon an anvil and smartly struck with a hammer.

It was also found that the wood of the boxes in which dynamite cartridges are kept becomes by slow degrees impregnated with nitro-glycerine, and forms a most dangerously explosive material, which

may give rise to serious accidents in warehouses where dynamite is kept.

PRACTICAL RECIPES.

Cheap Sealing-Wax. — The following recipe furnishes a cheap sealing-wax useful for many purposes: Melt together two pounds of common beeswax, six ounces of turpentine, and two ounces of olive oil; add six ounces of red lead, boil a little, and stir until it is almost cold; then cast it into cold water, and make it up into rolls or cakes.

Preserving Anatomical Specimens. — Dr. Ehrhardt says that the simplest means of preserving anatomical and pathological preparations is the use of the following solution: saturated solution of alum, 100 grammes; saltpetre, 2 grammes.

The article to be preserved is immersed in the solution, when it becomes decolorized; but in a few days the color returns, when it is taken out of the solution, and kept in a saturated solution of alum and water only.

Cleaning Fluid. — The *Manufacturers' Review* states that a fluid, called *Liqueur Bernhard*, is sold in Paris to dyers and scourers for removing grease spots, etc., composed of three ounces of beef marrow, one and a half ounces of potash, and a quart of water. It has but a faint odor, but is not applicable to delicate colors on account of the potash in it.

Cheap Lustrous Finish for Woven Fabrics. — The same excellent authority translates the following recipe from a German industrial journal: One pound of wheat starch is made into a paste with six pounds of water, and an ounce of ammonia stirred in. The paste assumes a faint yellow color, and swells up considerably. It is best diluted with five pounds of water, and boiled with constant stirring. After a quarter of an hour's boiling, the excess of ammonia is dispelled, and the yellowish, transparent mass forms a cheap paste as well as a very good finish. Instead of ammonia, half an ounce of caustic soda dissolved in four ounces of water may be used."

An Engineer of Resources. — The *Bethlehem* (Pa.) *Times* says that the "oldest locomotive engineer in the United States is Barney Butz, who now runs an engine on the Lebanon branch of the Reading Railroad. Barney was born in Conyngham, Luzerne County, Pennsylvania, and went on the Beaver Meadow Railroad about the year 1835 or 1836. In 1837 he was running an engine from Parryville to Weatherly, the planes being then in operation. The cars were drawn up the planes by a stationary engine, and were then drawn into the Beaver Meadow mines by a locomotive engine. A good story is told of Barney's readiness in case of an emergency. One day his engine would not make steam well, and he was likely to be overtaken by a passenger train before he could reach the turnout. Seeing a good sized porker beside the track, he jumped from his engine — the train was moving very slow — seized the pig, cut his throat, and stuffed him into the furnace. The fat of the pig was better than kindling wood, and in a very short time Barney had steam up and was out of danger."

Some experiments have been made in the Thames with Holmes's Self-lighting Inextinguishable Signal-lamp, with apparently much success. The lamp is a cylinder of tin, with a conical top; this is filled with a phosphide of calcium. When the lamp is thrown into the water, that fluid, entering the cylinder, effects the decomposition of the phosphide, and phosphoretted hydrogen with phosphorous vapor escapes in great quantities, takes fire spontaneously, and burns with a brilliant light.

England exported more than three million dollars' worth of steam-engines in the first half of 1871.

Agriculture.

A FIELD-DAY AT LAKESIDE.

On the 25th of August we invited about a hundred gentlemen interested in agriculture to visit Lakeside, look over the farm, and partake of our hospitalities. Hon. Simon Brown, editor of that excellent journal, the *New England Farmer*, was one of our guests, and has published the following account of the meeting. Some personal remarks of a complimentary nature we have omitted, and we have also corrected a few slight errors of statement.

PLEASANT GATHERING OF FARMERS.

Many times, in these columns, have we urged the importance of farmers coming together to find change of thought, make new friends, discuss topics relating to their business, and gain strength and wisdom by so doing.

Persons engaged in other avocations do these things, and find profit and encouragement in them. They have no more spare time than has the farmer, and they have fewer conveniences and facilities for social gatherings.

A few days ago Dr. J. R. Nichols, of Haverhill, Mass., invited the Trustees of the Essex County Agricultural Society to visit him at his farm, which is about one mile from the city. A few other gentlemen were also invited, the whole number being about a hundred. Some of the leading New Hampshire farmers were present from Exeter, Hampton, Epping and Hampton Falls. John B. Clarke, Esq., Editor of the *Mirror and Farmer*, Manchester, was also present, and some of the Boston daily papers were represented.

The weather was hot — one of the hottest dog-days; but in the cool shade of the charming oaks on the banks of Kenoza Lake, and fanned by the fresh breeze that came to us after rippling the surface of the sparkling waters, we found the temperature just right for an out-door gathering.

The objects sought in coming together were to know each other more intimately, and to learn of our host something of his new modes of fertilizing and cultivating the soil. The crops of the farm were examined by many persons competent to judge of them, and pronounced good, even for a highly favorable season. The corn was stout and tall, the ears large, and in many instances two perfect ones upon a stalk, and promises a harvest of near one hundred bushels to the acre, besides a large crop of excellent fodder.

The potato crop was carefully examined, and it was judged would yield three hundred bushels to the acre.

Standing in the midst of these crops, the inquiry was made, — "What was the condition of the land before the potatoes were put upon it?" The reply was: "Three years ago it was covered with young oaks. These were pulled out by the roots, the land thoroughly ploughed and pulverized, and last year planted with potatoes. Gypsum and ground bone were applied to the hill, and the crop was a large one. Last spring it was ploughed deeply again, pulverized finely, the same fertilizer applied, the weeds kept down, and here is the result. *They have had no stable manure whatever!*" The potatoes were large, fair, and as good-looking as potatoes could well be. The reader ought to know, however, that the potato field was on the edge of a meadow of a rich black soil, and that it received the wash of a narrow strip above on its whole length. These advantages would not, we should judge, bring such a crop of themselves.

The corn crop was carefully examined. The soil planted was treated much as was that for potatoes. Numerous questions were put, all of which were replied to minutely by the Doctor, stating the names of the fertilizers used, the quantity, and when applied.

The grass crop excited surprise. About twenty acres had been mown, and fifty tons, by measure, of as good hay as was ever stowed away, were upon the scaffolds and in the bays. It was bright, and as fragrant as a nosegay. We walked over the acres where this was cut, and found another crop which it was estimated would yield 1,500 lbs. per acre, or about seventeen tons more! Some of the acres would give a ton, as the thick herds-grass stood knee high!

The Doctor keeps five horses and some sixteen head of cows, and all the manure made in every way is used upon the farm. But where it has been employed the fact was stated. On one piece, a high and dry knoll, an experiment has been going on for seven years. Not a shovelful of stable manure has been added. Last year we saw the crop growing upon it, and estimated it at fully a ton per acre, but did not inquire what it was this year. It is the aim of the Doctor, and his advice to all is, to make all the manure possible, and use it on the farm. In most cases, this is not enough, — and here is where chemical fertilizers can profitably come in. By their aid, lands long languishing may be brought into a state of fertility, and gradually all the cultivated fields and the grazing lands be brought into a profitable condition.

THE DINNER, AND AFTER-DINNER TALK.

After a sumptuous dinner, the leading dish being a capital chowder, with fruits of the season, creams, ices, coffee, and tea, Dr. Nichols briefly explained his reasons for inviting his friends to meet him. They were *social* and *instructive*. He desired to learn of others, and in return to say something of his peculiar modes of cultivating the soil, and to show the growing crops to those present, in corroboration of the results of his practice. His remarks were received with demonstrations of approbation.

The Doctor then called upon Major Ben. Perley Poore, of West Newbury, who drew down "the Grove" by happy hits upon various practices. He dwelt mainly upon the progress and increased profits of scientific farming.

Upon being called upon, Gen. Sutton, of Salem, spoke in high terms of the effect of gatherings like the present upon the minds of farmers, and thought them of more importance than all the premiums paid out at the shows.

Mr. J. D. Lyman, of Exeter, late Secretary of State in New Hampshire, being called on, said farmers now acknowledge the relations of science with the practical affairs of agriculture, and continued for some minutes on this theme in his usual earnest and attractive manner.

The Editor of the Manchester *Mirror and Farmer*, John B. Clarke, Esq., responding to a call, said he knew no man to whom the farmers of New England are looking with so much interest as to our host of to-day. The attention he has called to the use of chemical agents as fertilizers for crops is universal among our people, and they are impatiently waiting for more light upon the matter. We have some results of chemical fertilizers about us to-day of the most gratifying character.

Hon. Allen W. Dodge, of Hamilton, spoke of the "hue-and-cry" against farming as being unprofitable. Farmers support all, he said, and with the aid of science will lead the nation on to an immense power and wealth.

Mr. Fay, of Chelsea, and Mr. Warren Ordway, of Bradford, made brief remarks, and then the party rode to a beautiful eminence on the farm, where they had a fine view of the city and surrounding country. From the farm they rode to the station, where the party separated, all highly gratified with the events of the day.

On the following day we had the pleasure of returning to the farm, and of looking over the buildings and crops in a more quiet way. We found all things in scrupulous order; every department of the buildings sweet and clean; the yards and roads inviting to man and beast. In the fields, weeds were underlings, and the whole presented an air of thrift and order which was worthy of imitation and refreshing to see.

Among the gentlemen who enjoyed this festive occasion, there were two who are quite extensive land-owners. Gen. Sutton, of Salem, has a large farm in the ancient town of Ipswich, and some three hundred acres, we believe, within the limits of the city of Salem.

Mr. Peirce, of the firm of Peirce & Bacon, Boston, has a farm at Ipswich, upon which he keeps one hundred head of stock, and is bringing it up to compete with the Garden of Eden as nearly as he can. He owns a very large extent of land in Texas, and now has 2,500 acres in corn, six hundred acres in cotton, and four hundred acres in sugar cane. He makes the town of Topsfield his home, and in his farm enterprises is endeavoring to ascertain what amount of crop an acre of land is capable of producing. This is just what New England farmers need; that men of financial, as well as of agricultural skill, shall make such experiments on New England soils as have been made by such persons on the soils of Old England. Skill and means to test the productive power of our soils, the best way to manage them, and the kind of crops to which they are best adapted, are wanted.

In the cold grapery of Dr. Nichols, we found eight varieties of grapes, now in the sixth year of their growth, and presenting a most luxuriant appearance. They *have never had any stable manure.* Most farmers can have one if they choose, and at little cost or labor.

BUTTER, CHEESE, AND MILK.

It requires about sixteen quarts of good milk to make one pound of butter, and ten quarts to make one pound of cheese.

It is often a question with farmers, how they can best dispose of their dairy products. If we consider that the pork produced from the butter-milk or whey pays for the extra trouble involved in the care of butter and cheese, the account will stand about as follows when butter is selling at forty cents a pound, cheese at eleven cents, and milk at three cents per quart: —

One pound of butter = 16 quarts of milk = 40 cents, or $2\frac{1}{2}$ cents per quart for milk.

One pound of cheese = 10 quarts of milk = 11 cents, or $1\frac{1}{10}$ cents per quart for milk.

In order to pay three cents per quart for the milk consumed, the pound of cheese would have to be sold at thirty cents, or one pound of butter at fifty cents.

In the neighborhood of large cities milk will command even better prices than the above, as it is frequently worth five cents per quart; this would bring the value of the pound of butter up to eighty cents and the cheese to fifty cents.

A farmer can easily judge from these figures which is the most profitable business for him, the prices being in all cases those which can be obtained on the farm. If the articles are to be delivered, the ratios may be somewhat changed.

For a person living a long distance from market, or where the means of communication are slow and uncertain, cheese will most likely be the only available means of reaching a market. For those living nearer to market, with good facilities for reaching it, butter is the best paying product.

In order to make milk pay, the market must not be over two or three hours' distance from the farm. Many railroads, however, equalize the rates of freight on milk, charging all their customers the same price, whether they live ten or thirty miles from the city.

THE "GRAFTON FERTILIZER."

A circular of the "Grafton Mineral Fertilizer Company" accidentally fell into our hands a short time since, and looking it over, the following affidavit attracted our attention: —

"*Whereas*, Dr. Nichols, of Haverhill, Mass., has recently read an essay before several large meetings of farmers and others in Massachusetts and New Hampshire, in which he pronounces the Grafton Mineral Fertilizer 'worthless, or nearly so.' Therefore we, the undersigned, farmers, and others of Grafton County, N. H., say, we have largely experimented during the past two years with this Fertilizer, and, as a manurial agent, have found it equal to superphosphates, and any other concentrated manures we have ever used, and have given our published statements in accordance with the above."

Appended to this document are the printed names of about *fifty* persons residing in the vicinity of the "mountain of manure" at Grafton, N. H., and the list is headed by Harry Bingham, a *lawyer*, of Littleton. This is so decisive and overwhelming, that there seems to be hardly a loophole for escape. If fifty men deliberately sign a document declaring that gold can be manufactured from lead, or that plants assimilate and thrive on dolomite rock powder, what is the use of declaring the thing impossible? The alternative is presented of believing the statement of fifty men, and declaring false and erroneous all that science and research have taught during the last century upon the nutrition and the food of plants, or doubting the verity of the statements and clinging to science. We intend no offence to the certifying gentlemen of New Hampshire, but our farm experience so decidedly verifies science, that we must follow its teachings a while longer.

A NEW BOOK ON MANURES.

It is seldom that we meet with a book on farming so well written, and containing so much that is really valuable, as "American Manures and Planter's Guide," by J. B. Chynoweth and W. H. Buckner, recently published in Philadelphia. The authors have given first a short practical treatise on the chemistry of the soil and of the plants growing thereupon, and have followed this by an examination of the various fertilizers for sale in the Philadelphia market. The chemical part of the work is well done, and is sufficiently full to give the farmer a tolerably good idea of what is really needed in the growth of plants. We notice some few errors that have crept into the text. On page 39, *marsh gas* is said to be the direct cause of the malaria of the ague. This we think is rather a broad statement, considering how little is really known upon the subject. On page 68, the authors, speaking of dolomite, call it "carbonate of magnesian lime stone;" it should be carbonate of magnesia and lime. On page 83, it is stated that "albumen and gluten enter into the composition of the bones." This they do only indirectly in the form of gelatine, which is an analogous proteine body. In giving the composition of the various plants raised for food, ammonia is spoken of as one of the constituents. This agent never exists in a free state in plants; it would have been much better to have given simply the amount of nitrogen. On page 115, it is stated that the origin of phosphoric acid in the soil is from the bones of animals. In reading this, perhaps some intelligent farmer might inquire where animals obtained their supply. There are a few other trifling errors of this kind which will doubtless be corrected in a new edition.

In the second part the preparation of special manures is treated of at length. We differ from the authors as to the value that should be put upon raw bones as a fertilizer. The value of bone phosphate depends almost entirely upon its mechanical subdivision; flour of bone, or bone in the form of dust, being almost as prompt in its action as superphosphate. They are not willing to assign them any value in the various fertilizers analyzed. We think, however, that their criticism is just, that when a manufacturer undertakes to furnish a certain article he should furnish that article, and not something else; and in estimating the value of the article furnished, no attention should be paid to the value of foreign ingredients. A strict reading of this rule would, however, throw ammonia out of the account in reckoning the value of a superphosphate of lime. The authors might allow the manufacturer of the various manures mentioned their price for insoluble phosphoric acid, and still make out a very strong case against him. We shall refer to these prices again in connection with some analyses upon which we are now engaged.

MANUFACTURER'S CATECHISM.

Every farmer desiring to purchase commercial fertilizers, will do well to commit to writing the following questions, which we copy from "American Manures," and present them to the manufacturer, and insist upon having them definitely answered. If the manufacturer will not give answers, he is either ignorant of his business or he is afraid of exposing the poor quality of the article furnished.

First. "What percentage of phosphoric acid, anhydrous, soluble in cold water, do you warrant your fertilizer to contain?"

Second. "What percentage of insoluble phosphoric acid, anhydrous, do you warrant your fertilizer to contain?"

Third. "What percentage of nitrogen as it exists in raw bone, blood, etc., do you warrant your fertilizer to contain?"

Fourth. "What percentage of actual ammonia do you warrant your fertilizer to contain?"

Fifth. "What percentage of potash do you warrant your fertilizer to contain?"

Sixth. "What percentage of water does your fertilizer contain?"

Seventh. "What percentage of *pure* potash is there in the 'salts of potash' contained in your fertilizer?"

Eighth. "What percentage of phosphoric acid is there in the 'soluble phosphate' contained in your fertilizer?"

To the above questions we would add one more. What is the source of the phosphoric acid — bones or mineral phosphate?

Having been furnished with true answers to

›e above questions, the farmer can easily deter-ne for himself whether it will be profitable to y or not, if he will inform himself of the value the agents as presented.

HINTS FOR THE FARMER.

To Keep Meat Fresh. — The following, from Rural American, will be useful to farmers who at a distance from meat markets: Cut the ›t in slices ready to fry. Pack it in a jar in lay- sprinkling with salt and pepper, just enough to ›e it palatable. Place on the top a thick paper ›loth, with salt half an inch thick. Keep this on the while. Meat has been kept perfectly good three weeks in summer by this method.

To Keep Ice. — Dr. Schwarz, a German chemist, › he has kept six pounds of ice for eight days by following simple recipe: Put the ice into a ›p dish, cover it with a plate, place the dish on a ›w stuffed with feathers (hen feathers will ›wer), and carefully cover the top with another ›w, thus excluding the external air. Feathers well-known non-conductors of heat, and thus ice reserved from melting.

Tanning Leather. — It is often a matter of ›convenience and economy in the household or ›he farm to be able to do a little tanning; so we here an approved receipt which may prove use- Soak the skin or hide eight or nine days in ›r, then put it in lime; take it out, and remove hair by rubbing it, and soak it in clear water the lime is entirely out. Put one pound of ›to three of salt, dissolve in a vessel sufficiently ›e to hold the hide; soak the hide in it three or days, then take it out, let it get half dry, and beat or rub it until it becomes pliable. Leather ›ared by this process will not do well for shoes, ›answers for hamstrings, back bands, and various ›r purposes on the farm.

Inspection of Agricultural Colleges. We find the following paragraph in one of exchanges: —

"Professor Gilman, of Yale, has, by the request ›e Secretary of the Interior, started on a tour ›spection of the Agricultural Colleges of the ›hern States, to collect information for the De-›ment of the Interior."

We hope that good dinners, and polite atten-›on the part of college officers, will not so ›the Professor that he cannot see the seri-›lefects in some of their institutions. If he ›mpetent and honest, we shall look for his ›rt with interest. If it is unfavorable, we the Department will hesitate to publish it, ›ereby some personal interests might be in-›red with.

Value of the Journal to the Farmer. — ›ers corresponding in statement with the one ›nted below are received by almost every mail, it is a pleasure to know that we are contribut-›o advance the great interests of agriculture: —

Dr. Nichols, — I inclose one dollar for the ›nt volume of the Journal of Chemistry. a most valuable help to the proper education of ›armer and mechanic. I am under great obli-›n to you for its pages, and I believe it has paid improved farm management *more than fifty its cost in a single year.* R. E. L."

Indiana dogs have carried sheep stealing to an extent, that the legislature has offered a ›ty on every dog-skin produced, and the honest ›ers now find puppies the most profitable crop can raise.

Boston Journal of Chemistry.

BOSTON, OCTOBER 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

Mr. A. D. Blanchard is no longer a Travelling Agent for the Journal. All money paid on Journal account should be sent directly to the office, 150 Congress Street.

STEAM BOILER EXPLOSIONS.

Since the article upon boiler explosions was published in the last number of the Journal, several of a very serious nature have occurred in various parts of the country. The explosion of a boiler in the neighboring city of Newburyport, by which seven persons were instantly killed, is a casualty as remarkable as it is sad and lamentable. This was comparatively a new boiler, made by a first-class manufacturer, and is reported to have exploded while under a steam pressure of only seventy pounds. We have not before us sufficient facts to enable us to discuss the casualty intelligently, and therefore we pass to the further consideration of causes of boiler explosions. The views expressed in our former article do not coincide with those of many intelligent and observing mechanics and engineers, and we were quite well aware that they would not, when we committed them to paper. The conviction that some other agent than steam is the immediate cause of the terrific explosions, remains firmly fixed in the minds of many. Until some *proof* is afforded that other agencies are present and acting in these occurrences, we must differ from our correspondents who have written to us upon the subject. The *fact* that a dead inorganic agent like carbonic acid gas, when gradually developed in a vessel as strong as a steam boiler, is found capable by simple mechanical pressure of rending such vessels, and producing all the violent and disruptive effects seen in the instances of steam boiler explosions, has an important bearing upon this question. We have seen copper vessels which withstood the hydraulic test of over three hundred pounds to the inch, torn into fragments by an explosion as instantaneous as that of gunpowder. No one can suppose for a moment, that any water decomposition, explosive gases, or electrical agencies had anything to do in causing these explosions. Why, then, is it necessary to suppose that any other agent but that of simple steam is involved in boiler explosions?

It is certain that explosions are not confined to old and defective boilers, neither are they always due to low water, or imperfect safety valves. We should feel a greater degree of safety in charge of a good, sound, strong boiler, with the usual connecting apparatus in good order, than with one of an opposite character; but under no circumstances should we feel that there was perfect exemption from danger. We believe that boilers are often greatly injured in passing through the testing process. The pressure is usually carried up to a point double of that which is required in the ordinary work with steam, and often this strain upon the boiler is carried to a still higher point. The effect of this upon the crystalline structure of the plates of metal is obvious; it is greatly disturbed, and the cohesive force is weakened, and hence when brought under the strain of suddenly evolved steam pressure, although exerting a force below the testing point, most disastrous results follow. A new boiler may be thus weakened, and it may be further weakened by excessive steam pressure often exerted upon it. Metals, as repeated experiments have proved, are singularly affected when subjected to a continuous strain, with and without the supplementary influence of heat. This subject deserves the most careful study, by intelligent and competent experimenters and engineers.

It is certainly curious how some old, rickety, condemned boilers will hold out under what are manifestly great abuses. We once took passage in a steamboat on one of our Western rivers, which was propelled by steam generated in a boiler apparently having not much greater strength than a section of ordinary stove-pipe. From a close inspection of the old rusty affair, we were convinced that a hole could have been made in it with a blow from a nail hammer, and yet the gauge indicated a pressure of seventy pounds to the inch. It is needless to say we felt relieved when that boat touched the wharf and we were safely on shore again.

We present the following extract from a letter received from a gentleman having charge of extensive iron works at Burlington, Iowa, as showing what the general feeling is regarding the cause of explosions, and also what recklessness prevails among those having charge of steam boilers: —

"That boilers are blown up and torn into strips by the pressure of steam alone, is hardly entertained for a moment by Western men generally. The West has been the great field of boiler explosions, and we have learnt by sad experience that something more terrific than even gunpowder is the agent of destruction. I examined to-day a boiler that was not in some places one sixteenth of an inch thick, yet it regularly carried one hundred pounds' pressure to the square inch, and at times higher. Not long since I saw (with not a hard blow) a centre punch driven

through a boiler so that steam escaped when it was carrying from ninety to one hundred pounds. It is no uncommon thing to cut out sheets from the bottom of locomotive boilers that are carrying one hundred and thirty pounds' pressure, that are so thin and frail that you can nearly punch them through with a jack-knife. I knew of an instance not long since where a man laid a bag of sand on the inside of his boiler over a crack in the shell, and wedged it down, fired up as strong as ever, running it several days, and carried more than twice as much steam as the *West-field.* The most terrible explosions that we ever experienced in this country have been with boilers comparatively new, carrying the ordinary amount of steam but a very few moments before the bursting. Whatever element it is that causes it, works with lightning speed, and your safety valve is as useless to relieve it as a gimlet-hole a keg of ignited gunpowder."

HARVARD UNIVERSITY.

QUITE extensive changes have been made in the college grounds, and several of the buildings have been altered since vacation commenced. Weld Hall is rapidly approaching completion. It stands between University and Boylston Halls, in line with the former. On the opposite side of the yard Matthews Hall is going up more slowly. This stands between the ends of Massachusetts and Dane Hall, which has been moved southward, in order to give room for the new hall. The Steward's office has been moved to the rear of the old "President's house." Boylston Hall has a new hat upon it in the shape of a Mansard roof. Part of this addition to the building will be occupied by the Peabody Archæological Collection; the remainder will be devoted to a laboratory for advanced students, to take the place of the Lawrence Laboratory. The roof of Holworthy has also been raised about two feet, thus increasing the height of the upper story.

And last, but not least, all the old brick buildings have received a coat of fiery red paint. We do not think this is an improvement, but are in hopes that it will soon wash off, or that its radiance will be somewhat mellowed with lapse of time. Outside of the yard, building has also been rapidly carried forward. The great dining-room of the Memorial Hall will be roofed in this fall, and the Holyoke House is ready for occupancy. This will make quite a valuable addition to the accommodations of the University, besides giving law and scientific students a chance to occupy college rooms. Lawrence Hall has been entirely remodelled. The main hall will be used exclusively for engineering and kindred branches, the room for drawing being located in the third story. The wing is devoted to the Rumford professorship; the upper portion being fitted up as a lecture room, while the lower part contains the professor's private laboratory.

THE LAWRENCE SCIENTIFIC SCHOOL.

SOME points connected with the history of this school may not be without interest to many of our readers.

In 1847 Abbot Lawrence erected and gave to the Corporation of Harvard College the building now known as Lawrence Hall, his intention being, so far as we have been able to learn, to found a school for educating young men in scientific pursuits. In order further to carry out this idea, the corporation obtained an order from the Supreme Court permitting them to pay the salary of the Professor of Chemistry from the fund left by Count Rumford for founding a professorship of "science applied to the art of living." E. N. Horsford, then a young man recently returned from Germany, was elected to this professorship, and held the position until the summer of 1863, although he occupied the chair only nominally for the last two years. In 1863, Dr. Gibbs was appointed professor, after a closely contested election. From this time the school steadily declined in numbers, not from any inherent defect, but from jealousies or animosities among those who had influence in its management. There had been disappointments on the part of some with regard to the choice of the Professor of Chemistry, and therefore encouragement was, it is alleged, withheld from the school, which was declared a failure at a time when it was paying all of its expenses from its own funds. At no time since 1863 has the school been in debt to the University, and at most times it has had a large surplus in the hands of the college treasurer.

Judging by the number of students in attendance, the school has not been a success, but judging by the standard of scholarship, and by the success of its graduates, it will compare favorably with any other institution in the United States if not in the world. Twenty-seven of its one-hundred and fifty-nine graduates hold, or have held, either professorships or assistant professorships; and this is certainly a distinguished record. Besides those who have graduated, there has hardly been a term since the school was organized when there were not among its members one or more professors of other colleges, fitting themselves for the better fulfilment of their duties. We have lately seen a letter from a gentleman connected with a college, in which he says, "I am very sorry that the school is removed from the care of Dr. Gibbs or changed in its organization. It was just what was needed; a place where a professor could go to brush up his rusty studies without being brought into contact with those who were studying merely because they had to do it." Under the changed organization it would appear to be brought into direct competition with the Institute of Technology, and the Sheffield Scientific School, and with the scientific departments in the various colleges scattered over the country. From having been a department of the University, it appears to be degraded into an appendage to the College. We fear little has been gained by the change, and perhaps much has been lost.

ECONOMY IN THE USE OF GAS BURNERS.

GAS is wasted in many ways, but the loss from the use of bad burners is in the aggregate probably greater than that from any other cause. A committee appointed by the London Board of Trade to examine into "the construction of gas burners with reference to the principle of gas illumination" have made their first report; and they estimate the amount that might be saved annually in London alone by the use of good burners as at least *two millions and a half of dollars*, or one fourth of the total expenditure. This is probably more than there is reason to expect will be saved, for many years to come, from any improvements in the manufacture of gas or any other reduction in the cost of supply. The committee sum up the results of their experiments as follows: —

1. In the case of the bat-wing and fish-tail burners there is a point of consumption above which every increase in the rate of consumption produces a decrease of light relative to the quantity of gas consumed. 2. The point of consumption at which each of those burners gives its maximum of light relative to the quantity of gas consumed, varies enormously — two burners with which experiments were made giving most light from the gas when the rate of consumption is only $1\frac{3}{4}$ feet per hour. 3. With argands, on the other hand, the light from the gas steadily increases in a higher ratio than the consumption. In other words, the larger the quantity of gas consumed in argands (up to the smoking point) the greater the amount of light obtained relatively to the quantity of gas consumed. 4. Alike with argands, bat-wings, and fish-tails, whatever be the rate of consumption at which the maximum of light is obtained (in other words, taking each of the burners at its best), there is nevertheless a striking difference in the degree of light obtained from the same quantity of gas, some burners giving a light equal only to 20, while others give a light equal to 60, 80, and 100. 5. The best argands give a nearly equal amount of light relatively to the quantities of gas consumed, the experiments with them tending to show that within the ordinary range of consumption the illuminating power of gas remains the same. 6. Finally, even as regards very low rates of consumption (rates, indeed, at which gas is never burned for illuminating purposes) the application merely of a rude apparatus for regulating the air-supply suffices to make only *two feet* of gas give a light equal in proportion to the greatest amount of light obtainable from the gas when consumed at any higher rate in a really good burner.

LIME IN MUSSEL SHELLS.

WE are greatly obliged to Professor Morse for the subjoined interesting remarks upon an item which appeared in a former number of the JOURNAL: —

In the August number of your excellent journal there is a query as to where the fresh-water mussel obtains its lime, with an instructive analysis of the shell, and of the waters of Lake Kenoza whence the shell was obtained; the shell possessing 14.7 grams of carbonate of lime, and the quantity of water containing a like proportion amounting to four barrels.

When we understand the habits of the fresh water mussel, we shall readily understand how it is that the animal secures the lime for its shell, even from water containing but an inappreciable quantity. If a living mussel be placed in water, it will soon be seen to slightly open its shell, and from one end two currents of water will be noticed, one passing into the shell, while the other current passes from the shell, as indicated in the diagram by the arrows. So strong are these currents, that if a dozen mussels are placed in

a uniform manner around the edge of a circular dish, a current is soon produced which will cause a miniature boat to sail round and round. The mussel not only appropriates the oxygen contained in the water which bathes the gills within, as in fishes, but having no hard parts to its mouth, or any ability to seize food, depends upon the minute particles of organic matter floating in the water which are constantly swept into the mouth by the same organs which cause the currents, namely — cilia. These cilia are microscopic lashes $\frac{1}{5000}$ o

an inch in length, which clothe the gills like down, and which keep up a perpetual movement.

Professor Jeffries Wyman has discovered some interesting properties in the ciliary motion of the cells of the fresh-water mussel. By carefully removing the gills with a pair of scissors, and placing them in a uniform direction on a wet board, their edges slightly lapping over each other, he has caused a slip of paper to which was affixed an upright wire with a wad of cotton at the end, to travel slowly from one end of the gill series to the other. Or, by placing the gill in the water, pinned to a float, the float has been propelled slowly along. As the mussel is almost always in action, it is obvious that many hundred barrels of water pass into the shell during its life-time. A shell four inches long is at least fifteen years old, as shown by Prof. Agassiz.

In portions of this country, as in the West, where the rivers flow through limestone regions, the same species of mollusk which in New England have a very thin shell, in the limy waters of the West have a very thick and ponderous shell. It has been noticed that some species of marine mollusks living in pure sea-water, where the calcareous salts are abundant, have thicker shells than when occurring near the mouth of our rivers, where the water is brackish and consequently containing less lime.

EDWARD S. MORSE.

EDITORIAL NOTES.

QUICK WORK. — An English journal gives the following illustration of what may be accomplished with the aid of steam and modern machinery, even on a single day's notice. A Manchester merchant required 1,500 pieces of prints for shipment to America next day. In spite of diligent search, he was unable to find the desired pattern. At 5 o'clock in the evening he went to see a large cotton printer at Harpeney, three miles distant from Manchester, who undertook to print the 1,500 pieces in the colors, to finish them and deliver them, boxed up and ready for shipment, at noon of the following day. He was as good as his word. At 3 o'clock in the afternoon the goods reached Liverpool, and were taken out by the steamer two hours later. We should hardly believe this possible, if the account were not endorsed by the *Manufacturers' Review*, whose authority on a question of the kind is not to be questioned.

CHEMICAL NOMENCLATURE. — The *Academy* gives an outline of a new nomenclature proposed by Professor Filopanti, of the University of Bologna, as a substitute for the one now in use. "He forms words on his system that shall express not only the chemical formulæ, but, where possible, some of the properties of the compounds. Hydrogen is *a*, oxygen *e*, nitrogen *i*, and carbon *o*; and these letters, the first four vowels of the alphabet, indicate at the same time the quantivalence of the elements in question. The other elementary bodies have names consisting of four letters, the first being invariably *u*, the last the vowel denoting the quantivalence, and the remaining intermediate two being consonants taken from the ordinary name of the element. Thus we have for chlorine *ucra*, calcium *ucle*, copper *upre*, silicium *usle*. To mark the number of atoms contained in a compound, consonants are employed of the following respective values: —

[illegible]	*c*,	*d*,	*f*,	*g*,	*l*,	*m*,	*n*,	*p*,	*r*;
[illegible]	2,	3,	4,	5,	6,	7,	8,	9,	0;

and numbers over nine are shown by a combination of the above letters, *de* being 3 atoms of oxygen, *man* 78 atoms of hydrogen, and so on. State of aggregation, degree of basicity, and other characteristics, are indicated by the position of the accent. In this new language water becomes *beca*, carbonic acid *cebo*, lime *bebuclee*, urea *bobecifa*, melissylic alcohol *velo...or*, and chloride of sodium *busdabucra*." [We give these as printed in the *Academy*, but suspect that carbonic acid should be *cebo* and lime *bebucle*.] The system is ingenious, and, like others that have been proposed, has its good points, but it will hardly commend itself to chemists as the *beau ideal* of a nomenclature; and so radical a change in the "short hand" of chemical language is not to be easily brought about, unless we can get an absolutely perfect substitute for what we now have.

THE POETRY OF ADULTERATION. — A British rhymer has given to the world, under the title of "Poisoning and Pilfering," his views with regard to the prevalence of adulteration in his native isle. The following are extracts from the book, as quoted by a reviewer: —

"Scarce an article bought — or it seems so to me —
Is really the substance you take it to be:
There is hair sold as wool, there is cotton for flax,
There is sugar for honey, and tallow for wax."

"And in cocoa — which doctors commend —
There are poisonous things without number,
For there sago and arrowroot blend
With chalk, and red ochre, and umber;
And potato, and sugar, and flour,
With oxide of iron and oil —
And the husk they put in, too, has power
The invalid's breakfast to spoil."

If these are fair samples of the verses, there is more truth than poetry in them.

Speaking of adulteration in England, the Commissioners of her Majesty's Inland Revenue, in a report just published, state that during the past year eight samples of medicines for internal use, examined under Excise supervision, were found to have been prepared from methylated spirit. They comprised sweet spirit of nitre, paregoric, and the tinctures of catechu, rhubarb, and cardamoms.

We have referred before to various ways in which the farmer on the other side of the water is cheated, some of them being quite equal to the "best efforts" of agricultural sharpers of Yankee birth. One of the latest tricks of the kind is mixing the seed of the wild charlock, or corn mustard, with turnip seed, which it closely resembles. But before being mixed it is heated to a temperature which destroys its germinating power; so that, when the mixed seed is sown, only the turnip comes up, and the fraud is not likely to be detected.

ENGLISH BOOKS. — Among the thousands of cultivated men and women who read the JOURNAL, there are many who will be pleased to know how they can readily procure books in the London market. Mr. Bernard Quaritch, 15 Piccadilly, London, whose advertisement appears in the advertising columns of this number, is *the American* London bookseller, and a gentleman thoroughly reliable and every way qualified to attend to all orders which may be sent to him from this side of the water. All *rare* books in every department of literature and science he has on hand, or will procure, if they can be found in England. We have entrusted to him our book orders for several years, and take pleasure in commending him to our readers.

AGRICULTURAL ADDRESSES. — We have consented to deliver the annual address at the Worcester North Cattle Show and Fair, at Fitchburg, Sept. 27th, and also at the Amesbury and Salisbury Agricultural Fair, Sept. 21st. As the October JOURNAL will reach many of our subscribers, certainly before the Worcester Fair, we make the announcement in this number.

CORRESPONDENCE. — A large number of letters continue to be received, the contents of which are of such a character that we cannot give them attention. We are led to believe that our patrons and friends suppose we have considerable leisure on our hands, and can attend to making researches and answering questions for their benefit as well as not. This is a decided mistake. Every moment of our time is occupied, and not a day passes that we are able to attend to all the duties pressing upon us. Our friends must remember this in their correspondence.

ATOMS.

THE chief, if not the only solvent of indigo blue, or indigotine, hitherto known and used, has been concentrated sulphuric acid; but it has been lately found that several other substances will answer the same purpose, as aniline oil, Venetian turpentine, boiling paraffine, stearine, and petroleum. — To hypochondriac and nervous people who are over anxious as to what they shall eat, the advice of Sir Richard Jebb may be recommended: "My directions will be few and simple: you must not eat the poker, shovel, or tongs, for they are hard of digestion; nor the bellows, because they are windy; but anything else you please." — In these days, when there is so much discussion concerning the origin of the minutest and simplest forms of life, it is evident that the legal adage, "De minimis non curat lex," is not likely to be accepted as a maxim in zoölogy. — Fly paper, which is sticky without being poisonous, may be made by melting some rosin in an iron vessel, adding sweet oil or lard enough to make it as thick as molasses when cold, and spreading the mixture with a brush on coarse brown paper. — An artesian well has been sunk to the depth of 2,800 feet, at Cohoes, N. Y. — According to a late writer, sun-stroke is due to the action of light upon the brain, exerted through the eye, and not, as generally believed, to an elevation of temperature; and it is asserted that, if the eye be properly shaded from the glare of the sun, any unusual precaution in the way of protecting the head and back of the neck may be dispensed with. — An "air-blast loom" has been invented in England, in which the shuttle is driven by means of the sudden release of a very small quantity of compressed air, acting directly upon the shuttle, without any of the complicated machinery required in former contrivances of the kind. — The cotton factory at Augusta, Ga., has paid dividends of 20 per cent. from the start, and a new one, to run 1,000 looms, is contemplated, if the requisite capital can be secured. — The bedding of the common people in Holland is generally made of *kapok*, a silky fibre from a tree gourd found only in the Indies, which, besides its cheapness, has the merit of not being attacked by moths or vermin. — Mrs. Mary Michaels, of Petersburg, Pa., aged one hundred and ten years, has come to a premature end by suicide. — In England, they are making chamber-sets, book cases, and other furniture of Southern or pitch pine, stained to imitate mahogany, or varnished with its natural color; and the material is to be commended as cheap, solid, easily worked, and durable. — The editor of the *Manufacturers' Review* has recently analyzed a "simple and harmless antidote for the opium habit," put up in Indiana and sold at sixteen dollars a bottle, and finds it to be a syrup containing a large amount of *sulphate of morphia*. — On this side of the equator all bean vines twine the same way, but in southern latitudes they go round the pole in the opposite direction; whereupon the *Rural Carolinian* raises the question, "How does the bean manage directly under the equator?" — The so-called jet ornaments fashionable nowadays are nearly all made in Bohemia of a fine black glass, which is quite as handsome as the real jet, and much less fragile. — There is a sugar refinery in Brooklyn, which cost two and a half millions, employs two thousand men, and turns out nearly half a million pounds of sugar daily; and there are several other establishments in the same city that are nearly as large. — The *Pall Mall Gazette* states that in India cases of leprosy have been cured with carbolic acid, and a recent Madras paper says that it has been used with success even in very advanced stages of the disease. — The subject of instructing women in domestic economy is attracting attention in Eng-

land, and an institution is soon to be established in London, under the direction of a lady, for the purpose of teaching the art of housekeeping. — A man in Illinois has gathered eleven thousand pounds of grapes from a single acre of his vineyard. — The orthography of the Flemish language having lately been modified by government authority, a printer demands from the King an indemnity of $18,000, on the ground that the sale of his stock of dictionaries is spoiled. — Some one spilled a small quantity of magenta on the sidewalk near our office about three weeks ago, which still shows very plainly, though we have had, meanwhile, several heavy rains; and at one time the sidewalk for a hundred feet on either side of the place was distinctly red, showing the wonderful coloring power of the agent. — Ultramarine, for which fifty years ago artists paid its weight in gold, is now made artificially in immense quantities, and is used for such common purposes as painting carts and wagons, and coloring wrapping-paper; it is very permanent, and altogether unaffected by the weather. — The Nile carries fifty-five billion tons of water into the Mediterranean in the course of a year. — An American reaping-machine has won a prize in Hungary, where it was tested in competition with nearly forty other machines. — The *Medical Archives*, of St. Louis, is one of the best of our medical exchanges, and we would remind our Western friends that we furnish it *with the* JOURNAL at three dollars a year, which is the regular price of the *Archives* alone. — Several children in Liverpool were poisoned by eating Calabar beans, which they picked up from refuse matter on a vacant lot, where it had probably been thrown from some ship or dock. — The first gas meter was invented by Mr. Samuel Clegg, in 1815, and was used at the Gas Works in Westminster, Great Britain.

LITERARY NOTES.

MESSRS. LINDSAY AND BLAKISTON, of Philadelphia, have recently published *A Manual of Midwifery*, by Alfred Meadows, M. D., Member of the Royal College of Physicians, etc.; the first American from the second London edition, with illustrations. It is one of the most convenient, practical, and concise books yet published on the subject. They also reprint Dillenberger's *Handy Book of the Treatment of Women and Children's Diseases*, according to the Vienna Medical School; translated from the German by P. Nichol, M. D., who has added valuable notes on the main differences between the Austrian and the British practice. Another of their new issues is Dr. G. B. Duchenne's *Localized Electrization*, and its Applications to Pathology and Therapeutics; translated from the third French edition, with notes and additions, by Dr. Herbert Tibbits; a work to which we shall have occasion to refer hereafter.

The Harpers have just published *Shakespeare's Comedy of The Tempest*, edited, with notes, by W. J. Rolfe; the second volume of their illustrated school and family edition of the poet. Among their other recent publications are Lyell's *Elements of Geology*, issued as one of the popular "Student's Series," and unquestionably a better manual of the science for educational use than any other of similar compass; Bush's *Reindeer, Dogs, and Snowshoes*, a journal of Siberian travel and exploration in connection with the Russo-American telegraph expedition, — a very interesting book about an almost unknown region; Abbott's *Frederick the Great*, which has attracted much attention during its serial issue, and is now put into handsome form for the library; and *Jefferson's Domestic Life*, compiled from family letters and reminiscences, by his great granddaughter, Sarah N. Randolph, — a most entertaining memoir, and an important contribution to American historical biography. They have ready, also, their *Handbook for Travellers in Europe and the East*, revised for its *tenth* annual edition. The matter is brought down to the summer of 1871, and the maps, plans of cities, etc., which we commended as a new and valuable feature of the last issue, have been largely increased in number. The book still is, as it always has been, the best of its class.

Messrs. Hurd and Houghton have lately published *Stories from Old English Poetry*, by Abby Sage Richardson, who has culled from Chaucer and Spenser and Shakespeare the stories that were sure to charm the children, and has been peculiarly happy in her way of telling them. We hope that she will make it the first of a series, drawing further material from the ample stores of our early poets and dramatists.

All these books may be found at Noyes, Holmes, & Co.'s, 117 Washington Street.

We have received the *Second Annual Report of the Massachusetts Bureau of Statistics of Labor*, — voluminous and valuable, — and various pamphlets, which our space does not permit us to notice in detail.

Medicine.

HUMAN LABOR UNDER HIGH TEMPERATURES.

OUR readers are aware that the Commissioners appointed to inquire into the probable duration of the coal supply in Great Britain, have just issued their report. They have come to the conclusion that the existing quantity of available coal would suffice for 1,273 years, at the present rate of consumption; but if this rate increases as it has done for the last fifteen years, the supply would be exhausted in 110 years. Making allowance for a probable diminution of this rate of increase, the time would be extended to 360 years. In these estimates it is assumed that coal existing at depths of more than four thousand feet is not available or "workable," since it would probably be cheaper to import coal than to raise it from greater depths, even if human labor could be carried on under the high temperature which must prevail there. It is an interesting question, what is the maximum temperature compatible with the healthful exercise of human labor. The Commissioners appointed a committee to make investigations on this subject, and the results are embodied in their report. The question was found to be very difficult to decide. Evidence was given of extraordinary temperatures endured in the boiler-rooms of steamers and in glass-houses. In some of these cases labor has been carried on without serious detriment to health where the thermometer has indicated 180° Fahrenheit. In these instances, however, the thermometer was chiefly acted on by radiant heat, and therefore did not indicate the actual temperature of the air. In an experiment made under the direction of the Committee, it was found that a thermometer exposed to the radiation from the boilers of a steamer indicated a temperature of 105°; while another thermometer in the same position, but carefully screened from the radiant heat, stood at only 78°. It is important also to observe that the men who work in these hot places have ready access to the external air, and avail themselves of numerous intervals in their labor to cool themselves. One of the medical witnesses, who had spent a great part of his life in tropical climates, stated that he had experienced a temperature of 125° Fahrenheit in the shade, and that this great heat was rendered endurable by the dryness of the atmosphere; on the other hand, he had felt a damp atmosphere almost intolerable at the comparatively low temperature of 86°. Mining work is done in a Cornish mine where the air is heated by a hot spring to a very high temperature, and is also by the same cause saturated with moisture. Dr. Sanderson was deputed to visit this mine and make an investigation. He found the highest temperature at the extremity of an excavation, where a stream of water entered at a temperature of 114½°. At a distance of a yard from the extremity the thermometer indicated a temperature of 103°; but at a distance of only ten feet there was access to air, where the thermometer stood at 81°. According to other evidence, the temperature of the air occasionally reached 123°. The miners remained in their workings six hours out of the twenty-four. Four men were employed at a time, of whom two were always at rest in the cool air, and the other two were not always at work. The total duration of each man's work was less than three hours in the twenty-four. No man remained more than fifteeen minutes in the heat at one time. The condition of each miner on retreating into cool air is described as one of complete exhaustion; but on allowing cool water to pour over his body, the distressing effect quickly passed off. Dr. Sanderson came to the conclusion that the occupation in question is not necessarily inconsistent with the enjoyment of vigorous health; but he found there were many men who after trying the work were compelled to desist on account of the distress and exhaustion which were produced. It is his opinion that labor is not practicable in moist air at a temperature equal to that of the blood, namely 98°, except for very short intervals; and this conclusion is in harmony with the other medical evidence. The question of the maximum temperature under which work could be carried on in a coal mine hinges in a great measure on the hygrometric condition of the air. The depth at which the temperature of the air would, under present conditions, become equal to the heat of the blood would be about 3,420 feet. Beyond this point it is very doubtful whether work could be carried on; but, assuming that within moderate limits expedients may be devised for reducing the temperature, the Committee considered that the depth might be extended to four thousand feet. It appears, then, that the greatest depth at which, in the present state of our knowledge and mechanical skill, it would *pay* to work a coal mine, is at the same time the greatest depth at which it would be possible to labor, on account of the temperature.

A FOUNDLING HOSPITAL.

DR. GEORGE BAYLES, in the *Medical Gazette*, of New York, gives the following description of the celebrated Parisian Foundling Hospital:

Throughout all Europe the necessity for foundling hospitals is recognized, and such institutions are liberally provided by the governments of France, England, Austria, Italy, Russia, and other countries, in the districts where they are most needed. Like insane asylums, however, they are found available in the prevention of crime only in districts within a certain distance, not exceeding a radius of from 25 to 30 miles: but within this circle their influence is clearly noticeable. The best-known of these is probably the Foundling Hospital of Paris, established by St. Vincent de Paul in 1620. The building now in use was formerly occupied as a convent, and in many respects is admirably adapted to its present use. The number of children under the charge of the officers of this institution three years ago was about 17,000, only a small portion of whom were allowed to remain long in the building after their reception. All foundlings and orphans, by the rules of this institution, are taken without distinction, and kept for ten days, when, if healthy and in good condition, they are sent into the country to be nursed. If sick from diseases contracted before or after admission, they are carefully tended, and allowed to remain until a change of location is decided to be safe and desirable. A plan is adopted in the reception of children, which prevents any distinction being made with reference to age, sex, or physical condition. A small retired court-yard opens on the street, through which the persons bringing children pass to a place in the wall where "*le tour*," a revolving box turning on a pivot, communicates with the interior of the building. In its

ıe infants are placed, and a sliding door on the out-de is closed to prevent the identification of the par-es bringing them. When this is done, the bell on ıe outside is rung, and the nurse on duty within pro-eeds to "*le tour*," takes out the child, and replaces ıe box in its original position. Ten or twelve are ceived in this manner every evening, and their arentage remains forever unknown. Some are ought there publicly, their names registered, and ıch marks put on them as will enable their par-ıts, who are compelled to part with them unwill-gly, to recognize and claim them should they de-re to do so; while others are transferred from the arious public institutions, principally from the Maternité," where they are born of indigent others, or those who die in giving them birth.

The interior arrangements of this admirable in-itution are as perfect as they could well be made. he building is divided into four wards, commodi-ıs, clean, and well ventilated. The top floor is in-nded for the sick, it being more silent and secluded an the others, and both the medical and surgical itients are placed in separate apartments. The wer floors are devoted to children in good health, ıd have their separate dormitories, refectories, ıd wash and play rooms. A sister of charity has harge of each ward, assisted by a corps of nurses umbering one to six children, who are replaced at ght by a force of equal size and efficiency, so that e same number is constantly on duty. The fur-iture is plain and strong, but cheerful and attrac-ve in appearance. The cribs are all simple, and nstructed of iron, supplied with soft mattresses ıd most faultless bed-linen, and are enveloped in ırtains of snowy-white dimity. Each one is num-ered, and has a ticket opposite, with the date of e occupant's birth and its name, if one has been ven it by the person from whom it is received. he peculiar American institution which Dickens ıs forcibly characterized as "the eternal, accursed, ffocating, red hot demon of a stove," is unknown the public institutions of Paris. At each end of e dormitories and large halls is a great open fire-ace, where cheerful wood fires, protected by wire ıders, are kept burning during the cold season. efore them the children are washed and dressed, d a padded shelf or a long couch is placed within suitable distance, on which they are allowed to lie d warm themselves before being put to bed again. is difficult to imagine a pleasanter sight than this, d it would cheer the heart of many a poor mother uld she see the more than maternal solicitude with hich these *enfants de la patrie* are tended and itched over by their kind-hearted nurses. Every ır hours they are taken up and fed, their regular et consisting of milk, thin barley, rice-water, and rb teas. The rates of mortality among the chil-en here received are great, but not unnecessarily considering the fact that many are taken when t a few hours old, and, in addition to an untimely posure to the night air, are deprived of that nu-ment which physiological science has decided to essential to life, and impossible of accurate imita-on.

Of the 17,000 children constantly under the arge of the institution, but few are allowed to re-ain long in the hospital. The rest are either arded in suitable country houses, adopted into orthy families, or, if old enough, apprenticed to a ade in the city. On coming of age, they are dis-arged with a small gratuity from the surplus nds of the institution, and sent out into the world seek their fortunes. Most of the boys either en-t or are conscripted into the army, where many them have attained honorable rank and distinc-on; while the girls, deprived of suitable protection, e too often corrupted by the evil associations with hich, in the immoral city of Paris, they are soon rrounded. Here we notice the first great defect in the French system of rearing foundlings, but the evil result of this abandonment of the young women at an early age is not necessarily a part of the plan as it should and will be adopted in America.

MEDICAL MEMORANDA.

Statistics of Suicide. — A late number of the *British Medical Journal* gives some interesting statistics and comments upon suicide, collated from the records of the inquests of the coroner of central Middlesex, from which it would appear that, of all causes of death, suicide is the most constant. The proportion of suicides to the population is one in 12,000 in England and Wales, while in the district in question it is about one in 13,000. The proportion in which the sexes commit self-destruction is nearly the same everywhere, being about five males for every two females. The ages at which suicide is committed are, for the seven years which the coroner reports, nearly the same. One in twelve are young people under twenty years of age; a larger proportion among people above sixty; and the remainder, nine tenths of the whole, are equally divided among people from twenty to forty years of age. A further analysis of the cases shows that, as a rule, women prefer taking poison and drowning themselves. Of twenty-three cases of female suicide, six were from poisoning and ten from drowning. Women seldom cut their throats or hang themselves, whilst of sixty-six cases of male suicide exactly one half chose these methods of self-destruction. Men are also more given to jumping out of windows and from the tops of high places.

Cantharides in Hydrophobia. — At the last meeting of the British Pharmaceutical Conference, Mr. H. Groves read a paper "On the use of blistering flies in hydrophobia," from which it appears that about thirteen or fourteen years ago a certain Nikititsch Levachoff, of Peklitz, in Russia, created a sensation by his cures of hydrophobia. His arcanum was supposed to be the *Cetonia aurata*, or rose beetle. The monks of Phaneromenos, near Eleusis, Greece, use the insect *Mylabris bimaculata* with equal parts of the leaves of the *Cynancum excelsum*, in doses of fifteen grains of the mixed powder. At the same time they cauterize the wound with boiling oil. In Tuscany there are one or two persons who are reputed to be able to treat successfully the bites of mad animals by means of a nostrum whose basis is supposed to be cantharides, or other insects with blistering properties. The *Cantharis vesicatoria* is found in several parts of Tuscany, where the peasants collect it by spreading cloths under the trees morning and evening, and shaking the insects out of the branches. The months of May and June are those in which the gathering takes place, and the fly prefers the olive tree to the poplar and ash, which it also frequents. They are killed by being plunged into weak vinegar, or by being held over the steam of the same. Afterwards they are dried as rapidly as possible in the sun, and are frequently turned over by a thickly gloved hand or by other means.

To Prevent Pitting in Small-Pox. — Dr. I. H. Bird (*Med. and Surg. Reporter*) uses an ointment made of charcoal and lard to prevent pitting in small-pox. This is applied freely over the surface of the face, neck, and hands, as soon as the disease is distinguished, and continued until all symptoms of suppurative fever have ceased. The application allays the itching, and seems to shorten the duration of the disease, and leaves the patient without a blemish, the eruption protected by the ointment not even showing signs of pustulation; the charcoal preventing the action of light, and lard that of air.

Uses of Carbolic Acid. — Dr. Lehlback uses carbolic acid in solution of 5 to 20 grains to the ounce of glycerine and water, as a dressing to wounds. The benefit was marked in arresting suppuration and exciting rapid granulation. In *carbuncles* he uses *carbolized poultices*, and after a forced or spontaneous opening of the carbuncle a solution of carbolic acid in glycerine, from half a drachm to one and a half drachms of the former to the ounce of the latter. In conjunctivitis he thinks it is valuable. In burns and scalds he esteems it of great value; using one drachm to six ounces of glycerine. In minor burns and scalds, one application of the ordinary crude fluid article will almost invariably arrest the pain in a few moments, and prevent subsequent vesication.

Transplantation of Bone. — M. Philipeaux has made some experiments upon guinea-pigs, tending to prove that bone taken from an animal may be transplanted upon another animal of the same species. M. Ollier had made similar experiments before, but they were made upon the same animal and grafted in the same opening wherefrom they had been taken. M. Vulpian says that an important condition of success depends upon the age of the animals.

The Cathedral and the Hospital. — When the French took Paris, the cathedral of Notre Dame seems to have had a very narrow escape, and the rumors which reached us of its having been set on fire were not without foundation. It was saved by the courage and devotion of the house-surgeons of the neighboring hospital, the Hôtel Dieu. About three o'clock on the morning of the 24th of May, M. Hanot, the house-surgeon on duty in the waiting-room, was aroused by a great noise. Casks were being rolled through an opening in a neighboring barricade to the place between the hospital and cathedral, and a lieutenant of the Nationals, with an armed force, was demanding at the gate to be furnished with gimlets, locksmith's tools, and a candle. They were about to set fire to Notre Dame. The director of the Hôtel Dieu was sent for; it was pointed out by him that there were nine hundred sick and wounded in the hospital, and that the destruction of the one building would necessarily involve that of the other. After a long and rough colloquy with the officer a respite was obtained, and reference was made to the Committee of Public Safety, and a promise given that the cathedral should not be set on fire till time had been given to remove the sick. At about eleven in the morning, however, the cathedral was seen to be on fire, and smoke was issuing from one of the windows. The six house-surgeons were refused the use of the fire-engine, but collecting together a crowd of women and children they made their way into the building; the smoke was so thick and suffocating that they were on the point of being driven back; but, with the help of a fireman, who gave his aid in spite of the prohibition of the Communists, they reached the source of the mischief and extinguished the flames. A burning brazier was found at the choir, and another by the high altar. The chairs, benches, etc., had been piled up around the pulpit as high as the great organ, and also round the statues of Christ and the Virgin; paper had been laid at the base of the piles. The flames were extinguished, windows were broken to let the smoke out, every part of the cathedral was visited, and a guard organized for the purpose of preserving the edifice from further incendiary attempts. It was not interfered with during the day, and at eleven at night this part of the city was in the hands of the troops, and the Hôtel Dieu and Notre Dame were safe. M. Hanot, one of the house-surgeons, who tells the story very graphically in the *Gazette Médicale de Paris*, deserves that his name should be remembered in French history.

The Pool of Siloam. — This venerable spring has not only lost its miraculous power of healing, but it appears to have become the source of disease instead. Referring to a case of scarlet fever, Dr. A. Fisher, a surgeon in the British navy, says: —

"I attribute the origin of this case to the use of the water at Jerusalem, and consider ourselves fortunate in having escaped with only one case of enteric fever among the seventy-two persons visiting it. Without the walls of Jerusalem the water appears to be very good, but inside it is received into vast tanks and reservoirs beneath the Harem area, and elsewhere. These, from what I saw in the excavations recently executed by the Palestine Exploration Society, are entirely without protection from receiving a large proportion of the sewage of the city, in some cases without even the slightest filtration through earth or other obstacle. At the fountain of Siloam and Pool of Siloam, the water distinctly tasted like soap-suds, brought down by the water from the baths, etc., close to the Temple inclosure."

A Critic Criticised. — The *Pall Mall Gazette* was very severe, the other day, upon druggists who make mistakes in putting up prescriptions, and suggested that it would be well to hang one of the offenders as an example. The article was suggested by a case which the writer reports as follows: —

"The latest instance of this kind is the death of a gentleman named Wall, living at Salcombe Regis, near Sidmouth, who sent the other day to a neighboring chemist for a mixture containing a small quantity of morphia. The chemist put a *scruple* instead of a *drachm* of muriate of morphia into the mixture, the result of this little mistake being the death of Mr. Wall."

Some one ventured to suggest that the critic had blundered, whereupon he comes out, a few days later, with the following: —

"In an occasional note on a recent instance of poisoning, the words 'scruple' and 'drachm' were transposed, so as to make it appear that the chemist had given the smaller instead of the larger dose; whereas, obviously, the reverse was the case."

The fact was, as we find from a report of the case elsewhere, that the druggist had put in a scruple (or twenty grains) of muriate of morphia instead of half a drachm of the *solution* of the same (equal to half a grain of the drug), the prescription being written in a very indistinct hand by Mr. Wall, who was in the habit of taking opium, and of prescribing for himself.

SYSTEM IN BRAIN WORK.

A correspondent of *London Society* says: "I know a remarkably able and fertile reviewer who tells me that, though over his midnight oil he can lucubrate articles with a certain sharpness and force, yet for quietly looking at a subject all round, and doing justice to all its belongings, he wanted the quiet morning hours. Lancelot Andrews says he is no true scholar who goes out of his house before twelve o'clock. Similarly an editor once told me that though his town contributors sent him the brightest papers, he always detected a peculiar mellowness and finish about the men who wrote in the country. I knew an important crown official whose hours were from ten to three. He had to sign his name to papers; and as a great deal depended upon his signature, he was very cautious and chary how he gave it. After three o'clock struck, no beseeching powers of suitors or solicitors could induce him to do a stroke of work. He would not contaminate the quality of his work by doing too much of it. He would not impair his rest by continuing his work. And so he fulfilled the duties of his office for exactly fifty years before he retired on full pay from the service of the country. And when impatient people blame lawyers for being slow, and offices for closing punctually, and shops for shutting early, and, generally speaking, the wider adaptation of our day to periods of holidays and rest, they should recollect that these things are the lessons of experience, and the philosophy of society and life."

SELECTED FORMULÆ.

Carbolic Acid Ointment. — The London *Pharmacist* gives the following recipe: —

Simple ointment, benzoated, 4 pounds troy.
Carbolic acid, crystallized, 3 ounces, 96 grains.

Liquefy the acid by immersing the vessel containing it in hot water, and when the ointment is about congealing add the acid, stirring well with a strong wooden spatula. Each drachm contains three grains. This ointment has been of excellent service in treating large superficial wounds, and ulcerating surfaces caused by burns, and in cutaneous eruptions of a parasitic nature.

Liquor Sedativus. — This is a combination often prescribed by English physicians in diseases complicated with febrile symptoms: —

Tinct. Opii Camphor.
Spts. Æth. Nit. dulc.
" Mindereri.
Syr. Simpl.
Aq. Camphoræ, āā part. æq.
M. et ft. solutio. Dose: a teaspoonful.

To increase the therapeutic effect of this mixture, 2 fl.ʒ of Tinct. Gelsemini, or 1 fl.ʒ of Tinct. Verat. vir. are often added to four ounces, to meet particular indications.

Belladonna Solution. — The *Georgia Medical Companion* recommends this formula: —

℞ Ext. Belladonna	ʒi.
Glycerine	℥i.

Mix well. Glycerine is a better solvent for belladonna than water, for the purpose of applying around the brow, to produce dilation of the pupil. It prevents the extract from forming a hard crust, and insures with more certainty its absorption.

Cucumber Ointment. — The *Pharmacist* gives the following formula for cucumber ointment: —

Take of oil of sweet almonds, seven fluid ounces.
Spermaceti, eighteen drachms.
White wax, five drachms.
Glycerine, one fluid ounce.
Green cucumbers, four pounds.

Cut the cucumbers in small pieces, mash them in a wedgewood mortar, let them macerate in their own liquor for twelve hours, express and strain; melt the almond oil, spermaceti, and wax together, by means of a water bath; add to it the strained liquor, stirring constantly so as to incorporate the whole together. Set aside in a cool place (an ice chest preferred) till it becomes hard, then beat with a wooden spoon, so as to separate the watery portion of the cucumbers from the ointment, pour off the liquor thus obtained, and mix the glycerine with the ointment without the aid of heat, by working it with the hands until it becomes thoroughly incorporated. Put up in four-ounce jars, cover with a layer of rose-water, and set aside in a cool place. The ointment prepared in this way will keep sweet and nice for twelve months. It is much esteemed by physicians and the public generally in the South and Southwest.

Pomatum for Chapped Lips. — The following is from the *Druggists' Circular*: —

℞ Lard	16 parts.
Cacao oil	24 "
Spermaceti	8 "
Yellow wax	3 "
Alcanna root	1 "

The substances are fused for a quarter of an hour at a gentle heat, then strained through a cloth and mixed with —

Oil of lemon,	
Oil of bergamot, āā	1-6 part.
Oil of bitter almonds	1-15 "

when the mass is poured into suitable vessels to cool.

Glycerine Cream. — This recipe is excellent:

Take of Spermaceti, four drachms.
White wax, one drachm.
Oil of almonds, two troy-ounces,
Glycerine, one troy-ounce.

Melt the spermaceti, wax, and oil together, and when cooling stir in the glycerine and perfume.

Preserving Meat. — Many methods have b introduced to meet the ever-growing want of E land — cheap animal food. Liebig's process been carried on very profitably at home as w as abroad; but the preparation of extract of m has been declared wasteful, from the small amou of stimulating material preserved, and the casti away of all albuminoid matters to the manure hea A new plan has been introduced by an engine whose experience in sugar refineries and other e tensive works in hot latitudes has ensured a prac cal and economical solution of one of the most i portant problems of the day. Mr. T. F. Henl does away with steeping the meat in water, and wi boiling and otherwise treating it in the most cost way. He simply squeezes a definite amount juice out of the fibre, and by mechanical desiccati preserves the latter intact. The pressed meat th obtained contains ten per cent. of alcoholic extra and salt, and over fifty per cent. of fibrine and oth albuminoid constituents. It is exceedingly rich, an so is the meat juice, which Mr. Henley evaporat in vacuum pans. The juice contains about 15 p cent. of alcoholic extract, and over 50 per cent. o albumen. The old method of abstracting water onl from the animal matter is relied on as the preserv tive, and the low temperature at which the evapor tion is carried on prevents any loss of flavor or oth deterioration. It is perhaps strange that so chea and simple a process has not been suggested befor The first works on an extensive scale are to b opened on the River Platte, at the Estancia Nuev Alemania, where cattle have been reared an fattened for the European markets. It is propose to slaughter three hundred bullocks daily, and sinc it is stated that the hides and feet pay the first cost of the bullock and of its slaughtering, the prospects of the undertaking are promising. — *British Medical Journal.*

Pollen from Beets. — Reading the remarks upon dust, in the August No. of the Journal, leads me to mention that some persons are much troubled with itching and inflammation of the eyes during the blossoming of beets, and that without contact with the plants, but simply from the presence in the air of very fine invisible particles emitted from the flower, and evidenced to the nose by a pungent aroma. I have had very sore eyes this summer from the above cause. J. Robe.

Mount Lebanon, N. Y.

Lawrence, Kansas, *July 14th*, 1871.

Jas. R. Nichols & Co., — Enclosed you will find $5, for which please send me "Cincho-Quinine." Send by mail immediately, as I am nearly out.

I find it preferable to the Sulphate, — all in fact that you claim for it. Do you prepare it in form of sugar-coated pills? S. B. Anderson, M. D.

Answer. We do not, as it is so palatable that it seems quite unnecessary to put the agent in that form.

Middletown, Conn., *Sept. 6th*, 1871.

Jas. R. Nichols & Co., — I have made trial of your preparation of Cod Liver Oil with hypophosphites of lime and soda, in the case of a young man suffering from pulmonary turberculosis. The preparation had a very prompt and decided effect, in arresting the night sweats, relieving cough and dyspnœa, and in fact improvement has taken place in every respect. I shall continue its use.

J. Morgan, M. D.

Professor Wurtz has stated to the French Academy of Sciences that the nitrate of strychnia, used hypodermically, is an antidote to the poisonous effects of chloral.

Boston Journal of Chemistry.

Volume VI. BOSTON, NOVEMBER, 1871. Number 5.

Familiar Science.

[Communicated to Boston Journal of Chemistry.]

AN EXPLOSION ON THE SUN.

On the 7th of September, between half past twelve and two P. M., there occurred an outburst of solar energy remarkable for its suddenness and violence. Just at noon the writer had been examining with the telespectroscope [1] an enormous protuberance or hydrogen cloud on the eastern limb of the sun.

It had remained with very little change since the preceding noon — a long, low, quiet looking cloud, not very dense or brilliant, nor in any way remarkable except for its size. It was made up mostly of filaments nearly horizontal, and floated above the chromosphere [2] with its lower surface at a height of some 15,000 miles, but was connected to it, as is usually the case, by three or four vertical columns brighter and more active than the rest. Lockyer compares such masses to a banyan grove. In length it measures 3′ 45″, and in elevation about 2′ to its upper surface — that is, since at the sun's distance 1″ equals 450 miles nearly, it was about 100,000 miles long by 54,000 high.

At 12.30, when I was called away for a few minutes, there was no indication of what was about to happen, except that one of the connecting stems at the southern extremity of the cloud had grown considerably brighter, and was curiously bent to one side; and near the base of another at the northern end a little brilliant lump had developed itself, shaped much like a summer thunder-head. Figure 1 represents the prominence at this time, *a* being the little "thunder-head." [3]

Figure 1.

What was my surprise, then, on returning in less than half an hour (at 12.55), to find that in the mean time the whole thing had been literally blown to shreds by some inconceivable up-rush from beneath. In place of the quiet cloud I had left, the air, if I may use the expression, was filled with flying *débris* — a mass of detached vertical fusiform filaments, each from 10″ to 30″ long by 2″ or 3″ wide, brighter and closer together where the pillars had formerly stood, and rapidly ascending.

When I first looked some of them had already reached a height of nearly 4′ (100,000 miles), and while I watched them they rose with a motion almost perceptible to the eye, until in ten minutes (1.05) the uppermost were more than 200,000 miles above the solar surface. This was ascertained by careful measurement; the mean of three closely accordant determinations gave 7′ 49″ as the extreme altitude attained, and I am particular in the statement because, so far as I know, chromospheric matter (*red-hydrogen* in this case) has never before been observed at an altitude exceeding 5′. The velocity of ascent also, 166 miles per second, is considerably greater than anything hitherto recorded. A general idea of its appearance when the filaments attained their greatest elevation may be obtained from Figure 2.

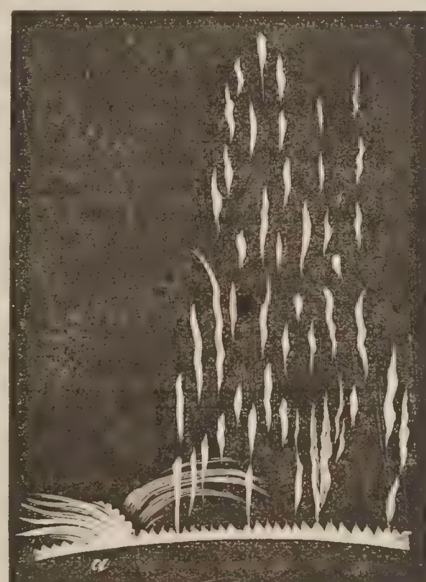

Figure 2.

As the filaments rose they gradually faded away like a dissolving cloud, and at 1.15 only a few filmy wisps, with some brighter streamers low down near the chromosphere, remained to mark the place.

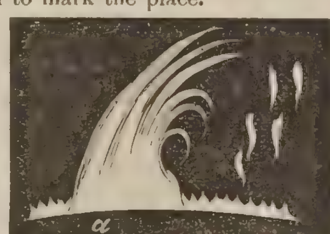

Figure 3.

But in the meanwhile the little "thunder head," before alluded to, had grown and developed wonderfully, into a mass of rolling and ever changing flame, to speak according to appearances. First it was crowded down, as it were, along the solar surface; later it rose almost pyramidally 50,000 miles in height; then its summit was drawn out into long filaments and threads which were most curiously rolled backwards and downwards, like the volutes of an Ionic capital; and finally it faded away, and by 2.30 had vanished like the other. Figures 3 and 4 show it in its full development; the former having been sketched at 1.40, and the latter at 1.55.

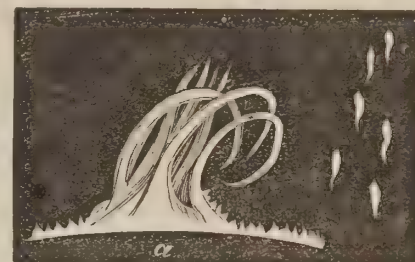

Figure 4.

The whole phenomenon suggested most forcibly the idea of an *explosion* under the great prominence, acting mainly upwards, but also in all directions outwards, and then after an interval followed by a corresponding in-rush: and it seems far from impossible that the mysterious coronal streamers, if they turn out to be truly solar, as now seems likely, may find their origin and explanation in such events.

The same afternoon a portion of the chromosphere on the opposite (western) limb of the sun was for several hours in a state of unusual brilliance and excitement, and showed in the spectrum more than 120 bright lines whose position was determined and catalogued, — all that I had ever seen before, and some 15 or 20 besides.

Whether the fine Aurora Borealis which succeeded in the evening was really the earth's response to this magnificent outburst of the sun is perhaps uncertain, but the coincidence is at least suggestive, and may easily become something more if, as I somewhat confidently expect to learn, the Greenwich magnetic record indicates a disturbance precisely simultaneous with the solar explosion. C. A. Young.

Dartmouth College, *September*, 1871.

[1] This is the name given by Schellen to the combination of astronomical telescope and spectroscope.

[2] The *chromosphere* (called also *sierra* by Proctor and others) is a layer of hydrogen and other gases which surrounds the sun to a depth of about 7,000 miles. Of this the prominences are mere extensions.

[3] The sketches do not pretend to accuracy of detail, except the the three *rolls* in that are nearly exact.

HOW ARTIFICIAL STONES ARE MADE.

A recent visit to the works of the Union Stone Company at Chelsea, Mass., afforded full opportunity to learn regarding the materials used, and the methods employed by the Company in fabricating their artificial stones and other industrial products. The works are quite extensive, and very conveniently situated to facilitate the peculiar manufacture to which they are devoted. They are upon the edge of the marsh, and a creek which connects with Mystic River winds around the yard, and the water is of sufficient depth to permit vessels of considerable tonnage to approach the wharf to discharge cargoes of raw materials, and receive the completed products.

The process adapted by the Company is essentially that of M. Sorel, the eminent French chem-

ist, who in discovering that the oxychloride of magnesium was a hydraulic cement of great strength and hardness, laid the foundation of a new manufacture which promises to be of great importance. The process, stated in the fewest words possible, is as follows: A solution of chloride of magnesium, of the proper strength and in the proper proportions, is added to the oxide of magnesium; this forms the cement; and sand, powdered marble dust, slate, or other material, forms the bulk of the body held together by the cement. A beautiful and durable sandstone for window caps, sills, steps, etc., is formed by incorporating the cement with clean beach sand. The color and hardness of the articles correspond with the sandstone hewn from the quarries in the valley of the Connecticut, and buildings constructed of it will be equally elegant and durable. Beside the stones, the Company manufacture soapstone sinks, stoves, etc., marble mantles, emery wheels, whetstones, hones, and balls for billiard tables. It is quite impossible to fix a limit to the articles of the greatest utility which may be made by this process. The soapstone articles are made by using the waste powder of the soapstone workers, and this is re-formed into very perfect stone by aid of the cement; so also, the marble is made by utilizing the fragments from the marble yards.

Of course, the prominent question which comes up in the mind of every one whose attention is called to the matter is, "Will it pay?" Can stones be made as cheaply or cheaper than they can be quarried in rock-producing sections? Another important question also arises, Will these artificial stones be as durable and safe building materials as the natural products? The last question we will answer at once; *they will.* The chemical nature of the artificial stone is such, that it becomes as hard as granite, and there cannot be a doubt that it will subserve all the desirable purposes for which that material is employed. It resists the action of frost, steam, acids, and other disintegrating influences as well as any of our best building stones.

The cost depends upon the cheapness at which the cement can be supplied, and the Company conclude that after two years of investigation and experiment they have "touched bottom" in this direction. At first, they were compelled to purchase the magnesia element of druggists at high cost, and also the chloride of magnesium was procured with difficulty, and they labored under great disadvantages till they learned that in one of the islands in the Grecian Archipelago (Negropont) a deposit of pure *magnesite* existed, and specimens were procured for experiment. It was found that the deposit was carbonate of magnesia with only *three per cent.* impurity, and a cargo of eight hundred tons, specially shipped and landed at the works, cost only \$19 *the ton!* This was certainly better than paying ten cents a pound for the article to the apothecaries. It was soon learned that "*bitterns,*" a waste product of the seaside salt works, supplied the liquid chloride needed to perfect the cement, and so the problem of cheap cement was solved.

And now we pass to consider briefly the process of manufacturing the stone article. The beautiful white lumps of the Grecian magnesite are knocked to pieces with a sledge hammer, and then they are thrown into a brick kiln and calcined, or heated to redness to expel the carbonic acid. This converts them into oxide of magnesium, which is taken, when cold, and ground to an impalpable powder; this is kept from the air, in large wooden bins. The bittern waters (solution of chloride of magnesium) are brought to the factory in casks and poured into large iron tanks, which are elevated so that they can flow through pipes to the point where they are mixed with the stone-forming materials. The calcined magnesia, ready for use, costs about two cents a pound, the bitterns perhaps four cents a gallon. Now to make a cubic foot of stone,

100 lbs. of beach sand are used, costing		.05
10 " " comminuted marble	"	.02
10 " " calcined magnesia	"	.20
10 " " bittern water	"	.02
		.29
Labor	"	.20
		.49

A cubic foot of stone, which now costs say fifty cents, formerly cost the Company nearly double that sum; and with the present high prices which are paid for labor, by quarrymen, the artificial product can fairly compete with the finished stones from the quarries.

The mixing is a very simple process. The sand and the magnesia are weighed together and mixed with a hoe upon a floor, and as the mixing goes on, the bitterns are gradually added so that a moist granular mass results. This is shovelled into a mould, tamped firmly with a mallet, and the finished product put away to "set." The "setting" or hardening process is accomplished in about a day, but the stones are not used until a month after they are manufactured. No heat whatever is employed, save in calcining the magnesite. Only about ten per cent. of the magnesia moistened with the liquid bittern water is required to hold together firmly the particles of sand so as to make a durable and beautiful stone. The chemical result is due to the combination of the chloride with the oxide of magnesium; and this, covering each particle of sand with a thin film, causes the mass to adhere together with such solidity, that it is capable of resisting a crushing weight of more than 20,000 lbs. to the square inch. The stones can be made of any form or size, and ornamented in any way which may be desired.

The Union Company are giving special attention to the manufacture of emery wheels and whetstones, and these products are of superior excellence. They have great tensile strength, and their cutting qualities are all that can be desired. In the proof trials, the wheels are made to revolve with a velocity of three miles per minute at the circumference, and they will not break under the immense velocity of four miles per minute. In the manufacture of the wheels it becomes necessary to bevel the cutting surface of some of them, and as this cannot be accomplished in the mou'd, it must be done by a cutter of some kind. Now what can be found that will cut an emery stone? a material so excessively refractory that a file of the hardest steel is rapidly torn into fragments when brought in contact with it. The implement used is a little *diamond*, and with this fixed into a holder, and the wheel made to revolve, the stone is cut as readily as a billet of wood in the lathe of the turner. The cutting edge of the diamond brought continually in contact with the hard emery for six months, is not sensibly dulled or in any way injured. In the manufacture of th wheels and other products, it has been foun that simple pressure applied to the materials i the moulds, does not cause the particles to co here together, and tamping or concussion i necessary. Mr. Elliot, the superintendent of th works, has contrived some most ingenious ma chines for facilitating the manufacture, and fo these he deserves much credit. The Compan have made a very large number of experiment and have persevered under many difficulties un til they have attained success. They have se cured patents which cover the most importar manipulating processes adopted by them. W are under obligations to Mr. John F. Wood, th Treasurer of the Company, for information, an for affording the fullest opportunity for inspec ing the work.

THE NEW "PSYCHIC FORCE."

THROUGH the politeness of Mr. Colman Se lers, of Philadelphia, we received advance shee of the *Journal of the Franklin Institute*, contai ing his paper, "Remarks on Experimental Inve tigations of a New Force, by Wm. Crookes, F. I S." In this paper Mr. Sellers endeavors to sho that Prof. Crookes has been most decided duped by Home the "medium," and that the o currences which took place in connection wi him were nothing but *tricks*. The oscillati board experiment, and that with the accordio described by Prof. Crookes, Mr. Sellers regar as of easy imitation, and in cleverness scarce rising to a level with the sleight-of-hand perfor ances of travelling mountebanks. Mr. Sellers probably one of the most accomplished mechan cians in the country, and he has contrived son beautiful and intricate pieces of machinery; a further, he is not only a maker of mechanic puzzles, but he possesses in an eminent degr the capability of using them skilfully. He is short known in private among his friends as a *pre tidigitateur* of the highest excellence. We spe of this, because it indicates his eminent fitness judge of the nature of mechanical contrivanc designed to deceive and puzzle the inexperience

So far as the experiments go which are carefully described by Prof. Crookes, we do n regard them as of much importance. They a certainly trifling and insignificant, compared wi phenomena of a similar nature which might u doubtedly have been observed in hundreds private families in London, at the time of his i terview with Home. The three gentlemen, fro their mental discipline and experience in r search, ought not to have been easily deceive they ought not to have fallen easy victims to t clumsy tricks of a charlatan, or one skilful prestidigitation. Recent advices from Mess Crookes, Huggins, and Cox, state that continu and more diversified experiments had been mad all of which were confirmatory of the genuinene of the phenomena, and tended to fix the belief the existence of the new "psychic force." R. Varley, F. R. S., the eminent electrician, h written a long letter to Prof. Crookes in whic he describes what he "has seen," and urges hi to continue his researches, intimating that h himself believes the disturbances to be the wor of "disembodied spirits." They propose to for a Psychological Society to be composed of twen or thirty competent gentlemen, whose speci work it shall be to meet every fortnight an

carefully investigate the phenomena. We do not think much will come of this, as "committees of investigation," and societies established to perform special work, are usually composed of very incongruous materials, and are apt to quarrel among themselves at an early period in their labors.

As regards the phenomena; after attempts at investigations, extending over a period of nearly a quarter of a century, and after having been brought in contact with every phase of it, we are unable to give information as to *how* it may be "investigated." Every mechanical, chemical, philosophical appliance, so far as we know, fails to elucidate any principle or shed any light upon the nature of the phenomena, and we shall be glad to be led out of the darkness by the English philosophers. We have found it quite easy to imitate many of the mechanical movements, sounds, etc., by the aid of electro-magnetism, chemical reactions, and mechanical contrivances. Twenty years ago we constructed an electro-magnetic device which gave the "rappings" perfectly, and by artfully arranging it in a room, we were able to deceive for a long time a wide circle of intelligent friends, and were looked upon as a "medium." The movements of small tables, chairs, etc., after the manner of the *true* "psychic force," may be readily imitated by any ingenious mechanic, give him *time enough* to construct the devices and a *proper place* in which to arrange them.

Undoubtedly we should be greatly interested in Mr. Sellers's ingenious performances, and quite possibly they are so skilfully arranged that, with all our experience, we might fail to detect his methods, or the source of his tricks; still there must be a wide difference in the *conditions* under which he is able to exhibit them as contrasted with what is seen every day in hundreds of private families in every State in the Union.

None of the performances of Mr. Home, or the "Fox girls," or the Davenports, or any other of the professional mediums, would probably convince us of the reality of the phenomena in question.

We have often attempted to investigate them as observed in the families of our most trusted friends, families where the moral uprightness and high character of every inmate rendered suspicion impossible. It has not been our business however to permit this known condition of things to deter us from the most thorough and persistent search, and we believe if the astounding physical disturbances witnessed had been due to secret springs, wires, electro-magnets, etc., we should have found them. No, the prestidigitation theory fails to explain the phenomena, and so do ventriloquism, sleight-of-hand, and all such tricks and devices. Science, within its present boundaries, has no methods for explaining or investigating it, and here we seem to stand at the present time. We may as well call it the "psychic force" as to employ any other term, and certainly while Prof. Crookes and his illustrious associates will probably fail to shed much light on the dark subject, they ought not to be ridiculed and abused by their equals, much less by those who are vastly their inferiors in every department of learning. In research and knowledge of physical science, Prof. Crookes and Mr. Huggins are certainly the equals of any men living.

NOTES IN FAMILIAR SCIENCE.

Some Facts about Fermentation. — The little organisms which cause fermentation are soft and wet; moisture constitutes a great part of their substance, and in a dry medium they cannot live. Applications, therefore, of a mere drying process are among the most important agencies for preventing fermentation. Germs of putrefaction or decomposition may be present in fruit, but if we merely take away the greater part of the moisture, we render the substance incapable of decomposing. Among the agents which serve for that purpose, there are some which abstract the water, not in a state of vapor, but in the liquid state. If we put a piece of fresh meat in contact with salt, or rub it over with salt, the salt gradually absorbs the water. The action is truly a drying action upon the meat, and it is effectual. In like manner, it is known to many persons that sugar is used just as salt. Ordinary jam — fruit and sugar which have been boiled together for some time — keeps better if the pots into which it is poured are tied up while hot. If one pot of jam be allowed to cool before it is tied down, little germs will fall upon it from the air, and they will retain their vitality, because they fall upon a cool substance; they will be shut in by the paper, and will soon fall to work decomposing the fruit. If another pot, perfectly similar, be filled with a boiling-hot mixture, and immediately covered over — though, of course, some of the outside air must be shut in — any germs which are floating in it will be scalded, and in all probability destroyed; so that no decomposition can take place.

Fossil Elephants in Alaska. — It has been generally supposed by scientific men that the fossil elephant of Siberia had no representative in the same latitude on this continent. Recent examinations on the Yukon River in Alaska, however, have established the fact that the remains are even more plentiful on the west than on the east side of the North Pacific. Enormous quantities of bones are found, and a supply of ivory sufficient to last the world for centuries. The valleys of all the streams and all the low grounds are filled with bones and tusks, so that every vessel now arriving from those remote possessions has part of its cargo made up in part of these new-found remains. The elephant, whose range was formerly almost universal, is now confined to a small portion of Africa and Asia, and it would seem as if the species was in process of slow extinction. Neither Europe nor America, which once swarmed with them, has now either a climate or vegetation fitted to their existence. Their remains however, are likely to give Alaska a value not previously suspected.

The Cow Tree. — Of this singular tree, the *Galactodendron utile*, Humboldt says: "Among the many curious phenomena which presented themselves to me in the course of my travels, I confess there were few by which my imagination was so powerfully affected as by the cow tree. On the parched side of a rock on the mountains of Venezuela grows a tree with dry and leathery foliage, its large woody roots scarcely penetrating into the ground. For several months in the year its leaves are not moistened by a shower: its branches look as if they were dead and withered; but when the trunk is bored, a bland and nourishing milk flows from it. It is at sunrise that the vegetable fountain flows most freely. At that time the blacks and natives are seen coming from all parts, provided with large bowls to receive the milk, which grows yellow and thickens at its surface. Some empty their vessels on the spot, while others carry them to their children. One imagines he sees the family of a shepherd who is distributing the milk of his flock."

The *Milk Journal*, commenting upon this description, remarks: "Our English climate would scarcely be congenial to this lactiferous tree, or this would present a fine opportunity for the Acclimatization Society; for what a solution it would be to the perplexities of the 'milk pail,' with its contents of typhoid-producing water and milk, contaminated with the germs of pleuro-pneumonia and foot-and-mouth disease, if every householder could have his own cow in his garden without awaking the ire of his neighbors, or the just indignation of sanitary inspectors. We are afraid, however, that if exposed to the scrutiny of our Laboratory, the vegetable milk would hardly be admitted to the 'genuine list,' but would be found to keep the word of promise to the eye to break it to the sense."

War and Vegetation. — Among the evil effects of the war it has been observed that in the vicinity of the scenes of great battles vegetation has been generally if not entirely destroyed — at any rate, materially impaired. German chemists explain the phenomenon as arising from the diffusion of sulphur in the air and over the surface of the soil. This sulphur, in the shape in which it is contained in the smoke of gunpowder, is supposed to combine with the oxygen in the atmosphere to sulphurous acid, a deadly poison in its effects on organisms of any kind.

Phosphorescence. — M. Panceri, in a paper presented to a scientific association, at Turin, claims to have established that the phosphorescent substance in fishes, in whatever part of the body it may be situated, is always fat, and that the phenomenon is due to its slow oxidation in contact with air. The skin of fishes is permeable to gases, and the oxidation of the subcutaneous fat proceeds without difficulty. Phosphorescence shows itself, as a rule, some time after death, and continues until putrefaction commences; as soon as a true decomposition sets in, accompanied by the disengagement of ammonia, phosphorescence ceases. Phosphorescence is prevented by the presence of fresh water, alcohol, or carbonic acid; oxygen, on the other hand, strengthens the phenomenon.

The Tints of Autumnal Foliage. — Mr. Sorby, in a recent number of the *Quarterly Journal of Science*, comes to the conclusion that the production of the fine tints of autumn is an evidence of diminished vital powers of the plants. This generalization also agrees with the fact that the unhealthy branches of a tree turn yellow, while the rest remain green, the subsequent development of more sombre tints being proof of more complete death.

An Artificial Whirlwind. — The fact that whirlwinds are caused by upward currents of heated air, was recently demonstrated in the town of Queensburg, N. Y. A farmer having occasion to burn a yellow pine fallow of some twenty acres, fearing that the fire might spread into the adjacent timber, ignited the fallow in several places on the edge, after taking the precaution of cleaning off the brush from a strip surrounding it. The flames rushing toward the centre from every direction, the air and smoke soon assumed a rotary motion, which increased in intensity. This whirlwind — for such it was — after becoming fairly formed, moved with wonderful velocity on its axis, tearing up small trees by the roots and lifting them into the air, stripping the branches from some that adhered too firmly to the ground, and fairly wringing the bark from others. It was accompanied by a noise resembling thunder, and lasted from five to ten minutes, but did not pass the bounds of the fallow, although it swayed back and forth across the field of fire several times.

HOUSEHOLD RECIPES.

Laundry Polish. — Take two ounces of fine white gum arabic powder, put it into a pitcher, and pour on a pint of water; and then having covered it, let it stand all night. In the morning pour it carefully from the dregs into a clean bottle, cork it, and

keep it for use. A tablespoonful of this gum water, added to a pint of starch made in the usual manner, will give to lawns, either white or printed, a look of newness, after they are washed. It is excellent as a polish for shirt bosoms and other starched linen.

To Clean Looking-Glasses. — Take a newspaper, fold it small, dip it in a basin of clean cold water. When thoroughly wet, squeeze it out as you do a sponge; then rub it pretty hard all over the surface of the glass, taking care that it is not so wet as to run down in streams; in fact, the paper must only be completely moistened, or dampened, all through. Let it rest a few minutes, then go over the glass with a piece of fresh newspaper, till it looks clear and bright. The insides of windows may be cleaned in the same way; also spectacle-glasses, lamp-glasses, etc. White paper that has not been printed on is better; but in the absence of that a very old newspaper, on which the ink has become thoroughly dried, should be used. Writing paper will not answer.

To Preserve Fresh Flowers. — Heat fine white quartz-sand in an iron pot, and stir in some stearic acid and spermaceti, using half an ounce of each to every five pounds of sand. Taken from the fire, the whole is well mixed, and used as follows: A small box, with a drawer lid, with the bottom knocked out, is inverted, and a coarse piece of wire gauze placed inside, over the lid, which now forms the bottom. This sieve is then covered with a layer of the prepared sand. The flowers, properly trimmed, are then placed on this sand, and completely embedded in more of it, to keep them in position. The box, covered with paper, is then placed in a room or oven, in which a temperature of one hundred to one hundred and ten degrees Fahrenheit is kept up, in which they will soon be dried. When this point is reached, the lid of the box is drawn, which causes the sand to fall out, leaving the dried flowers on the gauze.

Peach-Leaf Yeast. — One of our Southern exchanges gives the following recipe: Take three handfuls of peach-leaves, and three medium sized potatoes; boil them in two quarts of water until the potatoes are done; then take out the leaves and throw them away; peel the potatoes, and rub them up with a pint of flour, adding cool water sufficient to make a paste. Then pour on the hot peach-leaf tea, and scald for about five minutes. If you add to this a little old yeast, it will be ready for use in three hours; if you add none, it will require to stand a day and a night before use. Leaves dried in the shade are as good as fresh ones. As this is stronger than hop-yeast, less should be used in bread-making.

Welsh Rarebit. — Put into a frying-pan a quarter of a pound of cheese cut up into thin slices. Pour on it half a pint of sweet milk. Stir in an egg that was already beaten up, add a fourth of a teaspoonful of mustard, a little less red pepper, already ground, and a teaspoonful of nice butter. Stir this mixture all the time. Then add, lastly, a few crackers well broken up, and after thoroughly incorporating them into the mixture, turn it all into a heated dish and cover it.

English Salad Sauce. — Pound in a mortar the hard-boiled yolk of an egg; mix with it a salt-spoonful of salt, a teaspoonful of mustard flour, a mashed mealy potato, two dessert-spoonfuls each of cream and olive oil, and a tablespoonful of good vinegar.

Carpeted Floors. — When a carpet is taken up to be cleaned, the floor beneath it is generally very much covered with dust. This dust is very fine and dry, and poisonous to the lungs. Before removing it, sprinkle the floor with very dilute carbolic acid, to kill any poisonous germs that may be present, and to thoroughly disinfect the floor and render it sweet.

The Arts.

NICKEL, AND NICKEL PLATING.

Nickel, although known for more than a hundred years, has been brought prominently before the public only within a very few years. Its alloys with copper and brass have been long used, but no one seems to have thought of applying the metal to any useful purpose until about the year 1866, when patents were issued to Messrs. Adams and Remington for methods of depositing nickel from solution. Whether either of these gentlemen had any claim to priority of invention is now a question before the courts, and it is so loaded down with technicalities that it seems likely to stay there for some time. In the meanwhile several firms in Boston are actively engaged in the nickel plating business. They find a ready demand for all the work they can do.

Nickel, when pure, is of a silvery whiteness; it admits of a high degree of polish, and is not so readily scratched or tarnished as silver. It has a degree of hardness almost equal to steel. For the purposes of protecting nice mathematical and astronomical instruments from oxidation, nothing has yet been discovered that will equal it. Under conditions when silver will soon become tarnished, nickel preserves its polish for years. It is therefore extensively used for the graduated parts of instruments. It has, however, been found that the graduation must be done before the instruments are plated, as the nickel forms a hard surface, so that it is almost impossible to cut it. Delicate instruments coated with it look nice and clean, and have the advantage over the brass, that they are not attacked by mercury which may accidently fall upon them.

Nickel forms a perfect protection for steel articles; these are first coated with a thin film of copper by electrolysis, and then receive a heavy coating of nickel. In fact there is hardly a tool or implement upon which nickel may not be used, if a bright metal surface is desired.

In order to deposit nickel, a solution of the sulphate of nickel and ammonia is used in connection with anodes of cast nickel. Dr. Adams has separate patents on the solution and on the anode. Any one who wishes to see the metal can readily throw down a small portion in the following manner, which is not patented.

If pure nickel cannot be obtained, dissolve nickel coins (which contain about twenty-five per cent. nickel) in sulphuric acid with the addition of a little nitric acid, then evaporate to dryness, or nearly so, to expel all the nitric acid and any excess of sulphuric acid.

Dissolve the salt in water, adding if necessary a few drops of sulphuric acid, taking care to avoid any great excess of water, as it is best to keep the solution as concentrated as possible. Place in the liquid two plates of platinum which are connected with two cells of a Grove or Bunsen battery, or three cells of a Daniels' battery coupled for intensity. By this means we can completely remove the copper from the solution in the course of a few hours. When the copper is completely removed, which can readily be determined by testing the solution with a little hydrosulphuric acid, the plate upon which the copper is deposited is removed, the solution is made strongly alkaline with ammonia, and the article upon which it is desired to deposit the nickel is suspended in place of the copper-co ered plate. It will generally be found necessa to add another cell to the battery in order obtain a sufficiently powerful current to depo the nickel. The process as given above is excellent one for the separation and quantitati estimation of copper and nickel; the plate platinum being weighed before and after the de osition of the copper, it is then replaced in t solution and the nickel is deposited directly up the copper. The mass is again weighed, the la increase of weight being of course due to t nickel.

This process for the estimation of copper an nickel is due to Dr. Gibbs, who first publish it in the *American Journal of Science*, v. xxxix., January, 1865.

MEMORANDA IN THE ARTS.

Waterproof Starch. — A patent has be taken out in France for the preparation of a fini, or starch, for vegetable tissues, yarns, clothes, et, which is not soluble in water, and which, therefo, when once applied, will remain throughout seve successive washings. In this case, the articles i question are properly starched, and then passed a temperature of about sixty degrees Fahrenh through a bath of chloride of zinc, by means which such a change is produced in the fibre a the starch that the latter resists the action of water in the most thorough manner. A bath three parts of sulphuric acid and one of water m, it is said, be used instead of that of chloride zinc. The liquid is to be placed in a trough, which a revolving barrel is immersed, almost its axis, and above which is a roller which is mov in an opposite direction by the turning of the low one. Between the two the material to be impr nated is passed, being moistened from below the bath, and receiving during its passage necessary pressure. If the material be heavy, barrel lies entirely in the bath, and a pair of roll fixed above it is used to press out the superflu liquid. The articles are carried directly from trough into running water, from which they are be removed, pressed out, and dried.

German Soup Tablets. — The following Reinsch's receipt for making the soup tablets wh were extensively used by the German armies the late war; Take eleven parts by weight of g suet, melt it in an iron pan, and make it very h, so as to become brown; add, while keeping the stirred, eighteen parts of rye meal, and conti heating and stirring so as to make the mass brow; then add four parts of dried salt and two parts coarsely pulverized caraway seed. The mixt is then poured into tin pans somewhat like th used for making chocolate into cakes. The ca have the appearance of chocolate, and are chi intended for the use of soldiers while in the fi. A quantity of about one ounce of this preparat is sufficient to yield, when boiled with some wat, a ration of good soup, and in case of need, cakes, being agreeable to the taste, may be ea raw.

A Revolving Safe. — Among the articles hibited in the industrial department of the Lond International Exhibition just concluded, is sor thing new in the shape of a revolving safe. It made in a circular shape, and when locked a placed in a position either against a wall, or b into it, the door is turned into the wall, the ba facing the spectator. To open the safe, a lock opened in a strong iron box on which the safe res. This moves a spring, which enables the operat, by means of a small hand key, to bring the door the safe round to the front, and causes a bell ring a loud alarm. The door being opened

means of a key, another door presents itself, which is opened by being moved round to the back of the safe. The invention has been much admired.

Tungstic Glue. — Tungstic glue bids fair to become a substitute for hard india rubber, now so high in price. It is prepared by mixing a thick solution of glue with tungstate of soda and hydrochloric acid, by means of which a compound of tungstic acid and glue is precipitated, which at a temperature of 86° to 104° Fahrenheit is sufficiently elastic to admit of being drawn out into very thin sheets. On cooling, this mass becomes solid and brittle, and on being heated is again soft and plastic. This compound, it is said, can be used for all purposes to which hard rubber is adapted.

Purification of Fats. — The *Comptes Rendus* gives an account of a process communicated to the French Academy by M. Boillet. Suet, or fat of any kind, is heated for three or four hours with lime water, the proportions being about half a gallon of lime water to 2½ lbs. of fat; it is then allowed to cool. As soon as the fat is sufficiently set, it is transferred to a linen or flannel bag, and the water and oleic acid squeezed from it by gradually increasing pressure, in a hydraulic press, or otherwise. He states that fatty matters thus treated lose all bad smell, and acquire remarkable whiteness and hardness, after standing a few days. If re-melted in water, acidulated with sulphuric acid, acetic acid, or vinegar, a fat is obtained which is "perfectly" purified, and can be applied to all purposes for which the best fats are employed.

PRACTICAL RECIPES.

Black Lustre. — Dr. Kielmeyer gives a recipe which is adapted for either paper, cloth, or porous wood. It stands well, is very supple, and has no tendency to get sticky. To prepare it, boil together 8 pounds of glue, previously dissolved in 16 pounds of water; 1 pound of potato starch, dissolved in 5½ pounds of water; 5¼ pounds of campeachy, extract of 6° Beaumé; 1 pound 2 ounces of green vitriol, and 8¾ pounds of brown glycerine. When thoroughly mixed, remove the pot from the fire, and continue to stir until the liquid is cold. If the paint be desired thicker or thinner, the amount of starch and glue must be varied, as well as the other materials.

To Give Plaster of Paris the Appearance of Marble. — Put into four pounds of clear water one ounce of pure curd soap, grated and dissolved in a well glazed earthen vessel; then add one ounce of white beeswax cut into thin slices; as soon as the whole is incorporated, it is fit for use. Having well dried the figure before the fire, suspend it by a twine, and dip it once into the varnish; upon taking it out, the moisture will appear to have been absorbed; in about two minutes' time stir the mixture and dip it again, and this generally suffices. Cover it carefully from the dust for a week, then with a fine soft muslin rag, or cotton wool, rub the figure gently, and a brilliant gloss will be produced.

Or, take well skimmed milk, and with a camel's-hair pencil apply it to the model until it holds out, or will imbibe no more. Shake off or blow off any that remains on the surface, and lay it in a place perfectly free from dust. When dry it will look like polished marble. This mode answers well, if the figure is not to be exposed to wet weather.

To Remove a Screw from Wood. — Heat a piece of iron red hot, and put it on the top of the screw for a minute or two; then the screwdriver will easily get it out, if used while it is warm.

A New Brass Solder. — A new brass has been devised, having its expansion and contraction by changes of temperature the same as those of iron or steel; or so nearly so, that it may be used to solder those metals to brass. Its composition is: tin, 3 parts; copper, 39½ parts; zinc, 7½ parts.

Agriculture.

FARM PENCILLINGS AT LAKESIDE.

CORN FODDER.

The opinion we have always held upon the question of the value of green corn fodder for milch cows has been, that when raised from broadcast sowing it is nearly worthless, but when sown in hills or in drills, and cultivated, with access of air and sunlight, it is of high value. During the present season we have made some experiments to test the correctness of these views. Stalks were collected from a field where the seed was sown broadcast, and also stalks growing in drills upon the same field, and they were dried in a drying closet to expel the moisture. Both specimens were planted at the same time (the 6th of May), and it was found that the plants from the broadcast sowing contained 92 per cent. of water, those from drills 83 per cent. of water. Thus it was shown that the difference of solid matter in the two was relatively as 8 to 17 per cent. The solid matter was composed of starch, gum, sugar, and woody fibre. There was almost an entire absence of sugar and gum in the stalks from the broadcast sowing, while the stalks that had grown under the influence of light and air held these nutrient principles in considerable quantities. The stalks were collected at the period of growth just before the ear begins to form, a period when most farmers commence to cut the fodder for their cows. Our experiments upon corn fodder have afforded us important information upon other points. We find that the stalks cut before they reach a certain stage of growth are deficient in nutrient matter, and therefore it is a waste to feed them too early. The corn plant, like all other vegetable structures, has but one object or aim in its growth, and that is to produce seed. It is engaged during its whole life in storing up large quantities of starch, which is to be used when the pressing occasion arrives, or the seed vessels mature, to form by some subtle mysterious changes the rich nutrient principles which are found in seeds. As soon as this struggle is over, the corn plant, like all animals, dies a natural death. It is not necessary for frost to strike it; it dies from simple exhaustion. The proper time to cut and feed corn stalks is during the four or five weeks which succeed inflorescence, or in other words they should not be cut until the flower is fairly developed, and the ear commences to form; and any corn that is so planted that the ear cannot form and *mature* is *practically worthless as fodder*. Farmers may learn from these facts that corn designed to be cut for fodder should be planted at two or three periods during the season; some fields quite early, others somewhat later, and still others as late as is safe. In this way, when the hot, dry months of July and August are reached, and the pastures falter, a supply of fodder is secured, at a proper stage of growth to afford the largest amount of nutriment. Our note-book contains many *pencillings*, recording the results of experiments with corn fodder, which we will present hereafter.

POTATOES.

We all have observed the great deterioration in our potato crops, during the past ten or twenty years; and what is the cause of this alarming decrease of tubers? Can science, can chemistry point out the reason, or aid in remedying the difficulty? We think it can, and in order to place the matter in a clear light we will point out the kind and amount of food which the potato demands. We had a field of potatoes upon the farm which yielded 300 bushels to the acre; this may be regarded as an old-fashioned crop. This crop removed from the soil in tubers and tops at least 400 pounds of potash; also it removed 150 pounds of phosphoric acid. Now these amounts are very large, and serve to show that the potato plant is a great consumer of the two substances, and also it shows that in order to restore our potato fields to their former productive condition, we must supply phosphatic compounds and substances holding potash in large quantities. For six or eight generations in New England, our fathers have been exhausting the soil, by removing these agents in their potato and other crops, and we have reached a time when the vegetable is starving in our fields for want of its proper food. Our farmers have found that new land gives the best crops, and this is due to the fact that such fields afford the most potash. But so long as we crop our pastures so unreasonably, we cannot resort to new land, as land is not *new* that has had its potash and phosphatic elements removed by grazing animals. Remember that a potato field which gives but 100 bushels to the acre requires at least 160 pounds of potash, but by allowing the tops to decay upon the field, 60 pounds of this is restored to the soil again, as that amount is contained in them; a medium crop of potatoes requires twice as much phosphoric acid as a medium crop of wheat, so that in two years with wheat the land is deprived of no more of the agent than it loses in one year with potatoes.

NEW SOURCES FOR SUPPLIES OF POTASH.

There has never been a time when soil cultivation as a pursuit was more hopeful and promising than the present. We have just learned the important fact that an abundance of plant food has been stored up for our use in mines and rocks, and that we have only to reach out our hands and take all that we require. Ten years ago who could even have dreamed of such vast deposits of potash as have been opened up to us at the Stassfurth salt works in Germany. Some idea of the supply may be formed from the fact that at the present time more potash is furnished from these mines than from the wood ash sources of the whole world. About 13,000 tons of potash were sent to market from the United States and British America in 1870, and yet at Stassfurth, where a dozen years ago it was not supposed that a single ton could be procured, 30,000 tons of the muriate of potash were manufactured and supplied to consumers upon both continents during the past year. The surface salts at these mines, which hold the potash, are practically inexhaustible, and millions of tons will be supplied in succeeding years. No doubt our own salt mines will be found upon careful examination to afford potash, and hence we may look with confidence to the rapid cheapening of this most useful product.

GRAPES.

The vineyard at Lakeside has produced bountifully the present season. The Concords and

Delawares ripened perfectly, and the fruit was of superior quality. This vineyard has never received any dressing since it was planted, six years ago. It then received a generous supply of fine ground bone and unleached ashes, and these have supplied all the food required. No animal excrement has been used in connection with the vines, and the results have been highly satisfactory. Potash and phosphoric acid are the two agents most largely consumed by grapes (as mineral food), and these must be supplied to insure successful crops.

SORREL AS A POTASH PLANT.

Under the above head there appear some rather remarkable chemical statements in the *Vermont Farmer* for Sept. 30, 1871. The following passage is particularly worthy of notice:

"By means of that very oxalic acid which sorrel takes from the atmosphere, it acts upon the solid feldspar sand which surrounds its roots, and dissolves out enough potash to supply its wants."

If this is so, we have been working upon wrong theories, and incurring useless expense in supplying potash to soils that contained feldspar. It would be better to raise a crop or two of sorrel and plough it under, in order that the oxalic acid of the sorrel may be able to act on feldspar more extensively. But manifestly some wrong views are entertained regarding the matter. In the first place, no plant has power to prepare its own food, but must take such as is present in the soil in a soluble form; and second, if the experiment is tried of dissolving feldspar in oxalic acid, it will be found to be a difficult operation, as the mineral is totally insoluble in this acid.

AN ABSURD IDEA.

Colonel Pleasanton, of Philadelphia, it is stated, claims to accomplish wonders in vegetable and animal growths by the use of violet or blue glass. He remarks very truly that the violet are the chemical rays; but he overlooks the important fact that by using violet colored glass, he diminishes the very rays that he proposes to increase. No means are known to science by which we can increase the intensity of light in any portion of the spectrum. We cannot change red light into violet or violet into red; the only change we can make is to cut off a portion of the rays, but in so doing we diminish the intensity of all the remaining ones, to a greater or less amount. The only effect of the violet glass would be to cut off the yellow, orange, red, and green rays, without adding anything to the violet; in fact the violet would rather be diminished.

NITROGENIZED COMPOSTS.

We find in *The Plantation* an account of some experiments made by M. Bortier, an eminent Belgium agriculturist, on the artificial production of saltpetre in composts, from which we make the following extract:—

A large quantity of stable manure was spread in a farmyard, under rough covering. It was divided into three equal parts. The first part was left, in the usual way, to be trampled by stock. The second was secluded from the stock and spread lightly. The third part was spread lightly with alternate layers of marl, the marl being about three per cent. in weight of the part of manure. This process went on from early spring to September, when these three portions of manure were applied to a piece of land divided into three equal parts, being of the same quality of loamy soil.

For four crops in succession (with only one application of manure) that part containing marl produced over ten per cent. more than each of the other parcels, by careful measurement.

M. Bortier had a portion of marl from his compost analyzed by a competent chemist, when the formation of nitre was fully proved.

From further experiment it is inferred that the capacity for absorbing nitrogen from the atmosphere varies with the kind of lime used. The most porous kinds (calcareous tufa, for instance) absorb nitrogen most rapidly. And, moreover, the addition of a small quantity of lime, already nitrogenized, increases considerably the capacity of the mass for absorbing nitrogen and producing saltpetre.

This is illustrated in the following experiment: One thousand parts of marl, placed in layers among stable manure for two months, produced by analysis 0.69 parts of nitric acid.

One thousand parts of marl, treated in the same way, but previously mixed with 50 parts old plaster and mortar, containing 0.62 parts of nitric acid, were found, after two months, to contain 2.3 parts of nitric acid. Subtracting the .62 added with the plaster, the acid produced by this experiment was 1.68, or nearly three times that produced by the first experiment.

It is the opinion of M. Bortier, that the particles of limestone thus nitrogenized will continue for years to absorb nitrogen from the atmosphere and fertilize the soil with which they have been mixed.

PRESERVATION OF EGGS.

The subject of the preservation of eggs has recently attracted a great deal of attention, and many methods of effecting it have been published, though none are altogether perfect for the simple reason that the true cause of the spoiling of the eggs is either unknown by those who have attempted to furnish us with directions, or has been lost sight of by them. There are two efficient causes for the spoiling of eggs, and unless one or both of these are avoided, we cannot hope for success. The first is exposure to a high temperature, and the other is access of air. It may be safely affirmed that, at temperatures below 32 deg. Fah., nearly all change ceases in organic bodies, while very few organic substances will bear continual exposure to a temperature above 90 deg. The freezing point is rather too low for the preservation of eggs in good condition, as freezing affects the flavor unfavorably; but if we desire to preserve eggs in the best manner we must keep them cool—say at a temperature below 50 deg. if possible, a temperature which is frequently maintained in good cellars. But it will be of no use to place the eggs in a cool cellar if they have been previously exposed for hours to a temperature of over 90 deg.

The collection of the eggs must, therefore, in the first place, engage our attention. Those who raise poultry, and especially those who keep fowls for the sake of their eggs, commit a great error when they fail to remove from their yards those birds that are inclined to set, and which consequently take every opportunity of warming the eggs in the nests. If any one will attempt to preserve eggs that have been subjected to the hatching process for one or two days, he will discover the force of this statement.

Kohler, of Germany, who owns an extensive poultry-raising establishment, and who, every winter, preserves thousands of eggs without ever losing one, has recently published an account of his method of proceeding, and has given the following rules fo[r] securing favorable results:—

1. The nest must be placed in a cool position.
2. The fowls that show a tendency to set mus[t] be removed at once, and placed in separate inclos[]ures until this propensity has left them.
3. If many hens be confined in the same inclosure or use the same nests for laying their eggs, the egg[s] ought to be removed from the nests several times [a] day.
4. The eggs ought to be assorted according t[o] age, and preserved in boxes with the covers alway[s] partially open. These boxes must be kept in a cool airy, and perfectly dry place.
5. At the commencement of winter, the store o[f] eggs is placed in some room that is not heated by [a] fire, but that is, at the same time, thoroughly pro[]tected from frost.
6. The packages are so arranged that the oldes[t] may be used first.

Eggs treated according to these rules do not ac[]quire the peculiar taste which is generally the resul[t] of the receipts in vogue for preserving eggs.

HINTS FOR THE FARM.

Watering Teams Often.—Horses and oxe[n] at work need water often. The ploughman carrie[s] his jug of water, or leaves his team to rest whil[e] he goes to the house for a drink. But the tean[m] works harder than the driver, and probably need[s] drink as often; yet many teams are taken out earl[y] to the field, where there is no water except in th[e] driver's jug, and work five or six hours before the[y] can get a drop. Is it any wonder that they ar[e] injured by drinking too much when they are le[d] to the spring at noon or evening?

To Keep Flies from Horses.—One of th[e] simplest means of keeping flies from annoying horses or cattle, is to take a bunch of smart-weed, bruise it so as to make the juice exude, and ru[b] the animal thoroughly with this bunch of bruised weed—especially upon his neck, legs, and ears Neither flies nor other insects will trouble him for at least twenty-four hours. If preferred, an infu[]sion may be made by steeping the weed, and the liquid applied with a sponge.

Hens versus Dogs.—The *Poultry Standard* has the following sensible remarks on this subject: "There is hardly a family that does not throw away enough table scraps to keep at least half a dozen hens; and many that keep a nuisance in the shape of a dog, that does no good, but costs more than a dozen good hens, complain that they cannot afford to keep hens. One dog in a neighborhood is greater trouble to the neighbors than a flock of hens would be, for if hens are well fed at home they will rarely go away. But who ever saw a dog that was not a pest, running across the newly-made garden, and sticking his nose into everything? Kill off the curs and give the food to the hens, and you will find pleasure as well as profit in so doing. We wish there was a tax of one hundred dollars on every dog kept in the country. Those that are of value as watch dogs could be retained, while the host of snarling, dirty curs would give place to some more useful and less troublesome pet."

To Make Common Hard Soap.—Put into an iron kettle five pounds unslacked lime, five pounds soda, and three gallons of soft water; let it soak over night; in the morning pour off the water, then add three and a half pounds of grease, boil till thick, turn into a pan until cool, and then cut in bars.

To Dry Pumpkins.—Peel and cut as for cooking; then slice them very thin, spread on tin or other driers, and expose to a moderate heat in the stove oven. Thus dried, the pumpkin will retain its natural flavor. To prepare it for cooking, soak it in water a few hours.

SEEDS AND CUTTINGS.

Mr. Dickens on Farming. — The younger Charles Dickens, in a recent number of *All the Year Round*, says: "The part of the holding of a farmer or land-owner which pays best for cultivation is the small estate within the ring fence of his skull. Let him begin with the right tillage of his brains, and it shall be well with his grains, roots, herbage and forage, sheep and cattle; they shall thrive, and he shall thrive. 'Practice with science,' is now the adopted motto of the Royal Agricultural Society."

Farming in Japan. — The Hon. James Brooks writes from Japan: "Proud as I am of the arts, sciences, and marvellous doings of my own country, I blush when I compare American farming with this. Here are the rice fields artificially created, luxuriant in beauty now, terraced from hill-side, up and down, and watered by the hill streams, or not watered, as the husbandman wills. There are barley fields and bean fields, and fields of all sorts of Japan agricultural productions. Forests cap all the hill-tops. Two crops are raised in Japan in one year, even on the rice fields, where the first crop is grain. The grain harvest is over in April or May. The rains come on in June or July, and now the new crops are up, and the whole is one beautiful landscape of green."

Science in Agriculture. — A writer in the *Western Rural* makes the following sensible remarks: "The sooner we throw away the words science of Agriculture, and substitute Science in agriculture, the sooner we shall be on the high-road to scientific farming. It rests upon all science, taking only a portion here and there, just as the animal crops the herbage as he passes along. He can live and even grow fat upon but few varieties, but for his full sustenance craves many. So of the farmer. He can get along better than any other profession with but little knowledge except that of mere art. The moment he reaches after that higher knowledge, it should be in such directions as will enable him to profit by it. 'The principles of science, and not the bare manipulations of art,' is what he should attain, but, as a practical man, science, only so far as it may bear upon, or can be applied to his practical art."

Soot for Rose-bushes. — A correspondent of the *New York Observer* says: "Never give up a choice but decaying rose-bush till you have tried watering it two or three times with soot tea. Take soot from a chimney or stove in which wood is burned, and make tea of it. When cold, water the rose-bush with it. When all is used, pour boiling water a second time on the soot. The shrub will quickly send out thrifty shoots, the leaves become large and thick, and the blossoms will be larger and more richly tinted. To keep the plants clear of insects syringe them with quassia tea. Quassia chips can be obtained of the apothecaries."

Valuable Information for Farmers. — We find the following among the "Answers to Inquiries," in a Western agricultural journal: —

"A Pound to a Quart. — *A. C. I., Brooklyn, Iowa.* — The experience of cheese factories is that a quart of milk will produce a pound of cheese almost invariably. You can, therefore, safely make calculations upon this basis."

We fear that "A. C. I." is doomed to disappointment, if his prospective profits in cheese-making are calculated upon the "basis" here given. If he can accomplish the miracle of converting water into cheese, he may be more successful with milk containing 88 per cent. of that liquid than we have led him to expect; but otherwise, he had better reckon at least six or seven quarts of milk to the pound of cheese. Our former estimate of *ten* quarts refers, not to green, but to *old* cheese.

Boston Journal of Chemistry.

Jas. R. Nichols, M. D., *Editor.*
Wm. J. Rolfe, A. M., *Associate Editor.*

BOSTON, NOVEMBER 1, 1871.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

Mr. A. D. Blanchard *is no longer a Travelling Agent for the Journal. All money paid on Journal account should be sent directly to the office, 150 Congress Street.*

CHEMICAL ANALYSIS.

J. R. NICHOLS & CO., Manufacturing and Analytical Chemists, 150 Congress Street, Boston, will give special attention to chemical investigations of every kind. They will make accurate analysis of Ores, Minerals, Gold, Silver, Copper, Lead, etc. Also of Drugs, Dyes, Chemical Substances, Soda Ash, Indigo, White Lead, Oils, Paints, Wines and Spirituous Liquors, Madder, Opium, and all commercial articles.

Special attention given to Spring, River, or Well Waters suspected to contain Lead, Zinc, or other deleterious metals. The quantity of water required for qualitative analysis is half a gallon, and when sent by express all express charges must be paid or it cannot be received. The charge for qualitative analysis of Water for the detection of Lead, Zinc, or other single impurity, will be Five Dollars. Charges for other work in all cases moderate.

Parties in any section of the United States desiring our services will please in their correspondence state the nature of the work required, and instructions will be given regarding the securing and forwarding of specimens, and also advices regarding the probable cost.

THE SUN.

Not only explosions of steam boilers, gun cotton, nitro-glycerine, gases, etc., are occurring constantly in all parts of our little planet, but the sun has recently shown us what can be done in the way of an explosion upon a grand scale. The paper which Prof. Young, the distinguished Dartmouth astronomer, communicates to this number of the Journal, will be read with deep interest by every one. It is certainly an important contribution to our knowledge of solar physics, and will add to the author's reputation as being one of the most vigilant and competent observers living. No statement could afford a clearer idea of the stupendous energies and intense activities prevailing on the sun than that of Prof. Young, and the phenomenon must have a near or remote bearing, not only upon our planet, but upon the whole family of bodies which are held in place by the sun's attraction. The change in the spectrum after the "in-rush" of luminous matter which followed the explosion, is a most interesting and important point, inasmuch as it would seem to show that new elements or forms of matter were brought to the surface by the disturbance. Prof. Young observes that during the unusual brilliance and excitement of the solar surface, on the afternoon of the 7th of September, *fifteen or twenty new lines* were observed in the spectrum. Explosions of this kind are probably not infrequent, and it is singular that no one has yet been brought directly under telescopic observation. The thirty minutes' absence of Prof. Young from his instrument happened to be a most important period of time, and no one can regret the circumstance more than himself. Our interest in solar spectroscopy increases every year, and we have reason to expect that the enlargement of the boundaries of knowledge in that direction will be rapid and wonderful. The cuts which accompany the paper are from pen and ink sketches, supplied by the author.

THE PERILS OF NAPHTHA.

It is stated that the unparalleled conflagration at Chicago originated from the breaking of a kerosene lamp, and as it is impossible for true kerosene of legal standard to form ignitable vapors at ordinary temperatures, it is evident that the liquid which caused this immense amount of human misery was inflammable *naphtha*, one of the most dangerous agents with which we have to contend. It may be necessary that millions of property should be destroyed in order to awaken the community to a sense of the perils of this incendiary liquid, which is introduced into dwellings as a source of artificial illumination. We have during the past six years devoted column after column in this journal to exposing the frauds and tricks of travelling mountebanks, and unprincipled dealers in our towns and cities, who are selling naphtha as kerosene, or under some assumed and taking name. It is an *immense evil*, which should receive the immediate attention of officers of the law, and of every humane citizen.

Every autumn, pedlers start out from cities all over the country, and sell naphtha *as a safe oil*, or sell to unsuspecting people recipes for making an *inexplosive oil*, the chief ingredient of which is naphtha. They give to it new names, *solar oil*, or *sunlight oil*, or *crystal liquid*, or *lunar oil*, or some other high sounding title to deceive the uninformed and unsuspicious rural population. These men ought to receive similar treatment to that which befel the incendiaries who were detected in their infernal work at Chicago. It is very strange that sensible people can be so deceived, but the appeal is to the pocket. Naphtha costs but a trifle, and the difference of a few cents in the cost of a gallon of burning fluid weighs largely with many. We hope no reader of the Journal can be deceived by the makers of "*safe oils*." Housekeepers had better introduce gunpowder or robbers into their dwellings, than any one of the "inexplosive" oils or fluids which are sold throughout the country. If you need a safe illuminating oil, go to a respectable dealer, and purchase "kerosene" of legal standard; and in order to be assured that it is safe, insist upon having a competent inspector appointed in your town or village, and have him test all burning liquids according to the plan we have described in the Journal.

HIRAM POWERS.

The friends of this distinguished American sculptor have known that he has been engaged upon a statue for many months which he designed to be his greatest work. In a letter which we have just received from Mr. Powers, he remarks as follows: "The 'Eve,' or as I

prefer to call it, 'Paradise Lost,' is now quite finished, or will be soon, as there is nothing but some slight touches about the base and the tree support to complete it. You will notice in the photograph of the figure which I send, that the head of the serpent was not quite finished when it was taken. He is represented as descending the tree stump, and Eve is accusing him with her right hand: 'The serpent tempted me, and I did eat.' The figure is six feet three inches high, but does not seem so tall, unless contrasted with some person near it. The marble is very beautiful, and I am certain I have done nothing superior to this, and all my visitors think so." It is probable that this magnificent work of art will adorn the new mansion recently completed by Mr. A. T. Stewart, of New York.

Mr. Powers's health has been much impaired from constant labor, and he was obliged to leave Florence in the spring, and visit England, where he has remained until the last month. During the five months before leaving Italy, he modelled no less than *eleven* portrait busts, mostly of Americans. Mr. Powers is now quite advanced in life, and from the photograph of himself which he was so kind as to send us, we perceive that he has changed greatly during the decade of years since we saw him at Florence. He is an artist of whom every American is proud, and we hope he will live many years to enjoy the fruits of his labors.

FLOATING STEAM FIRE-ENGINES.

The great fire in Chicago has been the means of drawing public attention to the risk of similar disasters in other of our large cities, and to the means of averting the danger. It is generally admitted that, with our present modes of building, this risk is a very serious one; and since our cities could not at once be reconstructed on better principles, even if we were ready for the architectural reform, the immediate question must be, how to increase the safeguards against fire, and the appliances for checking its ravages. Among the latter, it seems to us that floating fire-engines deserve mention, though, so far as we are aware, they are almost unknown in this country. Two years ago we had an opportunity of examining one of them in London, where they have proved of great service in checking the spread of conflagrations occurring near the banks of the Thames. They have two engines, of about twenty-five horse power each, so arranged that they can be used either for propelling the boat or for throwing water upon a fire. Steam is always kept up in one of the boilers, and the other is ready for having its fires started at a moment's notice. On an alarm of fire, the boat is under way at once, and by the time it reaches the spot the second engine is steamed up. The two can throw ten tons of water a minute, and often with force enough to knock down the walls of a building after the timber work within has been partially burned out. The management of the stream is in the hands of regular firemen on land; the crew of the floating engine attending exclusively to the work on board. The equipment of hose is very large, and serves to make the engine useful at considerable distance from the river-bank.

The motive power of these craft is neither paddle-wheels nor screw. Paddle boxes would be an obstacle to rapid movements in narrow and crowded docks, and even a screw would often be in danger of getting "fouled" in such peculiar navigation. The form of propulsion adopted is simple and in keeping with the regular business of the engines. It consists merely in forcing two streams of water from the stern of the boat against the water of the river. The engine thus "squirts" at the *water* until it reaches the place where it can "squirt" at the *fire*; when the pipes at the stern are closed, and those to which the hose is attached are opened. It will be seen that this arrangement obviates the necessity of complicated machinery for propelling the vessel, distinct from that required for its uses as a fire-engine; and that the risk of its getting out of order is proportionally less.

Engines like these can often work in situations where the ordinary steam fire-engines cannot get a fair chance to work, especially in conflagrations among shipping, and among wharves and docks. It is, moreover, easy to imagine cases in which, from the fact of their being afloat, they could continue to pour water upon a fire after the land engines had been driven "out of range" by the heat, or had been cut off from a supply of water. In fact, their advantages as a branch of the fire department in any city or large town situated on ocean, lake, or river, are so obvious that we need not enlarge upon the subject.

EDITORIAL NOTES.

Dr. Liebreich of Berlin. — We have information that Dr. Liebreich is desirous of coming to this country, with the view of making it his home. Such a man would be an acquisition to any country, and we hope that measures will be taken to secure his services in some one of our colleges or medical schools. The man who, by a course of inductive reasoning, was able to point out the hypnotic powers of chloral, and establish the agent as one of the most important in materia medica, is entitled to the highest honors, if he had no other claims to distinction. Dr. Liebreich is one of the most remarkable men of the age, and in research and analytical skill has few equals. He is not only a physician, but a chemist and physicist, and the boundaries of knowledge in many departments have been greatly extended through his labors. It will be fortunate for our country if we can add his name to our list of scientific investigators.

The Journal in England. — We have some enthusiastic patrons and friends in England, who often send us complimentary and encouraging letters. A distinguished English gentleman writes as follows, from London: "I think highly of the Boston Journal of Chemistry, and in spite of my numerous and pressing duties, I always find time to read it. It really keeps us informed with regard to what is transpiring in the world of art and science on both sides of the water."

Complimentary. — On the 13th of October, Prof. Young, of Dartmouth, received a cable telegram from Prof. Lockyer, the eminent English astronomer, inviting him to join the English Eclipse Expedition to India, offering to pay all expenses, etc. This is a high compliment, and it is a matter of regret that the important home duties of Prof. Young prevent him from accepting the invitation.

Lectures and Lecturers. — We are greatly obliged to our numerous friends in various parts of the country, who send pressing invitations for us to lecture before lyceums, literary and scientific associations, etc. However much we may desire to gratify our friends, our duties are so numerous and pressing, that we have but little time to devote to lecturing. The deep interest we take in the progress of agriculture, has led us to address agricultural meetings and associations, and this we are willing to do occasionally, when circumstances will permit; but the general lecture-field we cannot enter. We earnestly hope that in arranging courses of lectures in the various cities and towns of the country, the ensuing winter, sensational lecturers will be avoided, and something more useful and healthful will be provided. There are lecturers who combine entertainment with instruction, and they should be widely known. Prof. E. S. Morse, of Salem, Mass., presents topics of Natural History in a delightful manner, and every association should secure, if possible, one or more of his lectures. His subjects are, "How Animals Move," "How Animals Feed," "How Animals See," etc., etc., and with marvellous skill in the use of the black-board, he makes everything plain and easily understood. Prof. Niles, of Cambridge, is an easy and graceful lecturer upon geology and kindred topics, and there are others, less known, who ought to be encouraged.

Enamelled Water-Pipes. — Our attention has been called to some specimens of enamelled iron-pipe for water conduction, which have recently been manufactured in England. So far as we can judge, it appears to meet a most important want, and if the vitreous coating which is upon the inner and outer surfaces is stable, — and we think it is, — it leaves nothing further to be desired in the way of a safe and cleanly water-pipe. The turns and couplings are enamelled, and thus water contact and consequent oxidation is prevented through the entire extent of the supply pipe. The expense will not, we trust, prove a bar to its general employment.

Chemical Experiments. — Most persons have an idea that it requires a great deal of expensive apparatus to show chemical experiments. Such is, however, not the case; a great many pleasing and instructive experiments can be shown without any more apparatus than can generally be found in any dwelling. And with the addition of a few glass tubes of various diameters, a dozen or two test tubes, a pint flask or two, and an assortment of ordinary glass bottles and corks, there is scarcely an experiment that may not be attempted with fair prospects of success. In order to make bell glasses, it is only necessary to cut the bottoms out of bottles; these may be made of various sizes at an expense that should not exceed thirty or forty cents for the one holding two quarts. In order to cut out the bottom, a mark is made with a sharp three-cornered file, about an inch from the bottom; a piece of ignited charcoal is held against this mark until the bottle cracks. With a little skill the crack may be made to follow the charcoal around the bottle. The edge is then rounded off with a file, or it may be ground off on a grindstone. With such a bell glass all experiments which do not require the use of an air pump may be shown. A dinner plate answers very well to stand it in, a little water having been previously poured into the plate. A common wooden pail answers for a pneumatic trough, a board perforated with a few holes being placed across it a short distance below the top.

New Planetoids. — Within a few months there have been three additions to the large family of minor planets between the orbits of Mars and Jupiter; and the credit of their discovery belongs to American astronomers. The first (No. 114) and the third (No. 116) were picked up by Prof. C. H. F. Peters, of Hamilton College, N. Y.; the former on the night of July 23d, and the latter on the night of Sept. 8th. No. 115 was detected by Prof. J. C. Watson, at Ann Arbor, Michigan, on the night of August 6th. No. 114 has received the name of *Cassandra*, but the names of the others have not yet been announced. Our readers are aware that the whole hundred and sixteen of these "children of the sun" have become known to astronome

uring the present century, and all but four of them within the last twenty-six years. Only one (*Vesta*) ever visible to the naked eye, and that only under favorable circumstances of position and atmosphere, while most of them are to be seen only with telescopes of considerable power. The magnitudes of the three last discovered, for instance, are given as 1.3 (though it will be somewhat brighter when it comes nearer to us), 10, and 11. The smallest stars visible to the unaided eye are of the *sixth* magnitude.

SCIENCE IN PRUSSIA. — Sir Wm. Thompson stated in his recent address before the British Association, that in Prussia every university, every polytechnic academy, every industrial school, most of the grammar schools, in a word nearly all the schools superior in rank to the elementary schools of the common people, are supplied with chemical laboratories and a collection of philosophical instruments and apparatus, access to which is most liberally granted by the directors of those schools to any person qualified for *scientific experiments.* In consequence there will scarcely be found a town exceeding 5,000 inhabitants that does not offer facilities for scientific investigations at no other cost than that of the materials wasted in the experiments. And further, professors, preceptors, and teachers of secondary schools are engaged on account of their skillfulness in teaching, but professors of universities are never engaged unless they have already proved by their own investigations that they are to be relied upon for the advancement of science.

THE FREEZING OF WATER. — Boussingault finds that by preventing the dilatation of water, it may be kept unfrozen down to —18°C. He experimented with a steel gun-barrel into which a steel ball was dropped before filling it with water. During the cold days of December 1870, the temperature fell to —12° and —18°C., and yet on shaking the tube the ball was found to move freely, showing that the water was not frozen.

THE DETECTION OF IRON AND ALUMINA IN PRESENCE OF EACH OTHER. — A trace of iron is readily detected in the presence of a large quantity of alumina, but unfortunately the converse is not true. It is extremely difficult to detect a trace of alumina in presence of considerable iron. We have however obtained good results by the following process: —

The precipitate obtained by adding ammonia to a solution containing both these metals is dissolved in dilute hydrochloric acid. To the solution thus obtained, which should be only slightly acid, solution of cyanide of potassium is added in considerable excess; it is then slightly acidified with hydrochloric acid and ammonia added to alkaline reaction. If a precipitate forms, it indicates the presence of alumina. The explanation of this process is that iron forms double cyanides with the cyanide of potassa, while alumina does not. The object of acidifying after the addition of the cyanide is to prevent any solution of the ammonia by the carbonate of potassa with which cyanide of potassium is always mixed.

THE ASCENT OF ATLAS. — A recent number of the *London Times* states that "the ridge of the great Atlas, never hitherto ascended by a European, was successfully scaled on the 16th ult. by Dr. Hooker, Mr. George Maw, and Mr. J. Ball." Finding their way, under the care of a friendly sheikh, to a village at the end of a picturesque ravine, 7,000 feet above the level of the sea, they completed their ascent from that point. "The crowning ridge, forming the watershed between the plain of Morocco on the north and the Sous valley on the south, was reached at a height of nearly 12,000 feet above the sea. The isolated points on the ridge were supposed to exceed this altitude by 400 or 500 feet." It must be observed that the "watershed" here mentioned does not divide the streams which flow to the Atlantic from those which flow eastward, and are absorbed in the Central Sahara; the valley of Sous has its direction westerly, towards the ocean, which it reaches at Agadir. So the geographical summit of Atlas has not been attained. But no doubt the point reached — the snowy ridge conspicuous from the plains of Morocco — was the conventional Atlas of the ancients — the heaven-supporting hill, the dwelling of the Western giant from whom the adjoining ocean, and the nymphs who inhabit it, and the sunset region beyond its waves dreamed of by Plato, derive their names.

HONORS TO SIR HUMPHRY DAVY. — A statue to this eminent chemist is about to be erected in Penzance, the town of his birth. A working committee was formed some time since, and a sum of £500 has been raised in subscriptions. A very eligible site has been obtained from the Town Council, immediately in front of the Market-house, and facing the main entrance of the town. The statue is to be of heroic size (about seven feet high), and is designed after Sir Thomas Lawrence's portrait, painted for the Royal Society, and now at Burlington-House, but other portraits have been also studied. Sir Humphry is represented in the well-known costume of the portrait, a light overcoat flung back, the coat within buttoned over, and waistcoat with upright collar appearing above the latter, shorts, long stockings, shoes and buckles; the head is slightly thrown back, as if inspired with the courage and enthusiasm for science which excited Coleridge's strong admiration for his friend; and the right hand rests on a safety-lamp, the product and symbol of the beneficent genius of the chemist.

It may not be generally known that Davy was a poet, though his productions in that line were not numerous. We believe it was Coleridge who said of him that, "had he not been the first chemist, he would have been the first poet of his age."

ATOMS.

SOME recent experiments at the Philadelphia High School developed the fact that when a strong solution of phosphorus in bisulphide of carbon is poured upon finely powered chlorate of potassa, resting on paper, and the mixture is exposed to air, upon the evaporation of the bisulphide of carbon, the phosphorus being left in a very finely divided state, intimately mixed with the chlorate of potassa, the mixture presently explodes spontaneously, with a loud detonation. — It is said that a few drops of coal oil, applied to parts stung by bees, wasps, or hornets, will give instant relief. — Astronomers in all parts of the world are now beginning to make arrangements for the careful observation of the next transit of Venus, which occurs in 1874. — A paper on Ancient Dentistry, presented to one of the scientific associations not long ago, showed that gold was used by the Romans for filling teeth, and for holding artificial teeth, five hundred years before the Christian era. — A span of horses forty-two years old, and still in excellent condition, are daily seen in the streets of Watertown, N. Y. — The richest borax deposits in the United States are to be found in Nevada, where the area under the control of a single company covers twenty thousand acres. — To clean a sink pipe that is clogged, take a straight poker or stick, wrap one end with a wet cloth (keeping hold of the cloth for safety), and work it up and down a few times in the pipe, like a piston. — The people of Louisiana and Mississippi, have found a new source of wealth in obtaining oil from the innumerable pelicans frequenting that portion of the Gulf coast; and quite a fleet of small vessels is now engaged in capturing them. — A new telegraph pole is made of galvanized iron tubes, shutting into one another in telescopic fashion, for convenience and economy in transportation to distant points. — Mr. A. R. Wallace, who lived for years in the East Indies, says that the popular notions of the gorgeousness of tropical vegetation are incorrect; flowers being less effective in lending color to the landscape than in temperate climates, since they are fewer in proportion to the mass of mere foliage. — Our neighbor of the *Transcript*, referring to the tall, showy plants of the *Ricinus communis*, or castor-oil bean, in the Boston Public Garden, says: "Little children of to-day, brought up under the mild regimen of pellets and powders, may gambol securely in the shadow of its umbrella-like leaves; but there are still some who would shudder in passing if they knew it to be castor-oil." — Butterflies have been found flying at sea, six hundred miles from land. — One of our exchanges remarks that "Mrs. Jones was very careful to get the 'non-explosive' kind, but the lamp blew up all the same, and she died in the old-fashioned way." — For coating fabrics and tissues with metal, such as copper, silver, and gold, the material is first to be impregnated with a solution of sulphate of copper, in ammonia, and then dried; after which the whole is immersed in a warm solution of grape sugar, which develops oxide of copper, upon which silver or gold can be electroplated in the usual way — The active principles of many plants are found to be more concentrated under the slower growth of cold regions, where the vegetation is less luxuriant than in warm climates; thus tobacco grown at the North is stronger than that raised at the South, and the same is said to be true of celery. — A concise list of "infallible remedies" is given as follows: — "For corns, easy shoes; for bile, exercise; for rheumatism, new flannel and patience; for gout, toast and water; and for the toothache, a dentist." — Among the rules given in the sixteenth century for an apothecary's life and conduct, the following deserves preservation: "That he put not in *quid pro quo* (that is, use one ingredient in place of another when dispensing a physician's prescription), *without advisement.*" — "Keep the doors of the hospital closed, and the windows open," was the wise and pithy admonition of Florence Nightingale. — The Cotton-growers and Manufacturers' Association of California, has two thousand acres in cotton.

LITERARY NOTES.

THE Appletons have just reprinted the *tenth* edition of *Combe's Management of Infancy*, revised and edited by Sir James Clark, Physician-in-Ordinary to the Queen. The work is too well known to require an extended notice, and in this improved form will be more popular than ever.

In December, 1831, the *Beagle*, under the command of Captain Fitzroy, sailed from England for a survey of South America, and the circumnavigation of the globe, and Charles Darwin, then only twenty-two years old, volunteered to go as the naturalist of the expedition. After his return, in October, 1836, he published his *Naturalist's Voyage Round the World*, a work which at once gave him literary no less than scientific fame. A revised edition was published in 1845, and another in 1860. A fourth has now been called for in England, and the Appletons have republished it in uniform style with their issue of the author's recent works.

Parturition without Pain is the title of an essay by Dr. Holbrook, editor of the *Journal of Health*, published by Messrs. Wood & Holbrook, of New York, and containing a good deal of sensible hygienic advice.

First Help in Accidents and in Sickness, intended as "a guide in the absence or before the arrival of medical assistance," is a little book published by Alexander Moore, of Boston, and one which, from a hasty examination, we regard as *safe* for family use. Its suggestions appear to be sensible, and such as will be approved by competent physicians.

Cancer, its Classification and Remedies, by J. W. Bright, M. D., is to be noted as a valuable contribution to the literature of this disease. It is published by S. W. Butler, of Philadelphia.

Messrs. Hurd and Houghton have issued a new edition of Judge Haliburton's *Sam Slick, the Clockmaker*, with illustrations by Darley; also a translation of DeMaistre's *Journey Round My Room* (*Voyage autour de ma Chambre*), a gem of French literature in an English setting not unworthy of it, and exquisitely printed withal; and a new novel by Therese Yelverton (Countess Avonmore), entitled, *Zanita*, a Tale of the Yosemite. Mrs. White's *Little-Folk Songs* is a marked success in a field where failure is the rule, and success the exception. Verses for children are common as sugar-plums, but there is no poetry so rare as that which is suited to the wants and tastes of a child. These lyrics are quite perfect in their way, and are sure to become classics of the nursery.

The Milk Journal is "a monthly review of the dairy, dairy produce, and poultry yard," published in London, which has already become an authority in its special department. We can furnish it (post free from London) *with the* JOURNAL, at the low price of *three dollars a year* for the two. We can furnish *The Doctor*, "a monthly review of British and foreign medical practice and literature," on the same terms; and *The Journal of Applied Science*, "a monthly record of progress in the industrial arts," edited by P. L. Simmonds (also published in London), *with the* JOURNAL, for *two dollars and a half* a year.

An American subscriber of the London *Chemist and Druggist* writes as follows to the publishers of that journal: —

"In July, 1870, I subscribed for the *Chemist and Druggist*, through a news-agent in our city, and paid the moderate price of *six* dollars currency per annum, and I should have continued my subscriptions at the same rate, rather than not have the paper."

Our readers will remember that we furnish the *Chemist and Druggist* for *two dollars a year*, or *with the* JOURNAL for *two dollars and a half*. These rates, and those of all the foreign periodicals on our clubbing list, are the result of special arrangements with the publishers, and are much lower than have been offered before in this country.

We would take this occasion to remark that our clubbing list remains the same as published in our number for June, 1870. Copies of it will be sent to any address on application.

The publishers of *Scribner's Magazine* will enlarge it with the new volume, and the price will be $4.00 a year. We will send it *with the* JOURNAL on receipt of that price. It is now one of the most popular of the magazines, and promises to become even more of a favorite in its enlarged form.

The American Naturalist issues a double number for October, with full reports of the natural history section of the last meeting of the American Association. This excellent monthly deserves a much wider circulation than it has yet won. Our subscribers should recollect that we furnish it *with the* JOURNAL for $4.00 a year, the regular price of the *Naturalist* alone.

We have received sets of the *Reports* of the State Boards of Agriculture of Michigan and of Connecticut, and also of the United States Department of Agriculture, for all of which we return our thanks. We should be happy to receive similar sets of documents from other States that issue them.

Medicine.

MEDICAL PHILOSOPHY.

It is a matter of regret that in the regular profession of medicine there is no system of medical philosophy. We have a vast accumulation of facts, the result of the most careful and scientific observation and experiment, and a certain amount of deduction as the result of investigation, but no comprehensive philosophy, to govern the physician in his treatment of disease.

It is believed that medical art has kept pace with other improvements, for which this century is so remarkable, and what is to be the progress in the future no one can predict: but no one can doubt that it will make even greater advances than in the past.

The want of a comprehensive medical philosophy to which I have alluded, may not be recognized by a physician already established, but to the young man just commencing practice the want of such a guide must be keenly felt.

The homœopath has a simple philosophy in the words *Similia similibus curantur*, and while it captivates many intelligent people, a large majority of physicians do not believe it to be true, and are incredulous as to the capability of matter to be subdivided to the extent claimed by their practice.

If the medical profession are ever to have a medical philosophy which is true, it must be the legitimate deduction from facts, and with a view to take the first step in the desired direction, you will permit me to announce a single principle by which I have been governed during a somewhat extensive practice.

It is well known by physicians that the human body is composed of quite a number of substances, such as albumen, globuline, fibrine, caseine, and kerotine, among the proteine compounds; gelatine, chondrine, fatty matter, — organic acids and inorganic acids, etc.; till we come to the metallic bases: potash, soda, ammonia, magnesia, iron, and manganese. Now in medical practice I never give, under any circumstances, any mineral either in the form of a salt or compound that does not enter into the human organization, as it would become a foreign substance incapable of assimilation, and therefore poisonous to that extent — or at least a foreign body. On administering an organic substance, or any of the minerals which constitute a part of the human system, there is a provision to discard or eliminate what is not wanted — if in excess of the requirements. But if you give lead or mercury, copper or silver, zinc or tin, there is in nature no arrangement to eliminate it from the system.

Physicians deplore lead or zinc poisoning; why then should they give the salts of either, to produce a temporary action, regardless of subsequent effects? Every conceivable drug has been recommended for every known disease, but if the physician would adopt the simple rule I have indicated, he would have the satisfaction of feeling that he had at least done no harm to his patients that would return at some future time to torment him.

J. H. STEARNS, M. D.,
Surgeon, National Asylum for Disabled Soldiers.
AUGUSTA, MAINE.

NOTES AND COMMENTS.

EXPLOSIVE PRESCRIPTIONS. — Several months since we stated in the JOURNAL that a mixture of chlorate of potassa and tannin was a dangerous combination, and should not be prescribed by physicians or compounded by apothecaries. A case of severe injury resulting from the explosion of this mixture has recently come under our notice. An apothecary in a neighboring city undertook to rub up in a mortar two drams of chlorate of potassa with one of tannic acid, as prescribed by a physician; the mixture exploded violently, burning the hands and face of the manipulator so severely that he was confined to the house for a week. A mixture left with an invalid friend, by a homœopathic physician, to be dissolved and used as a gargle in a throat affection, was found upon examination to be composed of the dangerous materials, and we find it is often prescribed by some practitioners. Its dangerous nature should be generally understood.

CURIOUS FRAUD. — We were shown recently a quantity of what was sold for "German Saffron" by a wholesale druggist, which upon examination proved to be shreds of Campeachy logwood and fustic, ingeniously blended or matted together, and moistened with a little heavy syrup. The deception was so perfect that an experienced druggist purchased the article and sold it for genuine saffron. In the history of fraudulent imitations, we have met with no instance so remarkable as this. Saffron has been for a long while scarce and high, and this circumstance has stimulated some enterprising and ingenious cheat to devise a cheap substitute. The amount upon the market we learn has been quite large, and druggists will do well to examine closely the article as offered for sale.

WILL CHEMISTS EVER MAKE THE VALUABLE ALKALOIDS, QUINIA AND MORPHIA? — There is but little doubt in our mind that they will. The synthetical production of conia has already been accomplished, by Schiff, a German chemist, and this result, so unexpected and remarkable, paves the way for the artificial production of the other alkaloids. The conia of Schiff, is produced by first forming dibutyraldine, and then subjecting it to dry distillation, from which one of the products obtained is conia, having the chemical composition and the poisonous properties of the natural alkaloid. This is one of the greatest triumphs of modern organic chemistry, more remarkable than the production of valerianic acid, which so excited the great chemist Liebig, twenty years ago. The field for research and experiment in organic chemistry is a wide one, and whoever discovers methods by which the alkaloids peculiar to the poppy plant and Peruvian bark can be artificially produced, will acquire a name and fame which will be lasting.

BEHIND THE BARS. — Several months ago we called attention to a series of quite remarkable papers with this title, which were appearing in the *Courier* newspaper of this city. The papers have been collected and published in book form, a copy of which we have received. The book is one which every physician should read, as it treats upon a subject which most intimately concerns the medical profession, those who are daily consulted regarding the care of the insane, and the conduct of our asylums designed for their treatment. The author of the book is one who has the confidence of all acquaintances and friends, and no one can call in question the motives which prompted its preparation. It is a matter of regret that the name of the author is not given, as it would add greatly to its influence upon readers. We have in the former notice spoken of the nature of the work, but at a future time shall endeavor to present some extracts, which will more clearly represent its designs and character.

HARD WATER AND HEALTH. — Some time ago we referred to Dr. Letheby's views on this subject. They led to no small controversy in Edinburgh and elsewhere, and both sides have since been busy in collecting facts to support their opinions. Dr. Charles Wilson, of Edinburgh, has recently published the results of his investigations. He gives a list of sixty-five towns, with their death rates, and the hardness of the water supplied to them. We give a summary abstract of the tables, in which the towns are classified according to the degrees of hardness of water supply:

Deg's of Hardness of Water.	Average Degree of Hardness.	Average Death-rate per 1,000 of Population.
Over 10	16.0	21.9
10 to 6	8.0	24.9
6 to 2	3.8	26.3
2 and under	1.3	28.5

These lists include towns placed under every variety of conditions. There is but one thing comparable among them, and that is the quality of the water supply; and nothing can be clearer than that the death-rate increases just as the hardness of the water decreases.

The finest breeds of cattle have originated in the hard-water tracts of Lincoln, Leicester, York, Durham, and Northumberland. The finest horses, too, come from hard-water districts; while, among the gneiss of Shetland and the Grampians, and the slates of Wales and Cumberland, we have the diminutive Welsh and Highland sheep, the Herdwicks, the kylo, and the pony as the characteristic indigenous races. These facts are certainly significant, — at least, until we hear from the other side.

HYDRATE OF CHLORAL IN INSANITY.

DR. J. B. ANDREWS has some interesting observations on the physiological action and therapeutical use of chloral, in the *American Journal of Insanity* for July. Dr. Andrews has used the article extensively in the New York State Lunatic Asylum, and concludes regarding its physiological action: "1. That the effect of chloral is to reduce the number of pulsations. (In experiments from 84 to 54.) 2. That the primary action is to increase the force of the heart's action and arterial tension. 3. That in large doses, within safe limits, the pulsations are not reduced in number proportionately to the size of the dose, but the effect is more prolonged. 4. That the secondary effect is to diminish the force of the heart's action and the arterial tension."

Chloral has been used to the extent of *nine pounds* in the New York Asylum, having been prescribed in three hundred and seventy cases. The average length of time of administration has been to the men thirty-nine days, to the women forty-three days. In a case of melancholia, marked by the

nost distressing delusions and wakefulness, it was given in twenty-grain doses, for two hundred and ifty-seven nights, as a hypnotic, without losing its effect, and with the happy result of securing refreshing sleep. The patient recovered. In this case, as in others, the value of the remedy was ested by occasionally intermitting the dose. Sixty grains were administered during an attack of mania or one hundred and ninety-five nights in succession.

The value of the remedy in insanity is as a hypnotic, and for this purpose it is of eminent efficacy. Patients who would otherwise be out of bed and oisy at night, to their own injury and the disturbance of a ward, are usually quieted and kept in ed, and at last put to sleep, by a dose of chloral imely administered. The sleep usually lasts from our to eight hours. It is natural, and the patient can be easily aroused. The appetite is not affected y the remedy, no constipation ensues, no ill effects re produced upon the brain, and no appetite for ie medicine is created by its use, as often happens ith opium; but in some instances it produces ausea and vomiting, and unless largely diluted it is pt to cause a burning sensation in the stomach and uces. In some cases its action is so prompt as to ive alarm to attendants. It is advantageously ombined with hyoscyamus and the bromides, to rolong its soporific effects. Dangerous symptoms ave followed a dose of fifty grains of chloral, but as uch as six hundred grains has failed to destroy fe. A case is cited in which a comatose condition as induced by twenty grains. A few fatal accients are ascribed to the remedy, and wisdom sugests caution in its administration.

NTERNAL HÆMORRHOIDS TREATED WITHOUT OPERATION.

DURING the past year Dr. Beekman has treated t the New York Dispensary eleven cases of internal hæmorrhoids, all occurring in females, and all eated without operation. In every case, the only iternal medication consisted in the employment of ie following formula: —

℞ Pulv. Sennæ.
Potass. Bitartrat.
Pulv. Sulphuris, *aa*. . oz. 2.
Pulv. Zinziberis . . oz. ½. M.

This preparation is designated in the Dispensary harmacopœia, as *Pulvis Sennæ Compositus*. The ose, as employed by Dr. Beekman, was a teaspoonl of the powder in molasses, every morning. The cal treatment consisted in the use of the following ntment: —

℞ Ext. Belladonnæ,
Plumbi Acetatis, *aa*. . dr. 2.
Acid Tannic . . . oz. ⅛.
Ung. Adipis, q. s. ut fiat unguentum.

A small mass of the ointment to be introduced ithin the anus thrice daily, after a thorough ablution of the parts with cold water. The duration the treatment was quite various, bearing a direct itio to the severity of the case, ranging from a eek to about five weeks. As far as could be asrtained, recovery took place in every instance, ad no case of relapse has thus far come to Dr. eekman's notice. A few of these patients sufred from hæmorrhage, but not to an excessive nount. Instead of the ointment above mentioned, r. Beekman uses, in private practice, suppositories ade up of the same ingredients, with the exception that cocoa-butter is substituted for the simple ntment — each suppository containing two grains ich of extract of belladonna and acetate of lead, ith four grains of tannin.— *N. Y. Medical Gazette.*

AN ENGLISH HOSPITAL.

FROM the accounts which we find in recent Engsh papers, it is evident that the Royal Orthoedic Hospital, of London, is an exception to the general character of such institutions in that country. An inquest was held a few weeks ago on the body of a little boy who died in this hospital from an attack of diphtheria. Dr. Bourne, the resident house surgeon to the institution, in giving his evidence, expressed his opinion that the attack of diphtheria from which the deceased had died was accelerated, if not produced, by the defective sanitary condition of the hospital. Upon beginning his duties four weeks since, he found the general and sanitary arrangements as bad as they could possibly be, in regard to the diet, the cooking, the cleanliness, and the knowledge and attention of the matron and nurses. There was no order or regularity. The patients were left unwashed for days together, and the atmosphere of the wards was damp and moist, owing to the washing and scrubbing taking place at all hours of the day, instead of early in the morning. The walls of the wards were always reeking with moisture, owing to this cause and all sorts of slops being thrown down the baths in the wards by the nurses. There had been eight deaths from diphtheria since December last. He believed all these deaths to have arisen entirely from the wretched sanitary condition of the hospital, and the defective and neglectful system of nursing. He had frequently got up in the night to attend to the children while crying, the nurse not paying any attention to them. Dr. Bourne's evidence was confirmed in the main by other medical witnesses, and, although it appears some slight improvement has lately taken place in the sanitary condition of the hospital, its present condition was described by one of them as being all "disorder and confusion." The jury took a merciful view of the case, not perhaps as regards the patients, but as regards those responsible for the evils. Their verdict was not "manslaughter;" they found that the deceased died from diphtheria, and recommended the committee to adopt and act upon the suggestions of their medical officers, especially with regard to the appointment of a highly trained nurse.

RELICS OF JOHN HUNTER.

MR. FRANK BUCKLAND has been an indefatigable searcher for relics of the greatest anatomist, physiologist, and surgeon, that England ever produced. Twelve years ago he found John Hunter's bones in the vaults of St. Martin's-in-the-Fields, and got them buried in Westminster Abbey; and he has lately been making a searching examination of the house and grounds that once belonged to him at Earl's Court, Kensington, but are now in the occupation of Dr. Gardiner Hill. According to all local tradition, the house and grounds are very little, if at all, altered since the days that John Hunter lived there. The house was built by himself, and it is such as might have been expected, — without the slightest attempt at effect or useless ornamentation. His favorite room was evidently the large one on the ground-floor, looking out on the park; Mrs. Hunter's rooms being doubtless upstairs. All round the house is a covered cloister dug about six feet into the earth. This cloister probably served the double purpose of keeping the house dry, and of being a good place for keeping live-stock. Mr. Buckland has no doubt that here many of Hunter's smaller animals used for experiments, such as dormice, hedgehogs, bats, vipers, snakes, and snails, for his researches on torpidity, were located; as well as hutches of rabbits, whose unfortunate fate it was to have their ears frozen to prove points connected with blood-circulation. The entrance into these cloisters leads through a very dark, subterraneous passage, at one end of which is a mysterious-looking door, leading into a small room, now used as a receptacle for rubbish. In a corner of this room, there is a largish-sized copper boiler standing out of the wall. "If this old boiler," exclaims Mr. Buckland, "could only tell us what it had boiled!" *One* giant, we know, was boiled in it; for in 1787 John Hunter wrote to Sir Joseph Banks: "I have lately got a tall man. I hope to be able to show him to you next summer." This was, no doubt, O'Brien, the Irish giant, whose skeleton is now in the Hunterian Museum at the College of Surgeons. Close to the boiler are the old (now tumble-down) pig-sties, where, probably, John Hunter kept the little pigs which he fed with madder, so as to cause their bones to become red. The places where his cocks and hens, pigeons — that have become matters of history now — probably lived, and all his other animals, are described. — *The Lancet.*

MEDICAL MEMORANDA.

BROMIDE OF POTASSIUM IN TAPE-WORM. — An interesting case of tape-worm is reported in the *Buffalo Medical Journal* as being cured, after all the ordinary remedies had been employed ineffectually, by taking bromide of potassium, in twenty-grain doses every four hours. After continuing the bromide for three days, and taking half an ounce of the spirits of turpentine, and soon afterwards two ounces of castor-oil, a perfect cure was effected. Two hundred feet were passed from the first medicine, and in a few weeks afterward, after repeating this treatment, fifty feet more were passed, at which time the head was voided. Since that time the patient has rapidly improved in health, and has not been troubled with parasites.

CARBOLIC ACID IN PHTHISIS. — Dr. A. F. Richmond writes to the *Medical Times and Gazette:* "As the cure of tubercles frequently takes place naturally, it occurred to me that nature might be aided by means of this curative agent, administered internally. Accordingly, in the month of March last, in a case of phthisis where the physical and functional derangements were of the most advanced kind, I prescribed two grains in syrup three times per diem — the result being diminished expectoration, and the pulse reduced from 135 to 116, with corresponding abatement of hectic fever. The medicine has been continued without any counteracting or injurious symptoms. From my experience of this case, I would feel justified in using the medicine in cases from the first to the latest stages of the disease; and I think it is proper to bring it under the notice of the profession, in order to elicit observations on it, and to have the merits of carbolic acid, as an internal medicine in cases of consumption, brought to the test."

We have frequently prescribed carbolic acid, alone and in combination with iodine and other remedies, both by the lungs and alimentary canal, with marked benefit, in phthisical cases.

TURPENTINE IN HEADACHE. — Dr. Warburton Begbie (*Edinburgh Medical Journal*) advocates the use of turpentine in the severe headache to which nervous and hysterical women are subject. "There is moreover," he says, "another class of sufferers from headache, and this is composed of both sexes, who may be relieved by turpentine. I refer to the frontal headache, which is most apt to occur after prolonged mental effort, but may likewise be induced by unduly-sustained physical exertion, — what may be styled the headache of a fatigued brain. A cup of very strong tea often relieves this form of headache; but this remedy, with not a few, is perilous, for, bringing relief to pain, it may produce general restlessness and — worst of all — banish sleep. Turpentine, in doses of twenty or thirty minims, given at intervals of an hour or two, will not only remove the headache, but produce in a wonderful manner, that soothing influence to which reference has already been made."

IRON ALUM AS A HÆMOSTATIC. — A strong solution of this salt in glycerine is admirably

adapted for the arrest of continued profuse bleeding where there is no large vessel to be seen and ligated. For hæmorrhage from the gums it may be applied in powder upon a piece of lint; and epistaxis may be checked by stuffing the nostrils with lint soaked in the saturated solution. If the vessels are much above the size of capillaries, it is not a suitable application; but cases of such capillary bleeding are often dangerous. Internal hæmorrhage may be treated with iron alum, especially gastrorrhagia and enterorrhagia, as well as bleeding from the rectum, when it is to be used as an injection. In these last cases it may be advantageously combined with some preparation of opium.

SPONGE PAPER. — This is an article recently patented in France. It is made of evenly and finely divided sponge added to ordinary paper pulp, and worked, as in the common paper-making apparatus, into sheets of different thicknesses. It is said to have all the peculiarities of sponge, absorbing water readily, and remaining moist a long time. It has been used as dressing for wounds with considerable advantage, and is capable of several important technical applications.

BRAIN WASTING. — J. Crichton Browne, M. D., Lecturer on Mental Diseases to the Leeds School of Medicine, says in the *British Medical Journal*: —

"1st. Women recover from this disease more frequently and rapidly than men. 2d. The earlier the age at which brain-wasting occurs, the better is the prospect of recovery. 3. The more decided the paralytic symptoms, the worse is the prospect of recovery. We owe a debt of gratitude to Dr. Radcliffe for pointing out the value of cod-liver oil and the hypophosphites in debilitating nervous diseases. They supply the essential elements of nerve nutrition in an easily assimilable form, and are unmistakably beneficial in cases of brain-wasting. A tablespoonful of cod-liver oil, and 15 grs. of the hypophosphite of soda, given twice or three times daily, at the outset of such a case, often arrest at once the downward tendency, and induce restoration of mental and muscular power. Sometimes, when these remedies seem ineffectual, doses of from 5 to 15 drops of tincture of opium and sulphuric ether, twice a day, expedite their action, besides conferring independent benefits. The opium gives, as it were, a fillip to cerebral nutrition, and thus diffuses a favorable influence through the whole economy."

PLEIS'S FIT POWDERS. — Dr. A. W. Miller has examined this nostrum — extensively advertised in the East for the cure of epilepsy — and communicated his results to the *Journal of Pharmacy*. He concludes that the remedy is composed of bromide of potassium, disguised by the addition of a little powdered gentian. Each powder contains about 15 grains of coarsely powdered bromide of potassium, and 5 grains of gentian.

COLORED CANDIES. — Some months since a great variety of the candies sold in New York were analyzed by Dr. Endemann, Assistant Chemist to the Health Department of that city, and reported in the *American Chemist*. Reds were either carmine or aniline-red (both harmless). Blues were either ultramarine or Prussian blue (also harmless). Yellows were either saffron, chromate of lime, chromate of baryta, chromate of lead, gamboge, or vegetable colors. Of ten samples five were colored with chromate of lead, and one with gamboge, both poisonous. Greens were harmless, so far as examined. *Starch sugar* is a common constituent of some kinds of candy, and starch is often substituted for gum arabic. In two cases *gypsum* was found, 3 and 6 per cent.; no other inorganic adulterations were detected.

RICINAL COLLODION (COLLODIUM CUM OL. RICINI). — This preparation, a mixture of collodion and castor-oil, is strongly recommended in cholera. The *Archives Générales de Médicine*, says that thirty to forty grammes painted over the abdomen will arrest cholera in the algid stage. It stops the vomiting of cholerine and cholera, and provokes a sudoral crisis, in which the poison is eliminated.

VALUABLE FORMULÆ.

PHOSPHORUS PILLS. — Dr. Ratcliffe, in the *Pharmaceutical Journal*, suggests this formula: Take of phosphorus 6 grains, suet 600 grains; melt the suet in a stopped bottle capable of holding twice the quantity indicated; put in the phosphorus, and when liquid agitate the mixture until it becomes solid; roll into 3-grain pills, and cover with gelatine. Each pill will contain one thirty-third of a grain of phosphorus.

SODA MINT. — This is much prescribed in Philadelphia as an antacid and carminative, and is prepared, according to the *Journal of Pharmacy*, as follows: —

℞	Sodæ bicarb.	℥ ss.
	Spt. ammon. aromat.	℥ i.
	Aquæ menthæ pip.	Oj.

M. Dose, from a dessert-spoonful to a tablespoonful for adults; from half to one teaspoonful for infants.

CARBOLIC CERATE. — Mr. Charles A. Bœhme suggests the following as an excellent formula: —

℞	Adipis	℥ x.
	Ceræ albæ	℥ v.
	Terebinth. Can.	℥ i.
	Acid carbol.	ʒ i.

Melt the lard and wax together, add the balsam fir, and when it begins to cool, stir in the carbolic acid. The addition of the balsam fir corrects the disagreeable odor of the acid, and renders the preparation slightly adhesive.

PRESERVATION OF TINCT. KINO FROM GELATINIZING. — To protect this tincture from change, Mr. J. M. Wood uses this formula: —

℞	Kino in fine powder	℥ i ss.
	Alcohol, .835	f. ℥ viii.
	Water	f. ℥ iv.
	Glycerine	f. ℥ iv.

Mix the alcohol, water, and glycerine and having mixed the kino with an equal bulk of clean sand, introduce into a percolator and pour on the menstruum.

AMANDINE. — The London *Pharmaceutical Journal* gives the following recipes: —

1. Bitter almonds (blanched), 4 oz.

Beat them in a mortar with a small quantity of water to a smooth paste, and add: —

Orris root, in fine powder	
Soap, in fine powder, each	1 oz.
Glycerole of starch	2 oz.
Clarified honey	1 oz.
Oil of bitter almonds	5 drops.
Oil of lavender	½ fl. drm.
Oil of bergamot	1 fl. drm.

Tincture of cochineal, q. s. to color. Mix.

2. Blanch 12 oz. of bitter almonds, and beat them in a mortar with a small quantity of rose or other water to a smooth paste; then add 7 oz. of rice flour, 3 oz. of bean flour, 1 oz. of orris powder, and when perfectly mixed, ½ oz. carbonate of potash, dissolved in rose-water; again beat together, and add 3 oz. of spirituous essence of jessamine, 2 drops of oil of rhodium, and one of neroli.

3. Take of fine pale honey (or strong syrup) 4 oz., white soft soap made from lard and potash, 2 oz., mix them thoroughly in a Wedgewood mortar, adding, if necessary, two or three teaspoonfuls of solution of potash, so as to produce a thoroughly homogeneous paste. To this add and rub in by degrees, and very gradually, 3½ lbs. oil of almonds, previously mixed and scented with

Essential oil of almonds,
Essence of bergamot, of each, 3 fl. drms.
Oil of cloves,
Balsam of Peru, of each, 1½ drm.

And continue the trituration until the whole as sumes the appearance of a rich transparent jelly Finally, put the paste into pots or wide-mouthe bottle.

[NOTE. — The balsam ought to be triturated with a little of a mond oil, warm, before adding to it the rest, and, after all th scents are added, the oil should be allowed to settle for two or thr days, and the clean portion only used.]

In using, a lump of amandine, the size of a larg pea, is rubbed with a few drops of warm water, an the rich, white lather applied to the hands, fac neck, etc. In a short time the skin may be wipe with a soft napkin.

ESSENCE OF MOSS ROSE. — This is from th same authority: —

Otto Rose	ʒ iss.
Ess. Ambergris	ʒ iiss.
Ess. Musk	℥ j.
Alcohol	℥ xv.
Aq. Rosæ Conc.	℥ x.

ANISEED CORDIAL. — The following is a goo recipe: —

℞	Ol. Anisi	ʒ ss.
	Sacch. Alb.	℥ ij.
	Syr. Simpl.	℥ iij.
	Sp. Vin. rect.	ʒ viij.
	Aq. destill.	℥ xxx.

The oil to be well rubbed with the sugar; ad the water gradually; mix the remaining ingred ents, and filter.

FUMIGATING PASTILLES. — The *Druggist's Ci cular* gives these two recipes: —

1 — Take Benzoin	2 ounces.
Balsam of Tolu	
Yellow Sandal-wood, of each	4 drachms.
Nitre	2 drachms.
Labdanum	1 drachm.
Charcoal	6 ounces.

Mix with a solution of gum tragacanth, and d vide the mass into pastilles, cone-shaped, and dr them in the air. The foregoing is the formula o the Paris Codex.

2 — Take Benzoin	4 ounces.
Cascarilla	½ ounce.
Nitre and	
Gum Arabic, of each	3 drachms.
Myrrh	1 drachm.
Oil of Nutmeg and	
Cloves, of each	25 drops.
Charcoal	7 ounces.

All in fine powder. Beat them to a smoot mass with cold water q. s., and form into sma cones and dry in the air.

WASH FOR THE GUMS. — The French prepar tion known as *Eau de Botot* is made as follows: —

℞	Anise-seed	80 parts.
	Cloves	
	Cinnamon, āā	20 "
	Oil of peppermint	10 "
	Cochineal	5 "
	Vanilla	1 "
	Rectified spirits	800 "
	Rose-water	200 "

Digest for about a week and filter; then add of
Essence of amber . . . . . . 1 part.

A few drops in a glass of water, to rinse the mout with.

CUNDURANGO. — It can hardly fail to cause th heart of the American pharmacist to bound for joy to know that Dr. Bliss, from blissful Washington has announced the blissful intelligence that a carg of Cundurango has arrived in New York, whicl will be furnished to the profession at the highes possible prices. "See, the conquering hero comes!" The very name Cundurango has a high and mighty conquering sound — sweetly blended of High Span ish, Guinea Nigger, Fiji, and Whang Doodle. Dr B. has taken steps to Helmboldize the drug at once We will soon see it marching on across the Conti nent, side by side with the other heroic names which, by the magic of paint and cheap blacking blazoned on every bridge, fence, and crag, from the Atlantic to the Pacific, have been stencilled upon the great American heart. — *Chicago Pharmacist.*

Boston Journal of Chemistry.

Volume VI. BOSTON, DECEMBER, 1871. Number 6.

Familiar Science.

UNRECOGNIZED POISONS.

So essential to comfort and happiness is good ealth, it would seem that if other considerations iiled to lead us to take good care of our bodies, iere selfishness would control our conduct. 'here are many ills incident to the flesh which annot well be kept at bay, but a large majority f those which torment and destroy the human imily are undeniably preventable, or can be 'arded off or mitigated by intelligent care and ie proper observance of hygienic laws. The auses of disease are manifold, and they exist nseen in the air we breathe, in the water we rink, in the food we consume, and in the clothig we wear. Thousands of human beings have ist their lives from *poisons;* not such as are btained of chemists and apothecaries, but those hich result from causes incident to our mode f life; poisons which cannot be readily seen, andled, or weighed. The progress of the uman family towards civilization and refineient has resulted in a complete change in the onditions under which it exists. The men and vomen of this age, residing in civilized commuities, no more conform to the habits of their ncestors than to those of the animals they rear; id whilst they are surrounded with the manild comforts, luxuries, and conveniences which iodern science and art have devised, new aveies have been opened for the approach of disise, and new sources for the development of odily poisons have been created. If science id not kept pace with the multiplication of iese hurtful influences, and proved adequate to oint them out, the race long since would have ecome extinct. It is not necessary that we low our retrospective glances to take a very r-reaching sweep into the past, to learn that e air breathed by our ancestors was such as iture provides, unmixed, unadulterated. Inoors as well as out of doors, the air that came esh from the hills had almost unimpeded cirlation. No "hot air" furnaces and "red hot" oves loaded the in-door air with poisonous ises and suffocating dust, and raised it to a mperature corresponding to "blood heat." 'hey had plenty of smoke no doubt in their vellings, for their imperfect chimneys, even ider a draught urged by blazing logs of hicky, would not always lead upwards the blue ass of unconsumed fuel. But fresh wood ioke they did not mind, even when it was inse enough to tan the skin. The air which ey breathed was crisp, and full of oxygen, d the respiratory valves were sufficiently vigous to intercept the offending matter and pel it.

The quaint old English writer, Holinshed, hose chronicles we read with so much interest, garded smoke not only as healthful, but as a medicine." He says, in speaking of the innovations of the times, the introduction of chimneys, etc.: —

"Now we have many chimneys, yet our tenderlings do complain of rheums and catarrh and poses. Once we had nought but a reredos (a fire-place), and our heads did never ache, for the smoke of those days was a good hardening for the house and a far better medicine to keep the good man and his family from the quack or pose, with which then very few were acquainted. There are old men yet dwelling in the village where I remain who have noted how the multitude of chimneys do increase, whereas in their young days there were not above two or three if so many in some uplandish towns of the realm, and peradventure in the manor places of some great lords, but each one made his fire against a reredos in the hall where he dined and dressed his meat. But when our houses were built of willow, then we had oaken men; but now our houses are built of oak, our men are not only become willow, but a great many altogether men of *straw*, which is a sore alteration."

The partially carbonized particles of fuel which escape from burning wood in the form of "smoke" are irritating to the mucous surface of the air passages when inhaled, and Holinshed's views are of course absurd, but there is a wide difference between this "smoke" and the products of combustion which escape into rooms from the burning of anthracite coal. These cannot be seen, and the agents most poisonous are unfortunately not readily detected by the sense of smell. The two gaseous products derived from coal which are offensive and deleterious result from the presence of sulphur in the coal. These bodies — sulphydric acid and sulphurous acid — are exceedingly unpleasant and dangerous to inhale, and hardly any one is so indifferent or stupid as not to be alarmed, or at least annoyed, by their presence in dwellings. But the amount of sulphur in coal is small, and in a few moments after fresh fuel is added to a fire, it is changed or volatilized by heat, and the disagreeable odor passes away. Another class of bodies, at least equally poisonous, but without special odor, continue to be evolved from the burning coal so long as any remains unconsumed, and they pass into rooms as freely as the offensive sulphurous gases. Carbonic acid and carbonic oxide are irrespirable bodies, and the latter is an active poison. Now, from a series of carefully conducted experiments made in the rooms of numerous dwellings in city and country, during the past ten years, we are convinced that there are but few houses in which any form of cast-iron furnace is used, where these gases are entirely absent. It is a well established fact in science that cast-iron is freely permeable to these gases, and if furnace plates contain no cracks or joints, they will pass through into the air chamber, and from thence with the air current into the rooms above. But all furnaces constructed of cast-iron must of necessity have more or less joints, and since no luting or cement has ever been devised which will not be decomposed and crumble under the influence of heat, it is through these open joints that most of the gases find access to dwellings. It is deceptive and wrong for any dealer or manufacturer to claim that in arranging furnaces with joints they employ a cement impervious to gases, and which will not speedily be decomposed. No such cement is known. To the presence of the irrespirable and poisonous coal gases in dwellings much of the poor health and positive illnesses in families are manifestly to be attributed. The human constitution is wisely constituted capable of bearing up under great abuses, but it is impossible to resist them when flagrant and long continued. The strong suffer less than the weak, and women and children who are in-doors much during the day, falter oftener than male members of families, who are absent attending to business in the shop or open air. The subject of warmth in dwellings is one of great importance, as it is most intimately connected with health and happiness, but there is a strange indifference regarding it among cultivated and intelligent men even. But little inquiry is made into the conditions under which household warmth is obtained, and family illnesses are often attributed to anything and everything but the right cause.

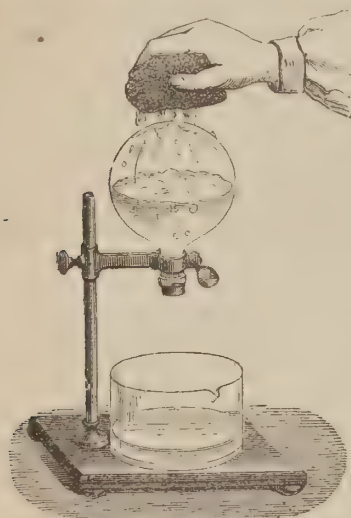
THE BOILING OF WATER.

When a vessel of water is heated to a temperature of 212° F., steam begins to be formed in little explosive bursts at the bottom, and rising in bubbles through the liquid throws it into commotion. If the steam is allowed to escape freely, the temperature of the water rises no higher, all the heat which it receives being absorbed, or rendered *latent*, in the change from a liquid to a gaseous state. This *boiling* is in itself a simple process enough, but it is modified materially by a variety of conditions, giving rise to phenomena some of which do not appear to be understood by people in general, and sometimes not even by those who have charge of steam boilers.

As the steam has to rise from the surface of the water against the pressure of the air, boiling is modified by the degree of that pressure. Diminish the pressure, and the water boils at a lower temperature than 212°; increase it, and the liquid must be heated above that point before it will boil. In fact, the water in our tea-kettles does not boil at exactly the same temperature to-day as it did yesterday, if the barometer has risen or fallen in the mean time. If the mercury has gone up, the boiling water is a little hotter; if it has gone down, the imprisoned steam escapes at a slightly lower temperature, and the liquid is not quite so hot. It would require a delicate thermometer to detect these minute differences of temperature; but if we diminish the atmospheric pressure considerably, the variation becomes readily perceptible. Under the receiver of an air-pump water may be made to boil at a

hundred or more degrees below its ordinary boiling point, or even at the common temperature of a summer day. If we get rid of a part of the pressure by ascending a mountain, the result is similar. On the summit of Mount Washington the boiling point would be a trifle above 200° F., and at the height of 18,000 feet it would be as low as 180°. In some elevated places many substances cannot be thoroughly cooked by boiling.

The paradoxical experiment of making water boil by the application of cold depends upon this lowering of the boiling point by diminution of



pressure. Fill a flask (or any bottle that will bear the changes of temperature without breaking) two thirds full of water, let it boil for some time, then remove it from the source of heat, cork it tightly, and invert it, as shown in the figure. Pour cold water on the flask, and the interrupted boiling will begin again; if we cease the application of the cold water, the boiling stops, and the experiment may be several times repeated. At first the upper part of the flask is full of steam, which exerts quite a pressure on the water. The cold water condenses the steam, and the pressure being thus removed the water boils again, though at a lower temperature than before.

On the other hand, by increasing the pressure artificially we are enabled to raise the boiling point far above 212°. In a vessel containing air condensed into half its ordinary volume water will not boil until it is heated to 234°; under a pressure of four atmospheres, it boils at 294°; under ten atmospheres, at 359°; and under fifty atmospheres, only at 510°.

The boiling point of water may be raised also by increasing the cohesion of its particles. This may be done by dissolving common salt or saltpetre in it, or by removing the air and other gases which it may contain. The elastic force of these gases being increased by the heat, minute bubbles are formed in the interior of the liquid, especially in contact with rough surfaces, and into these the steam dilates and rises. By long boiling the air becomes nearly all expelled, and in such cases the water has been observed to rise even to the temperature of 360° F., in an open glass vessel, which was then shattered by a sudden explosive burst of vapor with a loud report. The force of cohesion had retained the particles of the liquid in contact with each other in a kind of tottering equilibrium, and when this equilibrium was overcome at some one point the repulsive power of the heat stored up within the mass suddenly exerted itself, and the result was an explosion and the instantaneous dispersion of the liquid. If the water had not been kept perfectly still, the unstable equilibrium could not have been maintained so long; and this experiment, like many others that might be mentioned, shows the danger of allowing the water in steam-boilers to remain motionless for any length of time while the fires are kept up. There can be no doubt that explosions have often been caused in this very way.

The boiling point of water is affected even by the material of the vessel in which it is heated. In a perfectly clean glass vessel it may be 2° or 3° higher than in a metallic one. In a copper vessel coated inside with shellac, water will not boil until it attains a temperature of 219°. These phenomena are probably due to differences in the adhesion of the water to the vessel. If the inner surface of a glass vessel is very smooth, distilled water boiled in it will "bump;" that is, it becomes heated a little above the boiling point, and the steam that is formed escapes with a sudden jerk, as if it were a slight explosion; the temperature then falls to 212°, again rising and falling with each burst of vapor. The "bumping" instantly ceases if we put a piece of metal or metallic chips or filings into the vessel. The rough edges of the metal, by breaking up the continuity of the surface, apparently serve to conduct the heat among the particles of the water, and thus to hasten the disruption of their cohesive power.

Intimately connected with this subject of boiling and boiler explosions is that of the *spheroidal state* of liquids, as it is called. Upon this it was our intention to add a few remarks, but the length to which this article has extended compels us to postpone them to another time.

THE DIFFUSION OF GASES.

In another article in this number of the Journal we have referred to the fact that a porous partition is permeable to gases, even though it be of considerable thickness, and of a material as compact as cast-iron. This and similar phenomena depend upon what is known as the *diffusion of gases*, or the tendency of gases to intermix when in contact with each other or when separated only by a porous substance.

If we fill a bottle with a light gas, as hydrogen, and another with a heavy one, as carbonic acid or chlorine, and connect the two by a long tube passing through the corks, we find that the two gases will soon become thoroughly mingled; and this will take place even if the bottle of lighter gas is placed *above* the other. The hydrogen will descend, and the carbonic acid, which is more than twenty times heavier, will ascend, in apparent defiance of the laws of gravity, until the two are equally mixed in both bottles. If the lower bottle be filled with chlorine, which has a distinct yellow color (and which is *thirty-five* times heavier than hydrogen) we can see it as it gradually rises and blends with the colorless gas above. The experiment shows that a gas is virtually a vacuum to another gas. One spreads itself through the other, as through empty space, the only difference being that the expansion is not so rapid in the former case.

The simplest and at the same time the most striking experiment to show the diffusion gases through a porous partition is by means an unglazed porcelain cup, such as is used many forms of the galvanic battery. Close tl mouth of this cup with a cork, through whic passes a glass tube two or three feet long; an let the open end of the tube dip into a vessel water. Now fill a bell-glass with hydrogen ar hold it over the cup so that the cup is immers in the hydrogen (or let a rubber tube from a h drogen apparatus pass into the bell while th held over the cup), and there will be an insta rush of bubbles from the lower end of the tul up through the water. This shows that the h drogen passes at once through the porous cu and mixes with the air inside. If now we r move the bell-glass, the water instantly rises the tube; showing that the hydrogen has pass out the same way as it entered. If the water colored with a drop or two of red ink, its rap rise in the tube can be better seen. In bo cases it can be proved that the air is passi through the porous partition at the same tir with the hydrogen, but in the opposite directi and more slowly. The greater the difference the density of the two gases, the greater the d ference in the rapidity with which they diffu into each other.

That cast-iron is thus permeable to gas though to a less degree than the porcelain c in these experiments, has been established b yond a doubt. When it is red-hot, the gases, might be expected, pass through it more read than when it is cold. Some have denied that is permeable at all in the latter case, but rece experiments made in England go to show t contrary. The ground about cast-iron gas-pipe the joints of which were made hermetically tig so that no direct leakage could take plac has been found to become saturated with g There could be no doubt, under the circumstanc that the gas passed through the iron to mix w the air in the earth outside. In the case gas-pipes laid near wells, the water has be found to be contaminated by the escape of t gas. And what is even more remarkable, it h been found that when gas-pipes and water-pip were laid near each other, the gas escaped fr the former and mixed with the water in the l ter. An instance of this kind recently occurr at Croydon, near London, and the same thi has been observed elsewhere.

The diffusion can of course be prevented coating the pipes on one or both sides with c tar or some of the paints that have been su gested for the purpose. It would seem to true economy to coat water-pipes on both sid and gas-pipes on the outside, to protect th from rust, if for no other reason; but in t country this is rarely, if ever, done.

BOUND FOR THE NORTH POLE.

Arctic exploration appears to have receiv a new impetus of late. To quote the words *The Academy*, "Not only are there more than dozen expeditions, greater and smaller, besiegi the icy fastnesses of the arctic region at alm every point in the circle of its unknown ar but the whole of these, with two exceptions, a independent of any public aid, and have be undertaken at individual risk, in the hope direct mercantile as well as scientific gain."

The Germans are conducting two important ;peditions. One sailed on the 25th of June, ıder the veteran traveller Von Heuglin, and is ·epared for a fifteen months' crüise in the Si- ·rian seas; taking a route through the Strait of ova Zembla and across the Kara Sea, whence ı attempt will be made to double the North ape of Asia, and to reach the island of New iberia. The other, undertaken by Payer and Veyprecht, left Tromsö, in Norway, on the 19th ' July, in a vessel appropriately named the *björn*, or "Ice-bear," and returned to that port ı the 3d of October. The telegraphic report ınouncing her return is brief, but it suffices to ow that the expedition penetrated as far as 79 ·g. of latitude in the region between 42 and 60 ·g. of eastern longitude, and discovered an open a, apparently leading eastward to Polynia and fording a practicable access to the North Pole. r. Petermann therefore concludes that the en- rprising pioneers advanced through the glacial ıne encompassing the Pole by the Gulf Stream, e direction of which, as discovered in 1869 by e steamer *Albert*, pointed exactly towards the ot up to which Payer and Weyprecht have lvanced, — longitude 43 E. and latitude 79 N. t a latitude of 75 or 76 N. the Gulf Stream owed a warmth of 4 deg. Réaumur, a tem- ·rature unapproached at any other spot in those gions, and on that account Dr. Petermann nsiders it the only route by which the Pole n be reached. On this point there has long ·en a dispute between Dr. P. and Captain oldewey, another of the chief German au- orities on arctic geography, and the partisans ' the former are highly gratified at the con- rmation of his views which the results of this ;pedition appear to furnish.

A Swedish expedition, in two government ·ssels, under Professor Nordenskjold, sailed ' May for the exploration of the seas between reenland and Spitzbergen. Several Norwe- ·an vessels, commanded by experienced arctic ·vigators, and equipped by the government ·th scientific instruments, are examining the ·ters between Spitzbergen and Nova Zembla. From Scotland, Mr. Lamont has gone in his ·am yacht to the upper part of the coast of ıst Greenland, visited by the German expe- ·ion of last year; and Mr. Leigh Smith, an ıglishman, has fitted out a vessel for the Spitz- rgen seas.

M. Octave Pavy, a Frenchman, has also pre- red an expedition at his own expense, to carry t the plan proposed by Lambert some years o. He intends to go from San Francisco to pan, where he will charter a ship for Kamt- atka. At Petropaulovsk he will buy two ndred reindeer and fifty dogs for an overland ırney by Anadyrsk to Cape Jakan. There lf of the reindeer will furnish fresh meat for ɜ advance from that point, and the remainder ll be left in charge of the native Chukchees. solid ice is found to extend northward from ɜ Cape to the unvisited Wrangell Land, the g-sledges will be used for going on; if there open water, a "modified monitor raft," con- ·ucted for the purpose, will be fitted up and ınched for the polar voyage.

Captain Hall's expedition from this country, d the plans of its leader, have been fully de- ·ibed in the journals of the day. From Uper- ·vik, as our readers probably know, the *Polaris*, having taken on board a good supply of dogs, will cross Melville Bay and attempt to reach the circumpolar region by way of Jones' Sound.

It may be added that the Russian Government is planning an expedition for next summer, to explore the Siberian sea-coast. The special object will be to find the mouths of the rivers Obi and Yenisei, while an inland expedition is to seek their sources.

BRIEF NOTES ON SCIENTIFIC TOPICS.

Sounds from the Aurora. — It has long been an article of popular belief that the aurora is a roarer; that is, that it produces a sound more or less distinct. Scientific men, however, have generally been inclined to regard this auroral noise as a mere illusion. Loomis, in his excellent "Meteorology," says: "There is no satisfactory evidence that the aurora ever emits any audible sound. . . . The sounds which have been ascribed to the aurora must have been due to other causes, such as the motion of the wind, or the cracking of the snow and ice in consequence of their low temperature." But in a paper read at a recent meeting of the Academy of Science, of Paris, M. Becquerel expressed the opinion that the aurora really does make a noise, and in support of this view quoted the observations of Paul Rollier, aeronaut, who started from Paris in December last, and descended 14 hours after in Norway, on Mount Ide, at an elevation of 4,000 feet: "I saw through a thin fog the moving of the brilliant rays of an aurora borealis, spreading all around its strange light. Soon after an incomprehensible and loud roaring was heard, which, when it ceased completely, was followed by a strong smell of sulphur, almost suffocating."

The Spectroscope and the Nebular Hypothesis. — Prof. Kirkwood says that the spectroscope has demonstrated the present existence of immense nebulous masses such as that from which Laplace supposed the solar system to have been derived. It has shown, moreover, a progressive change in their physical structure, in accordance with the views of the same astronomer. In short, the evidence afforded by spectrum analysis in favor of the nebular hypothesis is cumulative, and of itself sufficient to give this celebrated theory a high degree of probability.

Floating of Solid Iron on Molten Iron. — The following explanation of this paradoxical phenomenon is given in the *Scientific American* as a plausible one, to say the least: "According to the dynamical theory of heat, the molecules or particles of heated metals are in a state of great agitation, and the higher the temperature, the intenser the molecular motion. The difference in the specific gravity of melted and solid cast-iron being slight (as 31 to 32 nearly), this constant and fierce movement of the particles of the former prevents a block of the latter from sinking. An analogous action is found in swift running streams or eddies, upon which bodies of considerably greater gravity than water are supported for a long time, and also in the partial suspension of an egg in boiling water."

The Magnetic Needle and Solar Eclipses. — It is well known that the magnetic condition of the earth is disturbed during a display of the aurora, as is clearly shown by the irregular movements of the magnetic needle. A solar eclipse produces similar disturbances. It was observed on the 22d of last December that the magnetic needle followed its usual course till the commencement of the eclipse that occurred on that day. With the beginning of the eclipse it retraced its steps until it reached its minimum declination at 58 minutes past one, which was the instant of totality. From that moment the ascending motion toward the west began anew, until the needle had regained the exact position it had occupied when the eclipse began.

Another New Planet. — In our last number we referred to the recent discovery of three planetoids, all by American observers. On the 14th of September another was discovered by Dr. Luther, of Bilk, who has been the most successful of "detectives" in this field of astronomical research. Of the 117 of these little planets now known he has discovered *twenty*. Prof. Peters, of Hamilton College, has found *thirteen*, and Prof. Watson, of Ann Arbor, *ten*. It is but fair, however, to state that Dr. Luther has been hunting for planets ever since 1850, when he discovered *Parthenope*, the 11th in the list; while Prof. Peters did not enter the field until 1861, nor Prof. Watson until 1863. Of the last score of these planets, all but three have been discovered by these three astronomers, who appear to be now the chief workers in this department.

Recent Observations of the Planet Venus. — Although this "star of love" is our nearest neighbor among the planetary bodies, we know less about her than about several of the family that are more distant. Her very brilliancy has interfered with the study of her face, blinding the observer "with excess of light," and little has been learned on the subject since the days of the indefatigable Schröter. At the beginning of the present year a committee of the "Observing Astronomical Society," in England, arranged for a series of systematic observations of the planet, and no less than thirty-seven gentlemen promised to aid in the work. They began their operations in March, and valuable results have already been attained. Markings upon the surface of the planet have been seen and delineated by several of the observers, and there is a general similarity in the drawings made at the same date by different persons. When the various sketches and observations have been carefully compared, we may expect that our knowledge of the "geography" of Venus will be materially enlarged.

HOUSEHOLD RECIPES.

To Clean Silver. — Wash in hot soap suds (use the silver soap if convenient); then clean with a paste of whiting and whiskey. Polish with buckskin. If silver was always washed in hot suds, rinsed well, and wiped dry, it would seldom need anything else.

To Clean Brass. — The *Technologist* says: "Rub the surface of the metal with rotten-stone and sweet oil, then rub off with a piece of cotton flannel, and polish with soft leather. A solution of oxalic acid rubbed over tarnished brass soon removes the tarnish, rendering the metal bright. The acid must be washed off with water, and the brass rubbed with whiting and soft leather. A mixture of muriatic acid and alum dissolved in water, imparts a golden color to brass articles that are steeped in it for a few seconds."

To Preserve Clothes Pins. — They should be boiled a few moments and quickly dried, once or twice a month, when they become more flexible and durable. Clothes lines will last longer and keep in better order for wash-day service, if occasionally treated in the same way.

To Restore Furniture. — The best preparation for cleaning picture frames and restoring furniture, marred or scratched, is a mixture of three parts of linseed oil and one part spirits of turpentine. It not only covers the disfigured surface, but restores wood to its original color, and leaves a lustre upon the surface. Put on with a woolen cloth, and when dry, rub with woolen.

To Whiten Straw Hats. — Scrape stick sulphur with a knife, mix the powder to a mush with water, plaster it thickly over the straw, and place in hot water several hours; brush off when dry. This is an easy and effectual plan.

The Arts.

[For the Boston Journal of Chemistry.]

MICROPHOTOGRAPHY.

BY CHARLES STODDER.

NEXT to using the microscope, the most important thing to the microscopist is to communicate to others the discoveries he has made. The true student, the discoverer of a new fact in nature, does not wish to keep it to himself, and he cannot bring the world into his study, to see what he has seen with his instrument. Language is, from the different shades of meaning which may be attached to words, utterly inadequate for conveying to others the exact idea that the user wishes to convey. The only resource of the original observer with the microscope is in pictures, which may be multiplied in indefinite numbers. But how to make the pictures? The microscopist may be an artist of sufficient skill to make a drawing satisfactorily; but oftener he is not. The late Professor J. W. Bailey, of West Point, made most superior drawings. The drawings in Professor Agassiz's "Contributions" are masterpieces of this kind of work.

If the observer cannot draw to his own satisfaction, he must employ some other hand and eye. In such case it is rare that the draughtsman understands the subject, and unless the microscopist stands over him, and watches every stroke of the pencil, something will be wrong or omitted. Then when the drawing has been done it must be copied by the engraver or lithographer; and the same trouble again arises, that the artist does not understand the subject, and if not constantly watched, the picture will be most likely wrong. The observer who can both make his own drawings, and do his own engraving, is most fortunate. Such is the case with Professor Lionel S. Beale, of London. Some of his pictures, in his "How to Work with the Microscope," and the "Microscope Applied to Clinical Medicine," were both drawn and engraved on wood by himself. They are among the best pictorial representations of microscopic work. But so rare are such accomplishments that the writer knows of no other case.

The discovery of the art of sun-printing led to the desire of applying it to the microscope, many years ago, and many trials and attempts were made in that direction both in this country and in Europe. There are now in the museum of the Boston Society of Natural History, several examples of daguerreotype pictures taken about twenty years ago, which gave promise of good, useful results. Parties in England, and probably also on the Continent, made attempts in this direction, but it is not known that any specimens of the earlier efforts in Europe have been brought here. In England, Dr. R. L. Maddox has been highly successful within the last ten years. A page of very beautiful specimens of his work is inserted in the last edition of Beale's "How to Work," etc., and *accompanied with a lens* to show the details. The writer has one specimen from Dr. Maddox that is an exquisite and faithful picture of the object, such as no drawing could produce, requiring a considerable magnifying power to show the finer lines. In this country, Dr. John Dean, of this city, wrote a work on the Medulla Oblongata, published by the Smithsonian Institution about 1866. This was illustrated by original microphotographs which were successfully reproduced by L. H. Bradford, by the photolithographic process of cutting, an art that seems to have fallen into an undeserved obscurity, though it is well replaced by the "carbon" process. Dr. Charles F. Crehore, now of Newton, in 1865–66 made many excellent microphotographs of anatomical preparations and natural objects; well showing what the art was capable of doing, but unfortunately for science he found more profitable employment, and did not long practice the art.

It is at the United States Army Medical Museum at Washington that this application of photography has been most usefully applied and carried to the greatest perfection, by the skilful manipulation of Brevet Maj. E. Curtis, M. D., and Lieut. Col. J. J. Woodward, M. D. A vast collection of examples of diseases, wounds, and injuries have been gathered there, and from time to time reports are published for the information of the medical profession, illustrated when needful by photographs of the microscopic preparations that give any information respecting the diseased structures or tissues.

Now the great advantage, the superiority of this mode of obtaining pictures must be unquestioned by the microscopist. If the instrument used is a good one — and that is the *sine qua non*, in microscopy — if the operation is skilful, the picture will show just what the object is without the mistakes of the artist, or of the imagination. There can be no attempt at adding what ought to be seen, or at making the picture agree with a theory. Whatever errors arise will be errors of interpretation; and in this respect all microscopic observations, especially with very high powers, are more or less uncertain.

Dr. Woodward has probably carried the art to greater perfection than any other person, — at least, no examples that we have seen from Europe surpass, if they equal, those of his production. Dr. Woodward is provided with instruments of the very highest grade that can be procured, and consequently his products represent the results to be obtained by such instruments, not by the ordinary microscopes in common use.

Incidentally to the proper work of the Museum, to test perhaps his objectives, to show the results obtained by his instruments on objects that are familiar to all microscopists, he has made many photographs of such objects. A good many of these are now in possession of the writer, taken at various times during the last three years, up to the last summer. Among these, may be specified as the most remarkable, the set of Nobert's test lines, ruled on glass, from 11,000 to 112,000 to the English inch, the finest of which had never been seen by any microscope until within four years; indeed we have no certain information that they have yet been seen in Europe; also Podura scale magnified 756 diameters with Wales $\frac{1}{8}$; the same, and same power, with Powell and Lealand's $\frac{1}{25}$; the same, 2,100 diam., Powell and Lealand's $\frac{1}{50}$; the same done this year with Powell and Lealand's $\frac{1}{16}$ immersion, 1,200 diam., two pictures, showing the totally different appearance presented by the same object by merely a change of illumination, and the caution that must be exercised in interpreting microscopic appearances. There is a set of eight anatomical preparations, the photographs taken early the present year by Dr. Woodward, and published July 13th, to show the improvements and progress recently made; all of them are beautifully clear, distinct, and sharp.

One of the most difficult tests of the microscope known is the resolution of striæ of the diatom *Amphipleura pellucida*. Messrs. Harrison and Solitt, of Hull, England, claimed to have resolved the striæ of this plant about twenty years ago, and stated their fineness to be 130,000 to the inch. As no lines finer than 85,000 had been actually counted at that time, and were not for fifteen years later, all other microscopists agreed that there must have been some mistake. Messrs. Sulivant and Wormley, in this country, failed to see any striæ on the diatom with the best known English and American instruments.

Some writers have said that they had seen the striæ and they were only 40,000 to the inch; others stated that they had seen them, but gave no intelligible account of precisely what they saw. The writer failed to see anything satisfactory with a superior $\frac{1}{10}$ immersion objective, though he did see an appearance of lines. Dr. Woodward, by using blue sunlight, has settled all questions. He has fou that lines or striæ on different specimens vary fr 90,000 to 96,000 to the inch, and has photograph them with several objectives. Among these are o with Powell and Lealand's so called $\frac{1}{16}$ (nearl $\frac{1}{19}$) 960 diam., taken early the present year; anot with the same, 1,000 diam., taken in July; one by Powell and Lealand's (called) $\frac{1}{8}$; one with a Tolle $\frac{1}{15}$ (angle 135° only); two with two of Tolles's (one of them the same instrument the writer used and one with a Tolles's $\frac{1}{6}$. All these were "imm sion" objectives. All the pictures were taken as ne the same power, 1,000 diameters, as practicable, of them show the transverse striation well, but w varying degrees of distinctness. Then there are t positives on glass, taken with the same $\frac{1}{6}$, one of 9 diam., and the other only 256 diam. The striæ a invisible to the naked eye, but by using a l magnifier they can be seen sharp and clear. By known process other than photography, can su *evidence* of what the modern microscope can do produced. We have here permanently fixed, to seen by all, the very thing, so to speak, that t microscopist saw in his instrument, for what is se in the microscope is not the object on the stage b a picture formed and seen close to the eye. He are no mistakes of draughtsman or engraver, false lines or blots, no imagination, no theory to helped along, but a copy, perfect in every deta except color.

Dr. Woodward has from time to time published f accounts of his apparatus and process, so that a one can adopt and use the same. In his last pap of July 13th, he explains the simplest, most efficie and cheapest, and he states that any one can no make such microphotographs cheaper than they c obtain drawings and engravings.

MEMORANDA IN THE ARTS.

A NEW DIVING MACHINE. — The Naples corr spondent of a Prussian journal describes a new div ing machine for laying torpedoes, etc., under ship invented by a Venetian, named Toselli. It is calle *talpa marina* (the sea-mole), is made entirely of ir and bronze, and is in the shape of a cylinder, fo metres long and about eleven decimetres in diam ter. The machine is in four compartments, o above another. In the first is compressed air f the use of the diver; in the second, the diver hir self; in the third, an apparatus for lowering raising the machine in the water; and in the fourt a quantity of lead to keep the machine in a vertic position. A number of drills and other tools a also fitted into the surface of the machine, to enab the diver to perform various destructive operatio under water. Not long ago Signor Toselli d scended in his machine in the Bay of Naples, i the presence of several high naval officers. H sank to the bottom of the bay, a depth of sevent metres, and remained there for an hour. Durin this time he amused himself by writing a letter d scribing his sensations to Professor Palmieri, th director of the observatory on Mount Vesuvius. I this letter, which is dated "From the bottom of th Bay of Naples," Signor Toselli says that the elemen surrounding his machine does not look like wate but like a mass of transparent glass, compact, im movable, and transmitting sufficient light to enabl him to write and read. Countless fish were passin by in all directions. The stillness was almost pain ful; in other respects Signor Toselli felt quite wel and had a peculiar pleasure in the act of breathing The *talpa marina* will hold two persons comfortabl and a sufficient quantity of compressed air can b carried in it to enable them to remain under wate for fifty hours at a stretch.

SAFE STORAGE OF GUN-COTTON. — The Stow market catastrophe in England has drawn genera

attention to this matter. Fears have been expressed that the manufacture of gun-cotton might be dangerous, but it appears that when made by the Abel process so-called, there are no grounds for apprehension. By this process gun-cotton is kept in a wet condition, and remains, therefore, absolutely inexplosive and uninflammable throughout all the stages of manufacture. It is not until the gun-cotton comes to be dried and stored that any danger or possibility of explosion arises. On this point the teaching of the Stowmarket explosion is quite clear. No gun-cotton except that which was dry, or on the drying stoves, ignited; and the works now contain a quantity of the *damp* gun-cotton, which was in process of manufacture when the explosion occurred. This fact has led to the suggestion that the substance might be stored in the wet state, and dried only when required for use. In this respect gun-cotton has a decided advantage over gunpowder, and it is one which ought to be practically applied.

A New Partition Wall. — A new kind of wall is coming into use in England, the advantages claimed for which are the very important ones of non-absorbency of moisture, non-conduction of heat, economy of space, a washable surface, and, withal, cheapness. Over a framework of strong cross-wires, of about one eighth of an inch in thickness, there is woven a compact layer of fibrous matter, which is saturated with a solution that renders it fire-proof. It is then subjected to a very powerful pressure. A coating of light Scott's cement is then put upon it for inside facing, and of Portland cement for outside facing. By this means surfaces are made impermeable to moisture, smooth, and easily washed with water, thus saving the expense of repeated lime washings. It is formed into slabs in iron frames, which are put together and closely and securely fastened with bolts. The slabs are from one and a half inch to four inches thick. They serve as superior panelling for dividing walls and partitions. Where space is of importance, it has the advantage, perhaps, over concrete walling, in enabling a wall to be made of not more than one and a half inch or two inches in thickness, and yet its quality is said to greatly deaden sound.

Photographic Printing in Colors. — We learn from the *Philadelphia Photographer* that this is effected by mixing the colors with a solution of bichromate of potash, spreading the color thus mixed over the surface to be printed, and exposing it to light under the negative. The spots where the color is not fixed by the decomposition of the bichromate, may be washed off; of course as many negatives must be used as colors are intended to be used, and the parts which are not to receive any of a given color are to be carefully covered in the negative for that color. This process may be used on textile fabrics, glass, etc. The articles to receive the picture should be covered with a varnish of gum damar in benzine, to which a little alcohol has been added, to prevent cracking.

Economy in Steam Power. — A Boston correspondent of the *American Artisan* states that he is running a twenty-horse engine constantly with the heat obtained from the exhaust steam of another twenty-horse engine, thereby doubling the amount of power previously produced by the consumption of a pound of coal. The apparatus used consists of a tubular boiler, twenty-six inches in diameter and ten feet long, with sixty $1\frac{3}{4}$ inch iron tubes in it. This boiler is placed in an upright position and filled half full with bisulphide of carbon, and is heated by passing the exhaust steam through the tubes, from top to bottom. The steam is completely condensed in passing through; and the temperature of the water of condensation discharged at the bottom of the boiler does not exceed 120° Fahr. at any time. The latent heat of the steam is absorbed by the bisulphide of carbon, which is converted into vapor very rapidly under a pressure of fifty pounds to the inch. This vapor is used to drive the second engine, which does as much work as the first is doing. The bisulphide vapor after being used is condensed by passing through a coil of iron pipe immersed in water, and is pumped back into the bottom of the boiler as fast as condensed, and used continuously, the waste not exceeding half a gallon per day. Only forty gallons are required to work the engine successfully.

New Mode of Obtaining the Extract of Hops. — A Mr. Newton, in England, has patented a new method of extracting the useful substance of hops. The process is based upon his discovery that the light products of petroleum, naphtha, etc., are rapid and complete solvents of the essential oils and of the bitter principle of hops, while at the same time they have no solvent action on the other constituents of the plant, which are either useless or hurtful. The hops are simply steeped in the naphtha, under a moderate heat. The apparatus employed is similar to that used for bisulphide of carbon when employed for similar purposes. The lighter hydro-carbons, which boil at 100° Fahr., are preferable for this purpose.

A Hard Cement. — A foreign journal says that a French mason, in repairing the stone steps leading into a garden, used Portland cement mixed with finely divided filings and borings of cast and wrought iron, instead of sand; and that the mass has become so hard that it cannot be broken either with hammer or pickaxe.

PRACTICAL RECIPES.

Shoe Blacking without Acid. — From 3 to 4 lbs. of lamp-black and $\frac{1}{2}$ lb. of bone-black are well mixed with 5 lbs. of glycerine and treacle. Meanwhile, $2\frac{1}{2}$ oz. of gutta percha are cautiously fused in a copper or iron saucepan, and 10 oz. of olive oil added, with continual stirring, and afterwards 1 oz. of stearine. The warm mass is added to the former mixture, and then a solution of 5 oz. of gum senegal in $1\frac{1}{2}$ lbs. of water, and one drachm each of oil of rosemary and lavender may be added. For use, the blacking is diluted with three to four parts of water. This blacking keeps the leather soft, and tends to preserve it.

Bottle Wax. — The ingredients are shellac, two pounds; rosin, four pounds; Venice turpentine, two and a half pounds; red lead, one and a half pounds. Melt the shellac and rosin cautiously in a bright copper pan, over a clear charcoal fire. When melted add the turpentine, and lastly, mix in the red lead. Pour into moulds, or form sticks on a warm marble plate. The gloss may be produced by polishing the sticks with a rag until they are cold.

Fine Blue Ink. — Dissolve ten parts of yellow prussiate of potassa in 160 parts of pure distilled water; gradually and while stirring add to that solution a mixture of five parts of a solution of perchloride of iron (sp. gr. 1.480) and 160 parts of water. The ensuing precipitate is collected on a filter, and washed with distilled water until the water begins to assume a blue color, after which the precipitate, which will then have become completely soluble in distilled water, is to be dissolved in 400 parts of that liquid.

To Prevent Polished Materials from Rusting. — The following has been tested and approved by good authorities: Put half an ounce of solid paraffine into a wide-mouthed glass bottle, and let it melt in boiling water; then add one and a half ounces of petroleum; shake the mixture, after having corked the bottle, until it becomes a cold ointment. In using, cover the metal with it, and wipe off afterwards the greater portion, so that the polish will be little affected. A thin coat is sufficient to prevent polished metals from tarnishing.

Agriculture.

FARM PENCILLINGS AT LAKESIDE.

MILCH COWS.

The extreme sensitiveness of the mammary functions in cows to the influences of cold, fatigue, excitement, unpleasant odors, etc., is indeed surprising. We have been greatly interested in observing the effects of cold upon the milk secretion as seen in the herd of cows upon the farm.

During the past summer, in the hot days in July and August, the animals resorted to the Lake to drink, and after slaking their thirst, they would wade into the water and remain sometimes an hour or two with the legs half immersed. This habit it was found invariably diminished the flow of milk at night, and in order to learn the extent of the diminution careful observations were made. It was ascertained that standing in the water an hour diminished the flow to the amount of 8 or 10 quarts in a herd of thirteen cows. The loss was so great that whenever they resorted to the water they were driven away to the pasture again at once. We have learned that from simply turning the herd into the yard upon a cold day in winter, and allowing them to remain fifteen minutes, the flow of milk was diminished to a serious extent, and consequently the animals are not now allowed to leave the warm stable during the entire winter, except for a brief period upon warm, sunshiny days. Water is brought directly from a well into the barn, and the drinking vessels are arranged so that the animals have to move but a step or two to supply their wants. The nature of the water supply, and conveniences of access, are most important points in the management of milch cows. A draught of ice-cold water, taken by a cow in winter, cuts short the milk yield for the day from one to two pints. Well water drawn into vessels, and allowed to stand a few hours covered, in the warm barn, has its temperature raised several degrees, and this practice should be adopted by all thrifty farmers. It would undoubtedly pay well to slightly warm the water, but this is attended with considerable inconvenience where large herds are kept, unless steam apparatus is used. The influence of a cold current of air, and cold drinking water, upon cows in milk, is not of a transient nature; it extends for a longer period than a day or a week. Many fine animals are ruined by careless exposures every year, and self-interest and feelings of humanity should prompt all cow owners to keep diligent watch over their welfare and comfort.

Cows in milk are often greatly injured by rapid driving from pastures by heedless boys and unthinking men. They should never be urged faster than a walk. Gentleness and kindness of conduct towards cows have a wonderful influence upon the milk pail, and also upon the progeny of the animals. A bad tempered, irascible man ought never to be allowed in a cow stable. A man who will kick a cow in a passion, ought himself to be kicked into the barnyard, and forever prohibited from again coming in contact with the noble animal. The right person placed in charge of a herd of twenty cows, which have been badly managed, will in one month raise the lacteal products so that the increased cash returns will pay his wages. This

is a statement which has been verified more than once.

FEED FOR COWS IN SUMMER.

The past three excessively dry seasons have given much anxiety to farmers regarding the state of their pastures, and attention has been turned to the raising of green crops to keep up the flow of milk. Clover and corn have been the favorite crops, and much discussion has been had regarding them. The experiments made at the farm with fodder corn show that alone it is insufficient to keep cows in perfect condition. There is a stage in its growth embraced within a period of about four weeks when it is capable of *sustaining* a satisfactory flow of milk, but it does not *increase* it when cows are changed from fair pasturage and confined to the fodder. The grasses of the hills and the meadows are manifestly the most proper and natural food for milch cows, and the maize plant is not a perfect substitute. Cows taken from pastures that even are pinched by drought, will fall off in the milk supply, if they are fed solely upon corn fodder cut before the ear begins to form, or at any stage of its growth if it is sown broadcast. It is a great point, however, to have within reach green fodder that will in a fair measure *sustain* the milk secretion when the grasses fail, and corn is so cheaply and easily cultivated that it is upon the whole the most available of any of the green crops. Cows should not however be confined to it alone, but fresh hay or sweet millet or clover should be alternated with the feed. The sweet corn is the variety to be cultivated, and the soil upon which it is grown should not be a stiff, moist loam, but rather a light, warm silicious soil, as this is favorable to the formation of saccharine juices and the richer nutrient principles.

BUTTER.

Our esteemed contemporary, the *Boston Cultivator*, is quite positive that the statement made in the JOURNAL that 16 qts. of good milk is required to make a pound of butter, is incorrect. It is difficult making statements of much value regarding the butter yield of milk, since individual cows, and herds of cows, vary greatly in the quality of the secretion. In addition to our own observations, we have the experiments of Prof. Chandler of New York upon pure milk supplied to the hospitals of that city, which confirm the statements we made. He carefully examined a large number of specimens of country milk, and found that it would take from 12.1 to 15.4 wine quarts to make a pound of butter. Of this milk, we have no doubt, in butter-making upon any farm, it would take 16 qts., as all the butter is seldom obtained from the milk. Wine measure is the legal measure, and as a legal quart of milk does not weigh $2\frac{1}{2}$ lbs. or 2 lbs. 6 oz., it is evident the editor of the *Cultivator* estimates by an empirical standard, which accounts in part for the difference in statements. Very great stories are told by farmers and others regarding the quantity and quality of milk from certain cows, but we have learned to allow a wide margin for those statements; they do not usually bear a close investigation.

APPLE-TREES.

It was without reluctance or hesitation that we decided this autumn to dig up by the roots an orchard of thirty fine, thrifty, fourteen-year-old apple-trees. They were Baldwins, a variety of fruit abounding in all sections of the country. The only crop at the farm, the raising of which has been attended with loss, is the apple crop. Last year it was abundant, and from a careful record of cost in picking, assorting and conveying to market, cost of packages, etc., it was found that the cash returns did not meet expenses. Whenever a "bearing year" comes round apples are in excess of the demand, and must be sold at low prices; consequently the bearing years have come to be regarded with a kind of dread by apple raisers. These fruitful seasons, it is true, have not been very numerous during the past ten years, but those that have occurred have demonstrated the fact that apples do not pay for raising. Immense numbers of trees have been planted within the past twenty years, and among varieties the Baldwins largely preponderate. It is certain that good land is worth more for producing grass, or the cereal grains, than for apples; and hence, instead of planting more trees, some of our best and most sagacious cultivators are removing those already in bearing. Dr. Fisher, of Fitchburg, who had fine apple orchards, has now none, having removed the trees three years ago, and devoted the land to grapes and small fruits. The canker-worm is a pest so annoying and destructive to apple-trees, that if no other discouragement to cultivating apples existed, this would be quite sufficient. The labor of protecting trees is very great, and after all our care we are frequently disappointed in results. For a period of twelve or fifteen years this pest has prevailed in many sections of New England, and the ravages of the worm are dreadful to behold. What can be more disheartening than to see a fine orchard torn and consumed by the loathsome creatures? If the worm, however, spares one half the apple orchards in Massachusetts, and the crops are a fair average the next twenty years, enough fruit will be raised to meet all our wants.

PHOSPHORUS IN PLANTS.

THE wonderful substance (formerly so rare and costly), phosphorus, is so essential an ingredient in the food of plants, that not one of any kind can flourish without it. This highly combustible body, so offensive to taste and smell, and withal so poisonous, enters the plant in combination with oxygen, with which it forms phosphoric acid. The entire supply of phosphorus employed in the arts comes from plants, and they hunt it from the soil atom by atom, and incorporate it into their structures. Animals feeding upon plants abstract the element, and it takes its place in the bones in combination with lime, forming basic phosphate of lime. We gather the bones of the dead animals, and after calcination, subject them to chemical treatment, and thus isolate the phosphorus in a pure state in large quantities. How curious is this cycle of changes and transformations! We can in no way obtain a clearer conception of them than by reflecting upon the fact that the phosphorus found upon the end of every friction match we use in our dwellings has been gathered from the soil by vegetables, and passing through their organization, it has taken its place in the bones of oxen, cows, or horses, and from thence passed into the laboratory of the chemist, where it is fitted to subserve the most useful purposes. If this substance had a tongue, what an interesting history of adventures it could unfold!

The amount of phosphorus or phosphoric acid in the soil is usually insufficient to meet the wants of the plant, and hence the farmer must furnish supplies if he wishes to increase his crops. Formerly there were but two sources of supply, that from manure or animal excrement, and that from the bones of animals; but now we have a third source in the mineral coprolites, or phosphatic deposits, found upon the coast of South Carolina. From these substances what are popularly known as superphosphates are made and sold largely in the market.

The superphosphate of lime, true and simple as known to science, is a rather heavy whitish gray powder, without odor, having an acid taste. It is made from bones, by first calcining them and then dissolving the powder in oil of vitriol. In this method of manipulation we remove from bone phosphate of lime, two equivalents of lime, and replace them with water, and thus we have a superphosphate of lime. By a similar manipulation we can prepare superphosphate from the mineral rock masses before spoken of. The phosphatic deposits from Charleston, contain from 30 to 60 per cent. of phosphate of lime, and when powdered and properly treated with acid, they serve nearly as good purpose as bones, as a source of phosphoric acid. But if the powder is not acted upon by acid, it is almost wholly inert as a fertilizing agent. In this we see the importance of the faithful and skilful treatment of the substances by phosphate makers. Finely powdered bones serve a good purpose in the soil when used in the raw condition, as their structure is different from the coprolites. The gelatine they contain promotes decomposition, and aids in rendering the bony structure assimilable.

TO PREVENT MICE FROM GIRDLING TREES.

MR. E. C. HASERICK gives the following as his method of preventing mice from injuring trees in winter:—

A few years ago I saw it mentioned (I believe in the JOURNAL OF CHEMISTRY) that the way to prevent mice destroying young fruit trees in winter is to trample the first snow fallen around the trees. I found it worked well, but inconveniently, for you have to renew the process every winter, until the trees become large and the bark too hard for the mice to injure them. The philosophy of this method is, that the snow which rests on top of the grass and stubble, and arches thereon so that the mice have access to the trees, is trampled down close to the ground, so that the passage for the intruder is stopped.

To accomplish this result, and more conveniently and profitably, I take about one bushel of shore sand, or other clear sand, to a tree, and spread it about six inches high around each tree. With horse and cart, I fix a hundred trees in three hours. This method has several advantages over the snow-trampling process. First, the snow hugs close to the sand, and needs no trampling, as there is no grass around the tree, and the mice find no passage; and this is done in fair weather, without going out stormy days. Second, the sand is no fertilizer, and will do for several years, as no grass will grow upon it. Third, it will give the tree more vigor. While the grass before robbed the roots of their nourishment and moisture, the dews being evaporated by

the winds blowing through the standing grass, they are now, instead, absorbed by the sand, and easily carried by gravity to the hidden roots. Fourth, it will save all trees formerly destroyed by mice, which is in some years from 25 to 30 per cent. And we learn from the statement of a New York fruit tree dealer, that, according to his own business, he judges that New Hampshire imports no less than $100,000 worth of young trees yearly. This amount can easily be saved by this simple process; and as the season to do it is at hand, I cheerfully give it here for the benefit of my neighbors.

THE IMPORTANCE OF THE FARMER'S WORK.

THE following extract from Edward Everett's address before the New York State Agricultural Society, in 1857, is well worth reproducing:—

"Strike out of existence, at once, ten days' supply of eight or ten articles, such as Indian corn, wheat, rye, potatoes, rice, millet, the date, the banana, and the bread-fruit, with half-a-dozen others which serve as the forage of the domestic animals, and the human race would be extinct. The houses we inhabit, the monuments we erect, the trees we plant, stand in some cases for ages; but our own frames — the stout limbs, the skilful hands that build the houses, and set up the monuments, and plant the trees — have to be built up, re-created, every day; and this must be done from the fruits of the earth, gathered by agriculture. Everything else is luxury, convenience, comfort — food is indispensable. Then consider the bewildering extent of this daily demand and supply, which you will allow me to place before you in a somewhat coarse mechanical illustration. The human race is usually estimated at about one thousand millions of individuals. If the sustenance of a portion of these multitudinous millions is derived from other sources than agriculture, this circumstance is balanced by the fact that there is a great deal of agricultural produce raised in excess of the total demand for food. Let, then, the thoughtful husbandman who desires to form a just idea of the importance of his pursuit, reflect, when he gathers his little flock about him to partake the morning's meal, that one thousand millions of fellow-men have awakened from sleep that morning, craving their daily bread, with the same appetite which reigns at his family board; and that if, by a superior power, they could be gathered together at the same hour, for the same meal, they would fill both sides of five tables reaching all round the globe where it is broadest, seated side by side, and allowing 18 inches to each individual, and that these tables are to be renewed twice or thrice every day. Then let him consider that, in addition to the food of the human race, that of all the humble partakers of man's toil — the lower animals — is to be provided in like manner. These all wait upon agriculture, as the agent of that Providence which giveth them their meat in due season; and they probably consume in the aggregate an equal amount of produce; and, finally, let him add, in imagination, to this untold amount of daily food for man and beast, the various articles which are furnished, directly or indirectly, from the soil, for building material, furniture, clothing, and fuel. The grand total will illustrate the primary importance of agriculture, considered as the steward — the commissary — charged with supplying this almost inconceivable daily demand of the human race and the subject animals for their daily bread; a want so imperative and uncompromising, that death, in its most agonizing form, is the penalty of a failure in the supply."

THE first farmer was the first man, and all historic nobility rests on possession and use of land.

CHEMICAL ANALYSIS.

MERRIMACK RIVER WATER.

THE Merrimack River, which has its rise in the northern part of New Hampshire, and which flows through the eastern section of Massachusetts on its way to the ocean, is remarkable in several aspects, but more particularly for the immense amount of mechanical work performed by its waters in their descent to the coast. These waters are compelled to labor from the moment they start from the cool springs among the mountains of New Hampshire until they are joined to the salt water of the sea at Newburyport. The river and its tributaries probably turn more wheels than any other in the world, and the amount and variety of industrial products manufactured upon its banks are greater than are produced in any section of country of equal extent. The saw-mills, grist-mills, paper-mills, etc., on the small tributaries, are counted by hundreds, while on the river itself are the great manufacturing towns of Manchester, Hookset, Lowell, and Lawrence.

The waters flowing through or past such sources of contamination would naturally be supposed to become loaded with filth, and to be rendered wholly unsuited to any domestic uses. We have recently been employed to make chemical analysis of the river water at Haverhill, a city about eight miles below Lawrence, and consequently below all the large manufacturing establishments upon the stream, and the results are quite unexpected. Instead of finding a large amount of organic matter, it is actually less than is found in many streams flowing through the same region of country, upon which there are no manufacturing establishments. The results of two careful determinations gave precisely equal amounts of organic and inorganic constituents in the water. In the imperial gallon there was contained of

Organic matter	1.75 grains.
Inorganic "	1.75 "

The specimen of water was perfectly clear, and without special odor or taste. What becomes of the vast quantities of dye liquors, wool washings, soap and starch solutions, animal excrement, etc., which are poured into the river above? This is a question somewhat perplexing. At the present time, owing to the drought, the water in the river is low, but still the volume is not small. It is probable that the impurities thrown into the stream are precipitated upon the bottom, or lodged upon the rocks and shores, before proceeding far on their course, and they remain where they are deposited until the spring freshets occur, when the river-bed receives a thorough cleansing, and the sea swallows up the filth. A comparison of the Merrimack River waters with those of the English and Continental streams, upon which manufactories exist, gives the following results:—

	Total solids in 1,000,000 parts.	Organic.
Merrimack	60.	30.
Thames at London Bridge	408.4	100.
" " Chelsea	304.	34.
Clyde above Glasgow	116.1	26.1
Rhine at Strasburg	169.4	3.3
Penk near Wolverhampton	325.	68.6
Hawswater, Cumberland	57.	9.

It will be noticed that the amount of organic matter found in the Merrimack is exceeded only by three of the streams in the list, while the amount of solid matter is less than any, with one exception.

HARDENING COPPER.

MR. WENDELL PHILLIPS has so often delivered his lecture upon the "Lost Arts" in New England, that almost every one, young and old, is familiar with its statements. Many of these do not bear a very close examination and investigation, but still the lecture is an interesting one, and much more useful than the trashy performances of the fashionable lecturers of the day. Among the many arts and processes of the ancients which he considers as lost to the modern world is that of hardening copper so that it will form cutting instruments, and serve all the purposes to which steel is applied. Undoubtedly there is great exaggeration in the statements made regarding the hardening of copper by the Egyptians and Romans, but it is probable they did succeed in making some very useful implements from the metal. The art of hardening copper is not however a "lost art," for it is known that where phosphorus is combined with it, its physical character is so far changed that it becomes very hard. Berzelius succeeded in making a penknife blade of copper and phosphorus, so hard that it carried a fine cutting edge, and he used it for the purposes of an ordinary steel knife. But it is a curious and perhaps

instructive fact that this alloy is not stable, but easily oxidizes, and in a short time crumbles and falls into a powder.

It is quite probable the copper of the ancients was hardened in this way, although they were totally unacquainted with the element phosphorus. They might have learned that bones contained an element that gave to copper peculiar properties, and still have had no knowledge of the nature of the substance. They might have made a mixture of bone dust, charcoal, and copper, and this mixture exposed to the influence of heat would form the alloy desired. As zinc was a metal unknown to them, they may have employed a process analagous to this in making an alloy in some respects corresponding with our brass. Extended experiments have been made in modern times to form alloys of this nature, but we do not specially need them. Steel is much cheaper and better, and so long as we have an abundance of this compound of carbon and iron, we can appropriate our copper to other and more valuable uses. The ancients in their metallurgical operations as well as in all other labors, worked in the dark, and whilst they were fortunate enough to stumble upon some important processes, they were far from attaining to the perfection to which we have arrived. We work in the light of exact science, and our methods are the results of study and knowledge which have the advantage of mathematical exactness. If the ancients used phosphorus to harden copper, the rapid oxidation of the compound would account for the disappearance of every tool or implement of the kind.

PLANT FOOD.

Dr. Hoskins, the able editor of the *Vermont Farmer*, believes that sorrel has the power of decomposing feldspathic rocks through the agency of oxalic acid, which it holds as a constituent. The Doctor's industry in hunting up authorities to support his views is to be commended; but it is a hard point to prove that oxalic acid, in or out of connection with plants, will act upon "solid feldspar sand" and decompose it. If a plant elaborates oxalic acid, it is simply oxalic acid, and it must behave in the presence of other bodies as it does when produced from other sources. It does not matter from whence it comes, and inasmuch as "solid feldspar sand" is totally insoluble in oxalic acid, it cannot "dissolve out any potash to supply its wants." This is one point in our criticism in the November number of the Journal; the other was, that plants have not the power to prepare their own food. If this is not an axiom in vegetable chemistry, we must go back to the period when research began, and commence study on a new basis. The opposite view is contrary to analogy and facts, and the quotation from Prof. Johnson do not, when carefully considered, support such hypothesis. Liebig's statement regarding the action of rootlets upon limestone pebbles does not afford satisfactory proof that the decomposition results from the labors of the plant to secure food, since the same furrowing occurs upon iron aqueduct pipes when the roots of trees twine about them. The mere contact of vegetable substances, living or dead, with limestone, above ground or below, will, under certain conditions, serve to promote decomposition. This is seen in marble tombstones, old marble buildings, and in limestone boulders. The cryptogamic plants found upon our planet, and to the existence of which all life is due, are presumed to have originated from seeds or germinal principles, and so have the lichens which live and thrive upon bare rocks. Have the little germs the power of manufacturing their inorganic food from the refractory rocks to which they cling? No. How then do they secure their food? The answer is obvious. Every rock exposed to rains, air, and sunshine is constantly subjected to decomposing influences. There is a trace of nitric acid brought in contact with rocks by rain water, which probably results from decomposition of air by electrical agency; this acts upon rock surfaces. Water itself has solvent powers; carbonic acid, always present in air, is an active decomposing agent, and moreover, the fact is established that all rocks, however bare they may appear to be, have *indeed a thin covering of dust*, sufficient in amount to afford ample nourishment to the low forms of plant life. The Creator has provided forces whose especial work it is to prepare inorganic food, so that it can be taken up by water and carried into plant structures, but he has not conferred upon plants the capability of dissolving and preparing their own food.

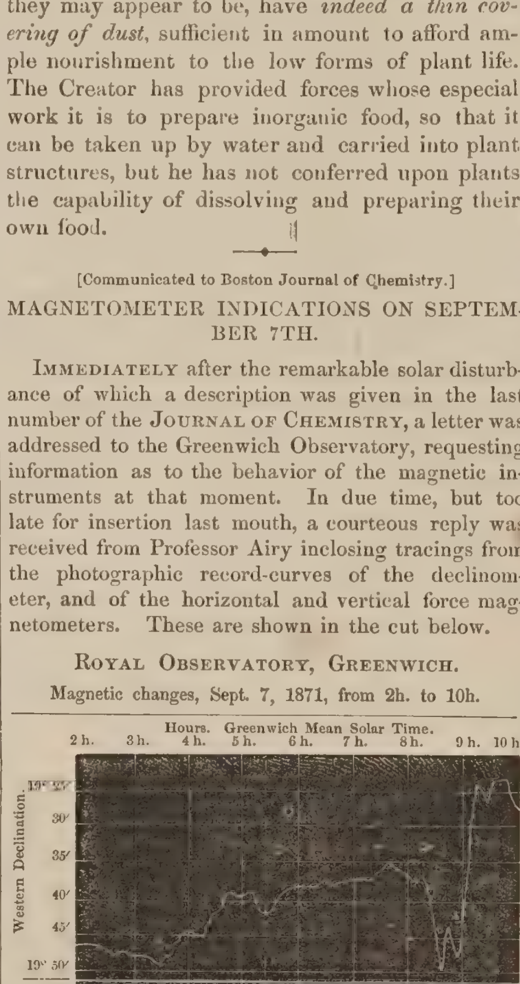
[Communicated to Boston Journal of Chemistry.]

MAGNETOMETER INDICATIONS ON SEPTEMBER 7TH.

Immediately after the remarkable solar disturbance of which a description was given in the last number of the Journal of Chemistry, a letter was addressed to the Greenwich Observatory, requesting information as to the behavior of the magnetic instruments at that moment. In due time, but too late for insertion last mouth, a courteous reply was received from Professor Airy inclosing tracings from the photographic record-curves of the declinometer, and of the horizontal and vertical force magnetometers. These are shown in the cut below.

Royal Observatory, Greenwich.

Magnetic changes, Sept. 7, 1871, from 2h. to 10h.



The vertical dotted line indicates the probable time of the explosion, 12h. 40m. Hanover Time.

Contrary to my expectation there was no specially marked disturbance of the magnets *simultaneous* with the "explosion" (if explosion it really was). It is not impossible that the small disturbances indicated on the first and second curves were really caused by it.

Professor Airy writes: "The day was one of magnetic disturbance, but it does not appear that any remarkable movement coincided with the beginning of your observation. There was a sudden movement nearly at the end."

About $2\frac{1}{2}$ hours after the "explosion" the magnetic storm began which developed into the beautiful Aurora of that evening.

It would seem accordingly either that considerable time is occupied in transmitting a magnetic perturbation from the sun to the earth; or else, what is perhaps more probable, that mere *mechanical* movements in the solar atmosphere, such as the phenomenon in question appears to have been, are less efficacious in disturbing our magnetometers than certain other actions which are less conspicuous.

While there can be no possible doubt that there is a close connection between the condition of the solar surface and magnetic disturbances on the earth, much further investigation will be required to elucidate the matter. C. A. Young.

Hanover, *Nov.* 14, 1871.

RAILWAY DUST.

A friend has sent us a copy of the Manchester (Eng.) *Guardian*, for October 8, 1871, in which we find a full report of the last meeting of the Manchester Literary and Philosophical Society. Among the papers read was one by Mr. J. Sidebotham on the microscopic examination of railway dust, which will, we think, be interesting to the readers of the Journal, and we therefore give the following abstract of it:—

While travelling by rail between Saltley and Camp Hill, I spread a paper on a seat of the carriage near the open window, and collected the dust that fell upon it. A rough examination of this with the two thirds power showed a large proportion of fragments of iron; and on applying a soft iron needle I found that many of them were highly magnetic. They were mostly long, thin, and straight, the largest being about $\frac{1}{150}$ of an inch, and, under the power used, had the appearance of a quantity of old nails. I then, with a magnet, separated the iron from the other particles. The weight altogether of the dust collected was 5.7 grains, and the proportion of those particles composed wholly or in part of iron was 2.9 grains, or more than one half. The iron thus separated consisted chiefly of fused particles of dross or burned iron, like "clinkers;" many were more or less spherical, like those from the flue of a furnace, but none so smooth; all were more or less covered with spikes and excrescences, some having long tails like the old "Prince Rupert's drops;" there were also many small angular particles like cast iron, having crystalline structure. The rest of the dust consisted largely of cinders, very bright angular fragments of glass or quartz, a few bits of yellow metal, opaque white and spherical bodies, grains of sand, a few bits of coal, etc. After the examination of this dust, I could easily understand why it had produced such irritation; the number of angular, pointed, and spiked pieces of iron, and the scoriæ or clinkers, being quite sufficient to account for the unpleasant effect. I think it probable that the magnetic strips of iron are laminæ from the rails and tires of the wheels, and the other iron particles portions of fused metal, either from the coal or from the furnace bars. The large proportion of iron found in the dust is probably owing to the metal being heavier than the ordinary dust, and accumulating in cuttings such as those between the two stations named. If I had to travel much by railway through that district, I should like to wear magnetic railway spectacles, and a magnetic respirator in dry weather.

EDITORIAL NOTES.

THE METEOROLOGY OF OCTOBER. — According to the report of Professor Loomis, of Yale College, the mean temperature of the month, at New Haven, was 53.3 degrees, which is 2.2 degrees above the average temperature of this month. The highest temperature of the month was 73.2 degrees on the 15th; the lowest was 28.5 degrees on the 21st. The range of the thermometer for the month was 44.7 degrees, which is a little less than the usual range. The first frost of the season occurred on the morning of September 21st, and the first ice occurred on the morning of October 21st.

The amount of rain for the month was 5.47 inches, which is nearly two inches more than the average fall. The amount of rain for the past twelve months has been 44.54 inches, which is exactly the average fall at New Haven deduced from observations of twenty-nine years.

DARWINISM. — An able article on this subject, from the pen of Mr. Chauncey Wright, of Cambridge, appeared in the *North American Review* for July, under the form of a review of Mivart's "Genesis of Species," the arguments of which were effectively answered. Mr. Darwin was so much pleased with the article that he obtained the permission of the publishers to reprint it in a pamphlet for distribution among men of science interested in the subject. The fact that Mr. Darwin appears to consider it the best reply that has yet been made to the opponents of his theory of evolution is likely to draw increased attention to the article in this country.

THE SEA SERPENT IN IRISH WATERS. — Our old friend, the sea serpent, has led a retired life for several years. Since he used to pay his occasional visits to Nahant, in the palmy days of that marine resort, we have heard no authentic news of him until within a month or two. The *Limerick Chronicle* informs us that he has now appeared on that side of the Atlantic, in the beautiful bay of Kilkee. A party of several ladies and gentlemen, one of whom, fortunately for the serpent, is "a well-known clergyman in the north of Ireland," saw an enormous head, shaped somewhat like that of a horse, emerge from the water. Behind the head and on the neck was a kind of chignon, or "huge mane of seaweed-looking hair, which rose and fell with the motion of the water." The *Chronicle* adds that "one lady nearly fainted at the sight, and all had their nerves considerably upset by the dreadful appearance of this extraordinary creature." The well-known clergyman, however, was equal to the occasion, for he minutely inspected the interesting monster, watching it, until after a few minutes the gigantic head ducked and disappeared beneath the waters. An English paper, commenting upon this Hibernian piece of intelligence, remarks that the serpent has probably "turned over a new leaf, and will in future make himself at home at various seaside places; nor can anything be more injudicious than to turn a cold shoulder upon him; or annoy him, on the other hand, by vulgar curiosity. He is evidently a most determined beast, of gigantic strength and stature, and it would be well, now that he shows a social tendency, to meet him respectfully but with self-possession. His appearance, it is true, is against him, but, for aught we know, his disposition may be good; and so far from there being any reason for ladies to faint away when he puts his head out of the water, there is, it is to be feared, far more reason to expect that the serpent himself will be overcome by faintness at some of the sights to be witnessed at many of the watering-places on our coast."

THE SCHOOLMASTER ABROAD IN ENGLAND. — The *Pall Mall Gazette* states that the following was one of the applications lately received by the Stafford School Board for the office of clerk: —

Septr 203, 1871

Sir i see in the Stafford paper a advertizement for a clerk to the school board I should be willing to Take the Sittuaction at 50 a year i am Not a Member of the Legal porfission i should be abel to Give all My time the Dutys of the office i Coud take to it at Once if I was Ellectd i have had a Good Eaducation this is my Own Handwriting i ham 305 years of age and I can have a Good Carachter I have Been employed on the Railway but I have left has I think i am Abel to take a Better Sittiation And i think the office would Suit Me very well plese let me no if i shall have to Come to stafford or wheather this will Be Suffischiant By Doing so yo will oblidge Sir Your most Obedient Servent, J—— J——

PHOTOGRAPHIC PROPERTIES OF COPPER SALTS. — In an article on this subject in the *Philadelphia Photographer*, Dr. Sellack announces an interesting discovery. He has found that the iodide and bromide of copper have the property of photographic development, like the salts of silver. "A plate of pure copper, iodized or bromized as in Daguerre's process and exposed in the camera, develops a picture in mercurial vapors. Also when the bromized or iodized copper plate is sufficiently exposed under a photographic negative, a picture is produced which can be fixed by hyposulphite. The sensitive copper plate, therefore, acts exactly like the Daguerrean plate. A process similar to the wet collodion process is impracticable with the salts of copper on account of their solubility in water." There is reason to believe, however, that these salts will prove more sensitive to the different colors than the silver salts, and the discovery may prove to have important bearings upon the photography of the future.

REMARKABLE STATEMENTS. — A popular journal after giving an item in regard to the sinking of the bottom of the Morris and Essex Canal near Broadway, New Jersey, comments on it as follows: —

"It is supposed that the lime in the limestone rock of which the ground under the canal in that region is composed, has been secretly burning for years by 'spontaneous combustion' and thus left an immense hollow underneath. The trickling of water through lime rock will set it on fire."

We have frequently heard of "burning limestone," but never suspected that it was liable to ignite from water contact. The information that water trickling through lime rock will set it on fire is certainly new. Water holding carbonic acid in solution will dissolve limestone, and in this way immense caves are formed. The Mammoth Cave of Kentucky is one of the best known and largest of these caverns, but every limestone region abounds in them. Occasionally the roof of a cave becomes too thin to bear the superincumbent earth, and a portion of it falls in, forming the well known "sink holes" of limestone regions. When one of these sink holes happens to be formed in the bed of a creek, the water of course runs into it, and if the cave has no outlet at a lower level, it forms a deep pond. But those caves almost always do have an outlet and the creek disappears, to appear again perhaps miles away. Instances of this kind are frequent through the limestone regions of the West.

A NEW WATER RAM. — If what is stated regarding a water ram, by a writer in the *American Agriculturalist*, is true, perpetual motion is certainly discovered. He says, "A No. 5 ram would, with a fall of three or four feet, use seven gallons of water per minute, elevating about half that quantity to a height of fifty or a hundred feet;" or, in other words, one gallon of water descending four feet would raise one gallon of water twenty-five feet. The very best water-wheels will not raise over 95 per cent. of the water to the same height from which it descended, and therefore we may be allowed to express doubts in regard to the above, especially as rams heretofore used utilize only about one half of the power developed by the fall of water. From 60 to 65 per cent. is the most that has ever been claimed for the best forms of the apparatus.

MICROPHOTOGRAPHY. — Apropos of this subject, on which Mr. Stodder has an interesting article in this number of the JOURNAL, the *British Journal of Photography* says that the process is becoming so perfect and so inexpensive that "we may soon have our daily paper of the size of a postage-stamp, and carry our favorite poets in our vest-buttons. We shall see 'a new edition of Macaulay complete in three shirt-studs,' or, 'the tiny edition of Dickens' complete in two sleeve-buttons. Every one will then carry a microscope as we now do a penknife."

ATOMS.

THE British War Department is about to appoint a committee of practical and scientific men to inquire into the manufacture and uses of gun-cotton and other explosive compounds, and their employment for artillery and in mining. — That curious work of ancient art, the "Bayeux tapestry," said to have been wrought by the hands of Matilda, queen of William the Conqueror, is to be reproduced for next year's International Exhibition at London, the reproduction to be half the size of the original, or large enough to show every thread and every mending; and a few copies will be printed of the full size (218 feet long by 19 inches wide) and colored in fac-simile. — A colossal bronze statue of Franklin, twelve feet and a half high, and standing on a pedestal fourteen feet high, is to be erected i. Printing House Square, New York; and the ceremony of unveiling will take place on the anniversary of Franklin's birthday, the 17th of January next. — A fine yacht was lately burned to the water's edge, off Montauk Point, Long Island, from the explosion of a pintle lamp filled with kerosene; in other words, another instance of "cheap naphtha used to adulterate or to substitute the more costly oil of safe character, and lives lost and property destroyed in order that some scoundrel could make five, ten, or twenty cents more on the gallon of illuminating liquid sold in his shop." — Speaking of kerosene, it has been proposed to invite the woman whose cow kicked over the lamp that kindled the Chicago fire to lecture on the danger of using cheap burning fluids, and she would undoubtedly "draw well." — The Collins steamer *Adriatic*, once renowned for her magnificent fittings and her high speed, after lying for some years in the Birkenhead docks opposite Liverpool, has been rigged as a ship, and has sailed from the Mersey for Rio Janeiro, with a cargo of 3,800 tons of coal. — Salmon from the Sacramento River, in California, are now sent eastward in large quantities, the fish being a drug in the home market. — At Spernberg, near Berlin, a deposit of rock salt was discovered, whose thickness, so far, has been found to exceed 2,962 feet, and whose horizontal extension seems to be equally great; and near Segeberg, in Holstein, another deposit has been discovered, which promises to be of similar magnitude. — A Philadelphia paper states that in that city there are eight thousand establishments in which persons are employed in productive or manufacturing industry, and the value of their products for the current year cannot be less than three hundred and fifty millions of dollars; and eighteen hundred of these factories are driven by steam-engines, whose aggregate power is that of fifty thousand horses. — The ivory keys to pianos or melodeons, when yellow, may be rendered white again by sponging them with diluted sulphurous acid and exposure to the sun. — An exchange says that "Some inconsiderate persons have recently developed a fine vein of coal near Corning, N. Y., a locality the geologists have repeatedly declared it

impossible for coal to exist in, and the indignant *savants* are contemplating an injunction." — According to *Dingler's Polytechnic Journal*, alcoholic solutions of perchloride of iron are not precipitated by carbonate of lime, and may therefore be applied to white marble for the purpose of imparting to it a yellow color; the depth of the color will depend on the degree of concentration given to the solution. — Everybody remembers Coleridge's epigram, in which he asks "what power divine" will suffice to "wash the river Rhine" after that stream has washed the unfragrant city of Cologne; and this very question seems now to be agitated, for sanitary reasons, by those who have to use the water, which has become so contaminated with sewage that measures must be taken for its purification. — The fact that horses and other animals with broken limbs do not appear to lose their appetites, has led some scientific men to raise the question whether these creatures suffer as much under the circumstances as men do; for a man could not sit quietly down to dinner just after breaking his leg. — *The American Builder*, though utterly burned out by the Chicago fire, issues its November number only a few days late, and in the same excellent style as usual, except that it has no engravings; and it promises its patrons that its next number shall be fully up to its established reputation in every respect. — The *New York Times* devotes more than a column to a review of Rolfe's editions of *The Merchant of Venice* and *The Tempest*, in the course of which it remarks that "the work has been done so well that it could hardly have been done better," and that "it shows throughout knowledge, taste, discriminating judgment, and what is rarer and of yet higher value, a sympathetic appreciation of the poet's moods and purposes." — The postal telegraph system appears to be working very successfully in Great Britain.

RESONANCE. — The experiment on *resonance* mentioned in the JOURNAL OF CHEMISTRY for March, can be very prettily made by connecting two glass jars containing water by means of a short flexible tube acting as a siphon. If one of the jars be raised or lowered, the water will rise or fall in the other jar, and the length of the column of air which gives the loudest note when the vibrating fork is held over it can be marked by pasting a slip of paper on the jar. If a few drops of red ink be put in the water, the rise and fall of the note corresponding to the length of the column of air may be made perceptible to a large class. If one of the jars be set on a stand and the other held in the hand of the experimenter, it requires but one person to make the experiment. H. T.

GREENE SPRINGS, ALA.

LITERARY NOTES.

A NEW issue in Mr. Baird's excellent series of works on industrial science is *The Manufacture of Russian Sheet Iron*, by John Percy, M. D., F. R. S., with Illustrations and an Appendix on American Sheet Iron. This little book, which is sold for fifty cents, is prepared by one who is an authority on all matters relating to metallurgy, and it has a special interest as treating of a subject which has long been a great mystery.

The Harpers have reprinted M. Reclus's *The Earth*, with all the maps and illustrations, at half the price for which the English edition has been selling quite largely in this country. They have published many popular scientific books, but no one on the list can take a higher rank than this. The author, as the London *Examiner* remarks, "drawing useful and instructive information from the great scientific writers of every age and every country, has endeavored to place before his readers a full and complete account of the globe which we inhabit, of its past history, its present condition, and its probable future; and he has succeeded admirably."

The "Student's Series" of historical manuals, published by the same house, is true to its name, being precisely adapted to the wants of the student in school or college. The *Student's Ancient History of the East*, just issued, is a welcome addition to the list. An abridgment of *Hallam's Middle Ages* is announced as soon to follow.

Henry the Eighth, with notes and illustrations, the third of Mr. Rolfe's series of select plays of Shakespeare, will be published in a few weeks.

Medicine.

☞ *In admitting to our columns communications from respectable sources, we must not be considered as endorsing the views or statements of the articles.*

MEDICAL PHILOSOPHY.

UNDER the above heading in the November number of your excellent journal appeared an article which may be embodied in the following propositions:

1. The regular profession has no comprehensive system of medical philosophy.

2. In the human organism there is no provision for the elimination of mineral substances foreign to it.

3. Therefore we should administer such mineral substances, and such only, as enter into the composition of the body.

In reply: 1. We certainly have a "comprehensive" but not a sweeping medical philosophy, and may the kindly shades of the God and of the Father of Medicine ever preserve us from the latter!

We have theories of healthy and diseased functions; theories for the genesis of the various diseases; theories for the "action of medicines;" line upon line and precept upon precept; indeed our works on physiology, pathology, practice, and materia medica are built on a well digested and comprehensive medical philosophy. Virchow, Paget, Headland, Wood, and numerous others fully vindicate our claim to such a philosophy.

2. There is — in the human organism — provision for the elimination of mineral substances foreign to it. Thus mercury passes out by the "liver, salivary glands, and skin;" zinc by the kidneys and liver; the mineral acids are variously eliminated; some salts pass out by the kidneys, others by the bowels, producing, respectively, diuresis and catharsis. "All those medicines must be secreted which have nothing in the natural blood to correspond to them." (Headland on the Action of Medicines, page 310.)

3. Experience (the one and only lamp by which our feet should be guided) disproves the truth of this dogma, which is evidently founded on the erroneous postulate that we invariably exhibit medicines for the purpose of correcting a deficiency of the normal tissue ingredients. Many of the diseases we have to contend with are functional and not organic; there is neither deficiency nor redundance, only deranged action of tissue elements. The homœopath reels under his burden of "similia similibus;" the allopath finds difficult sailing with his "contraria contrariis;" shall we, too, abandon our old and faithful monitor, experience?

WALLACE A. BRIGGS, M. D.

GENEVA, OHIO.

THE HOSPITAL AND MEDICAL SCHOOL OF VIENNA.

THE *American Practitioner* for October contains an interesting account of the Vienna Hospital and School, from the pen of Dr. Melvin Rhorer. It appears that the number of American students in Vienna is rapidly increasing; it being sixty at present, or more than fourfold what it was two years ago. This is not owing so much to the interruption of medical teaching in Paris on account of the war, as to the fact that French medicine seems to be declining, and even if there had been no war the other European universities would have drawn many foreigners away from the French capital.

Dr. Rhorer advises the student to get his elementary instruction at home. Our modes of teaching are, in his judgment, superior, or at least better adapted to our wants — to say nothing of the fact that seven years would be required for the purpose by the Vienna *curriculum*. It is for clinical instruction that the student goes thither, and nowhere can he find greater advantages in that department. In London and Paris the student is bewildered with a dozen hospitals and schools; and clinics are held at so nearly the same hour, and at places so far apart, that it is almost impossible to attend more than one or two during the same day. In Vienna, on the other hand, everything is centralized in the Imperial Hospital; and one may work from sunrise to sunset without loss of time.

The hospital was founded in 1787 by the Emperor Francis Joseph II., and covers an area of ten acres or more. It is two and a half stories high, with walls of brick, rough cast, and windows and doors of the plainest pattern. An arched gateway leads into the large court, containing about three acres, tastefully laid out with shade-trees, flowers, walks, and fountains. There are eight other courts connected with this, and at the end of the last court stands the pathological institute, which was erected by Rokitansky in 1859. This contains the dead-house, the lecture-room for chemistry and materia medica, and the various operating-rooms. To the right of this, on a hill, stands the building for the insane, which is a large round tower with narrow windows, and shut off from the rest of the world by a moat. The wards of the hospital are constructed in the simplest manner; scrupulously clean, but with no attempt whatever at embellishment. Their number is one hundred and ten, and they contain twenty-five hundred beds. There are also thirty clinical amphitheatres, the apartments for the various officers, and a chapel. "There are seemingly no modern conveniences about the hospital. The heating is done by stoves, and the water taken to the wards by the convalescents from the fountains in the courts."

The diet of the hospital and also the medicines used are supplied entirely by contract. About thirty cents per day is the cost of maintaining a patient in the public wards; but there also are private wards of various classes for those who can afford to pay more. An inhabitant of Vienna pays twenty cents per diem, a foreigner double that amount.

About twenty thousand patients are admitted annually, besides those in the lying-in wards. From eight to ten thousand children are born in the hospital during the year, about fifty per cent. of whom die in infancy. Those that live, and are not claimed by their parents, are either put into the army or assigned to other government work.

Of the teaching force, and the facilities for instruction, Dr. Rhorer says: —

"The faculty of medicine in the University of Vienna, although it has recently lost in Skoda and Oppholzer two of its greatest lights, is still filled generally by men of world-wide reputation. In fact, only from such men has the choice been originally made. There is no such thing as promotion by seniority, and a Viennese reputation alone is by no means sufficient. Bilroth made his name at Zurich, and was called here from Berlin. In most of the departments there are two separate chairs for each branch. Each professor has lectures in a different amphitheatre, and issues his own tickets, which students take or not as they wish. Of course the most popular teachers have the largest classes. Bilroth and Dumreicher are the surgeons Braun and Spät the obstetricians and gynæcologists, while

Hebra and Neuman hold the chairs of dermatology. Sigmund and Zeisel lecture on syphilis, Jäeger on the eye, and Rokitansky on pathological anatomy. The teaching by this brilliant array of professors is wholly clinical. The cases for illustration are seemingly without number. The greatest difficulty with the foreign student lies in the lectures being given in a strange tongue. If he has come unacquainted with the German, several months will necessarily be consumed in acquiring a sufficient familiarity with the language to follow the courses. . . .

Excellent as is the faculty and splendid the clinics, it is from the assistants that the most practical lessons are obtained. They teach everything. The bulletin-board at the University gate is crowded with the announcements of their courses — on the eye, the chest, the ear, on stricture, electro-therapy, minor and operative surgery, operative midwifery, etc."

SMALL-POX.

This loathsome disease made its appearance in several of our cities and large towns during the past summer, and many cases, both of confluent small-pox and of varioloid, were reported. In the city of Lowell it raged for several months, and many deaths occurred from it. A strange feeling has been engendered in England, and to some extent in this country, against vaccination, which is a most unjust and absurd prejudice. It is born of ignorance and vulgar conceit, and where it exists, small-pox will exist. The authorities in all cases should insist upon thorough vaccination in communities where the disease prevails. The following instructions for controlling small-pox contagion, enforced at Lowell, proved effective in arresting the spread of the disease : —

ISOLATION.

1. Persons attacked with small-pox or varioloid, and all infected clothing of the same, must be immediately separated from all other persons liable to contract or communicate the disease.

2. Nurses and the infected clothing of such persons must be treated as in quarantine.

3. None but nurses, and the attending physicians, will be allowed access to persons sick with small-pox or varioloid.

4. Patients must not leave the premises until they, together with the bedding and clothing, have been disinfected, and permission given by some physician of the Board of Health.

DISINFECTION.

1. All bedding and personal clothing infected with the small-pox contagion, which can, without injury, must be washed in boiling water.

2. Infected feather-beds, pillows, and hair mattresses must have contents taken out and thoroughly fumigated, and ticks washed in boiling water.

3. Infected straw and excelsior mattresses must have contents removed and buried, and ticks washed in boiling water.

4. Infected blankets, sheets, and pillow-cases, and all articles in contact with, or used by the patient, must be washed in boiling water.

5. Personal clothing and bedding, particularly comforters, which cannot be wet without injury, must be disinfected by baking or by fumigation.

6. Instead of using boiling water as the disinfectant, the following chemical process with cold water may sometimes be conveniently substituted : Dissolve in a wash-tub, containing eight gallons of cold water, one pound of the hyposulphite of soda, immerse all the articles of clothing and bedding used by or around the patient, and when thoroughly saturated add half a pint of sulphuric acid, first diluting it with one gallon of water; stir the whole and allow the clothes to soak an hour, then wring them out, rinse three times in cold water, and hang out to dry.

7. Disinfection of houses, clothing, and bedding by fumigation may be effected by filling the closed rooms with the fumes of sulphurous acid, or of chlorine gas. The first can be accomplished by putting half a pound of sulphur in an iron dish, pouring on a little alchohol and igniting it, thereby causing the sulphur to burn and give off sulphurous acid fumes. The second can be accomplished by moistening with water four pounds of chloride of lime, contained in an earthen or wooden vessel, and adding thereto a pint of muriatic acid, to liberate the chlorine gas. Clothing and bedding, to be well fumigated, must be separated as much as possible, and hung upon the walls and furniture of the room, so that everything will be thoroughly permeated. The rooms should be kept closed an hour or two after being charged with gas by either method, and then thoroughly ventilated. No attempt should be made to fumigate the sick-room in this manner, while it is occupied by the patient.

8. On the recovery, removal, or death of every case of small-pox or varioloid, the clothing, bedding, and premises will be disinfected, in accordance with the above rules, under the direction of one or more physicians employed for the purpose by the Board of Health

9. The physicians employed in disinfecting may cause the removal, destruction, or burial of such infected bedding and clothing as may, in their judgment, seem to require it, of which they shall keep a correct record, with date, kind of article, whether new or old, estimated value, name and residence of the owner. No person shall burn any contagioned articles unless authorized by the Board of Health.

10. The sick-room should be kept well ventilated, with such precautions as not to expose the patient to direct currents of air, and should be occasionally fumigated, slightly, by throwing upon a heated surface a few teaspoonfuls of a *solution of carbolic acid*, made by dissolving one ounce of crystallized carbolic acid in a quart of rain water. Pieces of cloth may be soaked in this solution, and suspended in the room, also in the hall-ways adjoining. All vessels for receiving discharges of any kind from patients, must be emptied immediately after use, and cleansed with boiling water. When convalescence has taken place, the patient must be thoroughly washed in warm water and soap, and put on fresh, clean clothes throughout.

11. Privies, water-closets, garbage-tubs, water-pipes, and all kinds of drains and foul places in houses, stables, and yards, may be disinfected with a solution made as follows : Dissolve eight pounds of copperas (sulphate of iron) in five gallons of water, add one quart of the solution of carbolic acid, and mix well.

12. It should be remembered that there are no substitutes for pure air and water. Let fresh air and sunlight purify every place they can reach; open and dry all cellars; keep the grounds about dwellings dry and clean, and let personal and domestic cleanliness be everywhere observed.

Vaccination, and re-vaccination, is of paramount importance, affording the best attainable protection against small-pox, and mitigating its severity when not preventing an attack.

LACTO-PHOSPHATE OF LIME.

We are indebted to Prof. B. W. McCready for the following note on the lacto-phosphate of lime : —

There are strong grounds for the belief that, besides being a necessary ingredient of the hard parts of vertebrated animals, the phosphate of lime is intimately connected with the process of cell-formation. According to Lehmann, it is found in appreciable quantity wherever cells or fibres are formed, even in those inferior animals in the hard parts of which the phosphate is replaced by the carbonate of lime; it is more abundant in the plastic secretions from wounds than in the serum of the blood; it is less abundant in the venous blood derived from parts, as the muscles, in which the metamorphosis of tissue is greatest, than in that coming from parts of inferior vital activity.

The phosphate of lime has been recommended in various forms of imperfect or depraved nutrition, particularly in cases of rickets; and the experiments of Milne Edwards seem to show that, under its use, fractured bones in dogs and rabbits show a quicker and more abundant formation of callus. It however has never obtained the general confidence of the profession. In a series of articles in the *Archives Générales de Médecine*, for December, 1869, and for January and February, 1870, Dr. L. Dusart reviews the whole subject, and, attributing the unsatisfactory results heretofore obtained to the great insolubility of the ordinary phosphate, recommends the use of a new preparation, which he terms the lacto-phosphate of lime, in which the lime-salt is dissolved in free lactic acid.

M. Dusart finds — 1. That the lacto-phosphate of lime injected through a fistulous opening into the stomach of a dog, during digestion, is not precipitated by the contents of the stomach, but remains dissolved in the chyme.

2. That in comparative experiments made on guinea-pigs, in which the bones of one of the extremities were fractured, that in the animals submitted to the action of the lacto-phosphated lime, the callus was more voluminous, and the consolidation of the bone more perfect, than in those submitted to a similar regimen, with the exception of the lime-salt.

3. In four cases of tardy union of bone observed in the Hôpital Beaujon, the administration of the lacto-phosphate was attended with marked improvement of the fractured part; in three of the patients, the appetite was at the same time greatly increased.

4. In a number of cases of rachitis, the influence of the lacto-phosphate was well-marked, the children rapidly improving under its administration, the appetite at the same time being greatly increased.

5. Several cases of diarrhœa and indigestion, after resisting other treatment, quickly yielded to the influence of the lacto-phosphate.

At my request, Mr. W. Neergaard, pharmaceutist, prepared for me, in June last, a syrup, by dissolving recently-precipitated phosphate of lime in concentrated lactic acid, and then adding a convenient amount of syrup. I have found it useful —

1. In cases of defective nutrition, with or without diarrhœa, but without any acute disease of the alimentary canal, particularly when these conditions have occurred in prematurely weaned children.

2. In rachitis.

3. In atonic dyspepsia. In most of these cases, not only were the digestive power and nutrition of the patient greatly improved, but the appetite for food was augmented, sometimes to an extraordinary degree. Dr. William A. Hammond has found it of very great value in cases of nervous derangement, attended with impaired nutrition; and Dr. Barstow, of Sandford Hall, has used it largely in similar cases. It is very probable that the free lactic acid may, in many instances, contribute greatly to the efficiency of the preparation.

In forming the syrup of the lacto-phosphate, Mr. Neergaard obtains the phosphate of lime, according to the United States Pharmacopœia, by acting on bone earth with muriatic acid, and precipitating the dissolved phosphate with ammonia. He saturates an ounce of concentrated lactic acid with the recent precipitate, and to the clear solution he adds six

ounces and a half of water, an ounce and a half of orange-flower water, and twelve ounces of sugar. Prepared in this manner, the syrup will contain from fifteen to twenty grains of phosphate of lime to the ounce. The variation in strength is caused by the want of uniformity in the strength of the lactic acid; that furnished by the best manufacturer — Merck, of Darmstadt — varying considerably in its degrees of concentration. The dose for a young child is one to two drachms three or four times a day, while an adult may take a tablespoonful frequently. The taste is pleasantly acid, and the syrup is not apt to disagree even with delicate stomachs. — *N. Y. Med. Jour.*

Note.— Messrs. J. R. Nichols & Co., chemists, prepare the syrup of the lacto-phosphate of lime of standard strength, and physicians and dealers can procure it of them.

MEDICAL MEMORANDA.

The Physician's Office. — The following is an extract from Professor McGraw's address to the last graduating class, at the Detroit Medical College: "I have been in doctors' offices where a skull grinned from one corner, ghastly anatomical plates hung from the walls, and splints, suggestive of broken bones, were placed conspicuously in every corner. What a delightful resting-place for a sick woman,— visions of death, disease, and injury greeting her on every side! Now, gentlemen, make your offices pictures of comfort and cheerfulness. Banish from them every sign of your professional occupation, so that your patients may enter them not only without disgust, but with actual elevation of heart. I think I need hardly say that your apartments should be scrupulously clean, although I can recollect too many rooms, occupied by physicians, whose windows were festooned with cobwebs and dried flies, and whose floors were stained with tobacco spit. I have been pleased sometimes to hear the occupants of such offices groan about the lack of custom, for if it is the duty of a physician to preach the virtue of cleanliness, he should himself be a living example of his own doctrine. Filthiness in a physician is like dishonesty in a merchant, the very worst of sins."

Humbug in Holy Garb. — The *Scientific Press*, of San Francisco, says: "A certain 'Reverend' advertises to send free, out of pure kindness, a valuable receipt for the cure of consumption, to all who forward to his address a postage stamp. This looks fair, but the readers of a thousand journals wonder how he can afford to pay, year after year, for so many advertisements. The mystery is unravelled when a cunning circular is returned with the receipt, saying the only safety in procuring the wonderful South American remedy is by sending $3.50 to the 'grateful' scoundrel 'snatched from the borders of the grave' who employs the title of Rev. to steal more successfully from 'gulls' who are silly enough to notice advertisements that promise to give 'something for nothing.' This is our answer to those who wish to make our advertising columns accessory to their despicable schemes."

The *London Medical Press* gives the following as a prescription for the "cure of consumption," coming from a clergyman in the West of England, reputed of great skill in diseases of the chest: "Isinglass, 1 oz.; eringo root, 1 oz.; garden snails, ½ pint; hartshorn shavings, ½ oz.; three dried vipers from Butler's, Covent Garden; 1½ pints water. Boil down to a pint."

The Spoon in Prescriptions. — A writer in the Canadian *Pharmaceutical Journal*, who appears to have investigated the subject very carefully, says that teaspoons have been gradually growing larger of late years, the spoon of the last century having been only about two thirds of the size of that in common use. He adds, however, that three sizes are made at the present time — large, medium, and small, containing 95, 85, and 60 minims respectively. Table-spoons also are larger, and vary from 4.5 to 6 fluid drachms in capacity. He infers that the dose of certain articles may be unsafe, if a teaspoonful or a tablespoonful be ordered, and proposes to abolish the dessert-spoon as a measure, substituting two teaspoonfuls. An exchange commenting on the article, says: "It is rarely, we apprehend, that more than a drachm is administered as a teaspoonful, or more than half an ounce as a tablespoonful. On the contrary, nine times in ten, an ounce mixture, when ordered in teaspoon doses, will afford more than eight doses, and an eight ounce mixture more than sixteen tablespoonfuls. Nurses seldom fill the spoon to its utmost capacity."

Patent Medicines in Russia. — A correspondent of the London *Chemist and Druggist* gives the regulations concerning the importation of patent and secret medicines established by the Russian Government. They are as follows: —

1. A petition has to be written on a (one rouble) stamped paper, to be sent free to the Manufacture and Foreign Commercial Department of the Finance Ministry (not to the Medical Department).

2. The exact composition of the remedy must be stated.

3. Only those remedies can be approved of by the Medical Council which have been examined and found useful by a foreign medical faculty, or any other scientific institution of equal standing.

4. The remedy should be so constituted that a long journey or time should not interfere with its properties.

5. It should not contain a decidedly poisonous substance.

6. Besides these regulations, it must require either difficultly obtainable apparatus and instruments for its preparation, or particular manipulation obtained only by long experience.

7. In reference to advertising it in the daily papers, leave has to be obtained from the newspaper censor.

8. All the cost of carriage, and other expenses connected with the remedy must be defrayed by the sender.

A Good Joke. — A capital burlesque appeared some time ago in the *Philadelphia Medical Times* under the title of "Microscopic Test-Objects," and some of the British medical journals have in all soberness taken it for granted that the American editor was the victim of a trick played upon him by some wag of a contributor. They actually plume themselves on detecting the "little game." One of them says that the article professes to be written "by a Dr. Neulenx, whose very name might have excited the editor's suspicions!" John Bull is proverbially slow to see a joke, but our readers will hardly believe that he could be blind to it in this instance, when we give an extract from the article in question. The following is one quoted by the astute critics over the water "as a fair sample of the whole:" —

"Having constructed a one-seventieth immersion objective on a new principle, having 191° aperture — the immersion liquid being fluoric acid — and, for illumination, having invented a new eccentric parallelopiped, to be used with fluorescent rays exclusively, some remarkable results have been obtained. I take great pleasure in stating that, with regard to test-objects, all previous observers have been totally wrong in every particular, and that *Pleurosigma angulatum* is, in the first place, constructed on the plan of the Nicholson pavement, and, in the second place, that it is not a pleurosigma at all. The most certain test-object is the *Neulensia difficilissima*, a very rare and remarkable diatom, in which my one-seventieth with the parallelopiped shows four kinds of beads and six sets of cross-lines, one of which se contains 147,229,073 lines to the inch: hence, l the well-known formula of Brewster, $\frac{dx}{du} = \surd \frac{\ }{o.x.p.}$ it is impossible that the undulations of light shoul pass without being previously deflagrated, an therefore no other lens can possibly show these line nor is it probable that this lens would with an other observer. The immense superiority of th test to Nobert's plate is apparent."

This, moreover, is not the first instance of th kind. A year or more ago, the *Boston Medical an Surgical Journal* published a burlesque article, b "A Surgeon in the United States Army," upon th medical value of the "ichthyocolla preparata Spa dingii" (in plain English, "Spalding's Prepare Glue"), which was seriously reviewed by the *Lo don Medical Press and Circular*, the critic sagel remarking that there are "far too many such prep arations in the American practice of medicine."

VALUABLE FORMULÆ.

To Administer Creosote. — As creos te i now frequently employed in the treatment of typhoi fever, and is exceedingly distasteful to some patients the *Canada Medical Journal* gives the followin formula which in great measure covers its flavor and is easily prepared: —

Creosote	3 drops;
Essence of lemon	2 drops;
Orange-flower water	1 ounce;
Spring water	3 ounces.

A spoonful to be taken at frequent interval throughout the day.

Cholera Pills. — A writer in *El Pabellon Medico* maintains that opium is as successful in cholera as quinine is in ague, and that it should be given in doses proportioned to the gravity of the case. He therefore has recourse to full doses of opium frequently repeated.

The following formula for cholera pills is that of M. Bourgone: —

Tannate of quinia	1 gramme;
Powdered opium	5 centigrs.;
Essence of aniseed	2 drops;
Simple syrup, to make	10 pills;

which may be taken in the course of one or two hours.

Salve for Chapped Lips and Hands. — Take two ounces of white wax, one ounce of spermaceti, four ounces of oil of almonds, two ounces of honey, quarter of an ounce of essence of bergamot, or any other scent. Melt the wax and spermaceti; then add the honey, and melt all together, and when hot, add the almond oil by degrees, stirring it till cold.

Tobacco in Certain Nerve-Diseases. — The *Doctor* says that M. Tamisier, in a recent French journal, states that, out of fifty-nine grave affections of the nerve-centres observed from 1860 to 1869 among men, forty occurred in smokers. In fifteen cases of hemiplegia, nine abused tobacco, and two used it moderately; four did not smoke. Of eighteen cases of paraplegia, five were great smokers, three moderate smokers, and ten abstained from tobacco. Out of twenty cases of locomotor ataxia, fourteen were great smokers, five moderate, and one abstainer.

Cincho-Quinine Pills.— The numerous requests from physicians in various parts of the country that cincho-quinine should be supplied in pill form, have led to their manufacture, and pills of 1, 2, and 3 grains each, elegantly sugar coated, can now be supplied in any quantity by the trade. They are packed in vials holding one hundred each, and the price is a little more than one half that of quinine pills, of corresponding sizes. The dose is the same.

Familiar Science.

[Communicated to Boston Journal of Chemistry.]

ENCKE'S COMET.

BY PROF. C. A. YOUNG, OF DARTMOUTH COLLEGE.

THIS comet, now in its most favorable position 'or observation, and faintly visible even by the ıaked eye in the early evening, derives its name from the distinguished astronomer who first, in .819, determined its orbit, and afterwards through ıis whole life expended great labor upon the ınvestigation of its motions.

In itself a very insignificant object, it derives ts interest mainly from the fact that its average listance from the sun, and of course its period ılso, is less than that of any other comet. It completes its course in a little less than three years and four months; at aphelion receding to ı distance of nearly 380 millions of miles from he sun, a distance as great as that of the remoter asteroids, while at perihelion it approaches within 31 millions of miles, or nearer than the planet Mercury.

Another circumstance has added to its celebrity. Since its first discovery there has been noticed a gradual shortening of its periods, which, according to the calculations of Encke, cannot be accounted for by any known action of the planets. He inferred, therefore, and maintained with great ability, the existence of a *resisting medium* filling the interplanetary spaces.

This conclusion, however, is by no means acquiesced in by all astronomers, because the other comets as yet show nothing similar, and it is thought quite possible that a new computation from the more accurate modern observations of the last five or six returns might show the presumed acceleration to be due to the disturbance of the planets, or even to a collision with some flock of such meteors as cause our November star showers. The question cannot be settled without a re-investigation of the whole matter. This would be exceedingly laborious, and thus far no one seems to have inherited Encke's paternal interest in the "little stranger."

As seen in the telescope at present, it is a rounded mass of nebulous matter some 5′ in diameter, with no definite outline and without a distinct nucleus, although it is considerably brighter in the centre. Last evening (Dec. 5) I detected for the first time a tail about half a degree in length.

The diameter of the comet is between 40,000 and 50,000 miles, and yet so transparent is it that when on Dec. 1st at 6.04 P. M. (Hanover time) it passed centrally over a little star of the 9th magnitude it did not in the least dim the star's brightness. For a minute or two, even with a power of 200, it looked as if it had simply acquired a nucleus. Similar observations have been often made before, and show that the substance of comets is inconceivably rare.

But the spectroscope speaks still more distinctly. It indicates that the material is gaseous, and so far as my observation goes, gaseous only; for there is no trace of any continuous spectrum such as must result from the presence of solid or liquid dust, in a state of however fine division. The annexed diagram represents this spectrum,

as observed here on Dec. 1st, 2d, and 5th. It consists of three bright bands, the central of which is far the brightest. The wave lengths of the less refrangible edges of these bands are respectively 557.5, 517.5, and 470.4 millionths of a millimetre. The spectrum seems to correspond exactly with that of Comet II., 1868, which was investigated by Huggins and by him identified as due to *carbon*.

SALT, NOT ATTIC.

NOTWITHSTANDING salt is an article of daily use in every household, there are comparatively few who know how or where it is obtained, or who are acquainted with the chemistry of this most interesting and important substance. It seems paradoxical that it should contain two violent corrosive poisons, and yet in itself remain so harmless. But these substances are only poisonous when separate; in combination, they are not only innocuous, but really essential to the well being of all animals.

If we take pure hydrochloric acid, and add to it common washing soda, until it is in slight excess, and then evaporate the mixture to dryness, we shall obtain a beautiful snow-white crystalline mass of pure salt, fit for table use. From this experiment we infer that salt contains some of the acid and also a portion of the soda.

Let us ascertain what portion of each of these substances it holds. Hydrochloric acid contains hydrogen and chlorine, and we may readily obtain the acid again from the salt by treating it with strong sulphuric acid in a glass flask. We should be led to infer from this that the acid existed already formed in the salt, and such was the opinion of chemists for many years, until Sir H. Davy proved the view to be erroneous. It is only the chlorine of the acid, that is found in the salt. The soda used is a compound of the metal sodium and carbonic acid, and when we add hydrochloric acid to this compound, we break it up, and form two new compounds, one of which is common salt, and the other carbonic acid. This latter escapes into the air, it being a gas at ordinary temperatures. It will be interesting to consider some of the properties of these two substances, chlorine and sodium. Chlorine is a yellowish green gas of a disagreeable odor, and extremely injurious when inhaled into the lungs. Even very small quantities irritate the throat and air passages, and produce all the symptoms of a violent cold. Sodium is a soft, white metal, which oxidizes rapidly in the air, forming caustic soda. It floats on water, which it rapidly decomposes, combining with its oxygen, and setting the hydrogen free. Taken internally even in minute quantities, it would act as a violent poison. It is these two harmful agents which go to form common salt when they are chemically combined, and thus the change results in the production of a body palatable and useful to the human organism. Men and animals, when entirely deprived of salt, become diseased, and ultimately die. Many years ago they punished criminals in Holland by depriving them of salt in their food, and it is stated they died a miserable death.

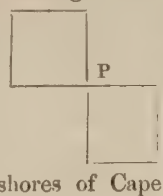
Salt is principally obtained from two sources: from the ocean, and from natural salt beds. Sea water contains on an average about 2.7 per cent. of the substance. Besides common salt, or sodic chloride, it contains several other substances, as is shown in the following analysis: —

Water	96.470
Sodic Chloride	2.700
Potassic Chloride	0.070
Magnesic Chloride	0.360
Magnesic Sulphate	0.230
Calcic Sulphate	0.140
Calcic Carbonate	0.003
Magnesic Bromide	0.002

Also there are found in sea water traces of iodine and silver. There are two methods of obtaining salt from sea water; one is by evaporation, and the other congelation. The latter method can only be used to advantage in very cold climates. It is a singular fact that when sea water is frozen, the ice formed is perfectly free from salt, water rejecting the saline ingredient in the act of crystallizing. The solution becomes more and more concentrated, and consequently it requires a greater degree of cold to form the ice.

In order to obtain salt by evaporation, the sea water is pumped by wind-mills into shallow wooden pans; or in countries where it can be done, it is allowed to flow over a salt marsh which has been previously prepared by removing all vegetation from its surface. The salt water is first received in a large shallow reservoir, where it is allowed to become moderately concentrated by the action of the sun's heat and the winds. From this it is conducted by a system of sluiceways into other reservoirs or evaporating basins more carefully constructed, and in these it deposits the lime salts. Finally, it is led into basins where it begins to deposit the salt; the water in these compartments being only a few inches in depth. Where the land is sufficiently below the level of the sea to allow the water to flow from one set of basins into the adjoining ones, of course the process is rendered quite easy; but if it is not low enough, the brine is raised at various stages by pumps moved by wind-mills. Salt produced in this way is called

bay salt, and can only be made in very dry countries, as a few hours' rain would spoil the labor of weeks. When wooden tanks are used they are generally protected from the rain by coverings. The tanks are made about ten feet square and a foot deep. The roofs are moved off and on by the aid of wheels running on rails; or, what is more common, two roofs are fastened together by their corners, and so arranged that they will turn about on a pivot, covering or uncovering two tanks by one movement, the tanks being arranged with regard to each other as shown in the diagram, the pivot being at P. The principal manufactories of salt from sea water, in this country, are along the shores of Cape Cod, and at Nantucket.



The deposits or beds of salt which are found in the earth, in various localities, are worked directly, and the salt is quarried in blocks, or detached from the mass in the same manner that coal is separated in mines. The most celebrated salt bed in the world is at Wielitzka, in Poland, where the substance has been mined for centuries. The salt from this mine is very pure, and may be used at once. The usual way of obtaining salt from the earth is by means of salt wells. These may either furnish a solution of salt ready for evaporation, or may only reach the salt bed without coming in contact with any water; in the latter case the water is supplied from the surface in the vicinity of the well. When water comes in contact with the bed it dissolves the salt, and the solution, being heavier than pure water, sinks to the bottom of the tube, from whence it is drawn by pumping.

Most of the salt wells in this country, however, are artesian borings, which furnish a constant flow of brine. The most extensive works of this kind are at Syracuse, N. Y. The salt water is received into tanks similar to those used upon the sea-shore, but the final concentration is accomplished in iron pans, heated by furnaces. The salt deposits in this country extend over the whole region between the Alleghanies and the Mississippi, but are in no case, if we except the bed at Petit Anse, Louisiana, of sufficient purity to admit of working directly upon the rock.

The bed at Petit Anse underlies 144 acres of ground, and has been penetrated to the depth of thirty-eight feet without showing any change in its purity. At some wells in the West the salt water is accompanied by large quantities of inflammable gas, which is utilized in evaporating the brine. The town of Fredonia, N. Y., is lighted with this gas, which has been flowing a number of years with no apparent diminution.

West of the Rocky Mountains salt is very abundant, often forming incrustations on the surface of the ground. The water of Salt Lake, in Utah, is almost a saturated solution, and the spray from its surface envelops everything with a crystalline covering.

Some time ago we analyzed a specimen of these saline crystals taken from a plain in California, with the following result: —

Sodic Chloride	94.39
Calcic Chloride	.86
Calcic Sulphate	4.05
Silica	.38
Water	.29
	99.97

Salt of this nature is pure enough for domestic use without undergoing any process of purification. These incrustations cover acres of ground on the Pacific coast, and look in the sun like vast fields of snow. Some of these salt plains are incrusted only at certain seasons of the year. When the rains come the salt is dissolved, and sinks into the earth, to reappear again during the dry season.

The use of salt is universal with all nations, civilized and savage, and when one barbarous tribe trades with another the first article of barter is generally salt. It is immensely valuable with those tribes who live remote from the natural sources of supply. Its use is also very ancient, for we find the same word used to designate salt in most of the languages of the world.

There is hardly a language that does not abound in proverbs relating to this substance. To eat salt with a man among the Arabs is a pledge of friendship. The Bible abounds with references to it, and one of these has no doubt puzzled many a reader. It is found in the Sermon on the Mount; "but if the salt have lost its savor, wherewith shall it be salted." This is explained by the fact that the salt used in Palestine is very impure, containing large quantities of magnesium, so that if kept in a damp place it becomes very bitter, and "is thenceforth good for nothing but to be cast out and to be trodden under foot of men."

Besides its use as an article of food, salt has numerous important applications in the arts. It is the source of all the chlorine that is so extensively employed in bleaching. In order to separate the chlorine from the sodium the salt is mixed with black oxide of manganese, and the mixture is then treated with dilute sulphuric acid.

Salt is one of the chemical agents provided for the use of man which is manifestly indispensable to his existence and happiness. It is furnished in the most bounteous manner, and the procurement and manufacture of the substance forms one of the great branches of industry of this and other countries.

THE SPHEROIDAL STATE OF LIQUIDS.

The remarkable phenomenon known as *the spheroidal state* was first observed in liquids, about a hundred years ago, by Leidenfrost, and has since been carefully investigated by scientific men. It is a subject of no little practical importance, as it furnishes the key to many otherwise inexplicable cases of boiler explosions.

If a few drops of water are allowed to fall upon a red-hot metallic surface (a silver or platinum cup is best for the experiment), the liquid gathers into a globule, which whirls about rapidly without boiling. It is also found that it does not evaporate nearly so fast as if it boiled, — only about one fifth as fast, according to the best authorities. When the metallic surface has cooled down to a certain point, it cannot keep the liquid in this spheroidal condition, as it is called, and a sudden and violent *boiling* ensues.

It is a singular fact that the temperature of the liquid while in this peculiar state is always below its boiling point. It is difficult to measure its temperature with precision, but in the case of water it is at least ten degrees (Fahrenheit) below its regular boiling point, and probably the difference is considerably more than that.

Another curious fact is that the liquid is not in contact with the hot surface. This has been proved in several different ways. The experiment may be so arranged that it is possible to *look* under the drop at a bright point or line beyond, and of course "seeing is believing." A fine wire connected with one pole of a galvanic battery may be made to dip into the liquid globule, and the other pole may be connected with the metallic surface or cup; so long as the spheroidal condition continues the galvanic circuit is not complete, but the moment that condition ceases the liquid touches the metal, and the galvanometer shows the passage of the electric current through the wires. There is a chemical demonstration of the same fact that is equally conclusive. A polished silver cup is used, and for the liquid a solution of sulphide of sodium. There is no action upon the silver while the liquid remains in the spheroidal state, but as soon as the cup has cooled enough for the drop to touch it, the instantaneous appearance of a dark spot upon the polished surface shows the formation of sulphide of silver. Nitric acid might be used as the liquid in this experiment, and it would not act on the silver so long as the latter was hot enough to keep up the spheroidal state.

How are these phenomena to be explained? As soon as the liquid comes near the heated surface, steam is produced beneath it, and acts as a spring to hold it up. In other words, it rests upon an elastic cushion of its own vapor, which is renewed by the heat below as fast as it escapes. When the cup cools down so that this vapor is not supplied with sufficient rapidity to buoy up the drop, the liquid falls upon the hot metal and boils.

The startling and paradoxical feat of freezing water in a red-hot vessel depends upon the property of liquids to remain below their boiling point while in the spheroidal state. A small quantity of liquid sulphurous acid is put into a red-hot platinum cup or crucible. It assumes the spheroidal state, and its temperature remains at about 12° F. or twenty degrees below the freezing point of water. If a little water is now added to it, the water instantly freezes, and the bit of ice may be thrown out of the red-hot vessel. This is but one of several ways in which the experiment may be performed.

The experiment of dipping the hand into melted lead is explained upon the same principle. The hand is instantly covered with a layer of spheroidal liquid, from its own moisture, and this prevents its coming in contact with the molten metal. The hand is exposed to radiant heat alone, which is mainly expended in forming the vapor that envelops it. The only danger is in not having the metal hot enough. Its temperature ought to be considerably above its melting point. If the hand is not naturally moist, it is well to wipe it with a damp cloth before immersing it in the metal. The experiment, if properly conducted, is a perfectly safe one, but few persons have the *nerve* requisite for trying it.

It is hardly necessary to explain how boiler explosions may be caused by the sudden change of water from the spheroidal state to that of violent ebullition. If the water is too low in the boiler, so that portions of the surface become red-hot, and water is then admitted, it may as-

ume the spheroidal condition, and as the over-eated metal cools down, its almost instantane-us conversion into steam may subject the boiler o a strain greater than it can bear.

A GREAT SUN SPOT.

PROFESSOR KIRKWOOD, of Bloomington, Ind., ommunicated to the *American Journal of cience and Arts* the following account of the reat sun spot of June, 1843: —

One of the largest and most remarkable spots ver seen on the sun's disc appeared in June, 1843, nd continued visible to the naked eye for 7 or 8 ays. The diameter of this spot was, according to chwabe, 74,000 miles; so that its area was many mes greater than that of the earth's surface. Now, has been observed during a number of sun-spot ycles that the larger spots are generally found at r near the epoch of the greatest numbers. The ear 1843 was, however, a *minimum* epoch of the even-year cycle. It would seem, therefore, that he formation of this extraordinary spot was an nomaly, and that its origin ought not to be looked r in the *general cause* of the spots of Schwabe's ycle.

As having a possible bearing on the question nder consideration, let us refer to a phenomenon bserved at the same moment, on the first of Sep-ember, 1859, by Mr. Carrington, at Redhill, and Ir. Hodgson, at Highgate. "Mr. Carrington had irected his telescope to the sun, and was engaged observing the spots, when suddenly two intensely minous bodies burst into view on its surface. hey moved side by side through a space of about irty-five thousand miles, first increasing in bright-ess, then fading away. In five minutes they had anished. . . . It is a remarkable circumstance, hat the observations at Kew show that on the very ay, and at the very hour and minute of this unex-ected and curious phenomenon, a moderate but arked magnetic disturbance took place; and a orm, or great disturbance of the magnetic ele-ent, occurred four hours after midnight, extending the southern hemisphere."

The opinion has been expressed by more than ne astronomer that this phenomenon was produced the fall of meteoric matter upon the sun's sur-ce. Now, the fact may be worthy of note that e comet of 1843, which had the least perihelion stance of any on record, actually grazed the solar mosphere about three months before the appear-ce of the great sun-spot of the same year. The met's least distance from the sun was about 65,000 iles. Had it approached but little nearer, the re-stance of the atmosphere would probably have ought its entire mass to the solar surface. Even its actual distance it must have produced con-lerable atmospheric disturbance. But the recent scovery that a number of comets are associated th meteoric matter, travelling in nearly the same bits, suggests the inquiry whether an enormous eteorite following in the comet's train, and having somewhat less perihelion distance, may not have en precipitated upon the sun, thus producing the eat disturbance observed so shortly after the met's perihelion passage.

BRIEF NOTES ON SCIENTIFIC TOPICS.

AN INTERESTING ELECTRICAL EXPERIMENT. — correspondent of the New York *Evening Post* ites as follows: "I connected the wire of a gal-nometer with the water-pipes of Baltimore, and e other end of the coil was joined to a gas-pipe a house in the southwest part of the city. Thus vast metallic system of electric nerves stretched ay three miles to the northwest, to the reservoir, d about as many to the east and southeast, over the city. A thunder storm was raging at the time, at so great a distance in the north that only the illumination of the clouds told when a flash oc-curred. Yet, whenever that flash took place, the needle was instantly deflected through ten or twenty degrees. The two occurrences were simultaneous, apparently, for I could detect no difference in the instant of their manifestation. Indeed, so sure an indicator of the flash was the galvanometer that when I shut myself up in a dark room, signalling to an observer of the storm whenever the needle moved, and receiving a signal from him when a flash occurred, our signals were always simultaneous. The next day it was ascertained that the storm was over twelve miles distant; therefore, at least five hundred square miles of the earth's surface were affected (inductively) at each flash of the light-ning."

ABSORBENT POWERS OF CHARCOAL. — Dr. H. Vohl, of Cologne, has been making elaborate ex-periments upon the absorbent powers of charcoal, and its use for disinfecting and deodorizing purposes. He thinks he has proved that the carbonic acid gas obtained by heating charcoal is not derived from the coal itself, but has been absorbed from the atmos-phere, and is held with such tenacity that it can-not be driven out by boiling in water, but that a temperature much below that of ignition is sufficient to expel it. This conclusion is the same as that which had been reached by another experimenter, to which we have previously made reference. Among other facts proving this statement, Dr. Vohl remarks that when charcoal has been once freed from its carbonic acid and saturated with pure oxygen, no trace of carbonic acid is appreciable, even when heated to a temperature of 680° Fahren-heit.

EFFECT OF COLD ON IRON AND STEEL. — For many years it has been almost an axiom among civil engineers, that great cold tended to produce a brittle condition of iron and steel, and that this hypothesis explained the alleged increase in the breakage of trees, axles, and rails in railroad traffic. According to the recent experiments of Joule and others, however, it would seem that iron and steel, instead of being weakened by freezing weather, are actually capable of resisting greater shocks than at a summer temperature. Dr. Joule refers the greater frequency of railway accidents in winter to the increased hardness of the *ground* caused by freezing, by which the iron is subjected to a greater strain or shock than in summer.

SIMPLE METHOD OF EXHIBITING ABSORPTION SPECTRA. — E. Lommel, in *Poggendorff's Annalen*, describes a method of exhibiting the absorption spectra of soluble coloring matters, whereby the employment of solutions in glass vessels is avoided. It consists in the use of gelatine plates colored by the required material, which, in order to avoid in-jury, are enclosed between glass plates. A collec-tion of various coloring matters can thus be made, which are at hand at any moment when required for demonstration. The preparation of perfectly homogeneous and transparent plates succeeds even with substances insoluble in water, but soluble in alcohol, such as aniline colors, chlorophyll, etc. Chlorophyll-gelatine, however, does not give the same absorption spectrum as a chlorophyll solution, but that of solid chlorophyll, as exhibited by leaves in transparent light. Such a difference in the spectra was not observed with any other coloring matters.

INFLUENCE OF GREEN LIGHT ON THE SENSI-TIVE PLANT. — In order to test the effect of green light on the sensitiveness of the *Mimosa*, M. Bert placed several plants under bell-glasses of different colored glass, set in a warm greenhouse. At the end of a few hours a difference was already appar-ent: those subjected to green, yellow, or red light had the petioles erect, and the leaflets expanded; the blue and the violet, on the other hand, had the petioles almost horizontal, and the leaflets hanging down. In a week those placed beneath blackened glass were already less sensitive; in twelve days they were dead or dying. From that time the green ones were entirely insensitive, and in four days more were dead. At this time the plants un-der the other glasses were perfectly healthy and sensitive; but there was a great inequality of de-velopment among them. The white had made great progress, the red less, the yellow a little less still; the violet and the blue did not appear to have grown at all. After sixteen days the vigorous plants from the uncolored bell-glass were moved to the green; in eight days they had become less sen-sitive, in two more the sensitiveness had almost en-tirely disappeared, and in another week they were all dead. Green rays of light appear to have no greater influence on vegetation than complete ab-sence of light, and M. Bert believes that the sensi-tive plant exhibits only the same phenomena as all plants which are colored green, but to an excessive degree.

CHANGE IN THE HABITS OF A BIRD. — A writer in *Nature* records a remarkable instance of the en-tire change of habits in one of the native birds of New Zealand since the colonization of the island by Europeans. The Kea (*Nestor notabilis*) is a mem-ber of the family of Trichoglossinæ, or brush-tongued parrots, feeding naturally on the nectar of various indigenous flowers, or occasionally on insects found in the crevices of rocks or beneath the bark of trees. For several years past the sheep in the Otago dis-trict have been afflicted with what was thought to be a new kind of disease, first manifesting itself in a patch of raw flesh on the loin, the wool gradually coming completely off the side, and death being often the result. It was discovered that this was caused by the attacks of the Kea, or mountain-par-rot, which threatens to become exceedingly destruc-tive to the flocks. It is supposed that the taste for this kind of food was first developed from the par-rots being induced in the winter season, when their proper food was scarce, to attack the "meat-gal-lows" on which the carcases of sheep were hung to dry the skins.

HOUSEHOLD RECIPES.

A GOOD WHITEWASH. — Mix up half a pailful of lime and water. Then make a starch of half a pint of wheat flour, and pour it into the whitewash while hot. Stir it well, and it is ready for use. This is one of the simplest and best recipes, and the whitewash made by it will not rub off.

TO CLEAN TIN COVERS. — Mix a little of the finest powdered whiting with the least drop of sweet oil, rub the covers well with it, and wipe them clean; then dust over them some dry whiting in a muslin bag, and rub bright with dry leather. This last is to prevent rust, which the cook must guard against by wiping them dry and putting them by the fire when they come from the dining-room, for if but once hung up damp the inside will rust.

SPOTS ON MAHOGANY. — Stains and spots may be taken out of mahogany with a little aquafortis and water, or oxalic acid and water, rubbing the part by means of cork, till the color is restored, observing afterwards to wash the wood well with water, and to dry and polish as usual.

A GOOD TABLE SAUCE. — Take one gallon of tomatoes, wash and simmer in three quarts of water until nearly done. Strain through a sieve. Add two tablespoonfuls of each of these spices: ginger, mace, black pepper, allspice, and salt, and one of cayenne pepper. Boil down to one quart. Pour in one half pint best vinegar, and then pass the whole through a hair sieve. Bottle in half-pint bottles; cork and seal securely, and keep in a cool place.

The Arts.

EARTH BORINGS FOR ILLUMINATING GAS.

THE subject of oil wells has been so often discussed, and the methods for procuring earth oil have been so fully described, that every intelligent reader is familiar with the whole matter. It may not be generally known that the earth is not only a vast oil reservoir, but a huge gas holder, and that borings have been made into the gas caverns below, through which immense quantities of the best illuminating gas have flowed to the surface. Professor J. S. Newberry, of Cleveland, writes as follows to the *American Chemist* regarding some gas wells in Ohio: —

In June, 1866, I visited two remarkable gas wells bored by Mr. Peter Neff, in the valley of the Kokosing, a few miles east of Gambier (where Kenyon College is located), in Knox County, Ohio; I wrote a description of them which was published in the *Cleveland Herald*. As gas wells are just now attracting some attention as sources of supply of gas for illumination and fuel, I have thought it might not be uninteresting to your readers to have this description repeated for their benefit.

It will probably add to the interest with which it will be read, to say that the wells described below *have been flowing gas in apparently undiminished volume to the present time.*

From Gambier our route lay down the valley of Kokosing, some twenty miles to the junction of that stream with the Walholding. Within this interval the valley has nearly an east and west course, and is excavated in the "Waverley" (lower carboniferous) formation, in the direction of the dip of the strata, which is here eastwardly about twenty-two feet to the mile. Near Millwood, however, a few miles below Gambier, we crossed a belt of a mile or more in width, in which the rocks are much disturbed, the dip being increased to 30° with the horizon. Such disturbances are hopeful signs in an oil region, as they indicate the existence of subterranean fissures and cavities in which the oil may accumulate, and without which no great oil wells are possible. Two wells have been bored near this break, one above, the other below. These are flowing, one three, the other eight gallons of oil per day, and are soon to be thoroughly tested by the pump. Two or three miles below, and near the mouth of the Kokosing, two other wells have been bored to the depth of 600 feet, penetrating argillaceous shale, with bands of sandstone. On reaching the third sand rock at the depth of 600 feet, the auger, in both wells, struck upon nearly vertical crevices, into which it penetrated several feet without resistance. From these crevices issued a volume of carburetted hydrogen gas without parallel, so far as I am informed, in all the oil explorations made in the country.

In both wells copious streams of salt water had been previously met with, and the wells were filled when the gas chambers were struck, but this water was ejected with such violence as to form intermittent fountains over one hundred feet in height. The first of these two wells was bored during the winter, and the water thrown out soon covered the derrick with ice, forming a kind of chimney sixty feet in height. Through this the water was thrown at intervals of about one minute, to double that height, or 120 feet. After, and with the water, came a great rush of gas, which continued until the pressure was relieved, when the water again began to accumulate and was again ejected. This series of phenomena has been repeated with unvarying regularity and undiminished force, for some months.

At the time of my visit an effort was being made to tube the well, by which the flow of water and gas was somewhat impeded, and I did not witness the full effect of the paroxysm, but a series of photographs which I saw, fully confirmed the description given me by Prof. H. S. Smith and others.

When the derrick was covered with ice, the gas escaping from the well was frequently ignited, and the effect, especially at night, of this fountain of mingled fire and water, shooting up to the height of 120 feet through a great transparent and illuminated chimney is said to have been indescribably magnificent.

In well No. 2, which has a history similar to that of No. 1, the gas chamber was opened on the 1st of March, but this well has been carefully cased and the water all shut off, so that the gas is permitted to escape without impediment. A pipe two inches in the clear is set in the well-head, and from this a constant stream of illuminating gas is now, and for three months has been, escaping with a sound audible some distance from the well.

At the time of our visit nearly 100 feet of pipe was connected with the well, and thus, at a safe distance, the gas issuing from it was ignited. The effect, even in bright sunshine, was surprising. A jet of flame was formed 20 feet or more in length and as large as a hogshead. By fixing a stop-cock on the pipe the gas was made to accumulate until, measured by a steam-gauge, the pressure amounted to 180 pounds to the square inch.

This was as great a pressure as the gauge would indicate, but it is evident that the pressure below is much greater than that, as the weight of the column of water, 600 feet high, lifted by it is 262 pounds to the square inch. When liberated after confinement of a few minutes, and ignited, the gas formed a volume of flame as large as a house. At night an exhibition similar to that witnessed by us at mid-day is said to be wonderfully impressive, the gas illuminating the whole country like a conflagration.

The gas from these wells seems to be pure, having no other smell than an agreeable one of naphtha, and has high illuminating qualities. Its volume is sufficient to light a large city, and, if differently situated, the value of the material thus wasted, for lighting or heating, would be greater than the product of the best oil-well known.

NEW THINGS IN THE ARTS.

SHEET IRON COATED WITH COPPER OR BRASS. — The coating of sheet iron plates with copper and brass is a new industry that promises well. Among the advantages claimed for such plates over those which are tinned or "galvanized," is the fact that they can be annealed to any desired extent during the process of stamping, without injury to the copper or brass coating; and that they also are superior to sheet copper or sheet brass, because articles manufactured from them are not so readily bent or dented as when they are made of brass or copper, and they can be burnished, planished, or spun, and so brought to any required degree of finish. On this account, the material is specially adapted to the manufacture of lamps, candlesticks, and all kinds of goods hitherto made by stamping from sheet brass or sheet copper, and at a greatly reduced cost.

A NEW AND CHEAP METHOD OF PREPARING PURE DEXTRINE. — For this purpose, 500 parts of potato-starch are mixed with 1,500 parts of cold distilled water and 8 parts of pure oxalic acid, and this mixture placed in a suitable vessel on a water-bath, and heated until a small sample tested with iodine solution does not produce the reaction of starch. When this is found to be the case, the vessel is immediately removed from the water-bath, and the liquid neutralized with pure carbonate of lime. After having been left standing for a couple of days, the liquor is filtered, and the clear filtrate evaporated upon a water-bath until the mass has become quite a paste, which is removed by a spatula, and, having been made into a thin cake, is placed upon paper and further dried in a warm place. 220 parts of pure dextrine are thus obtained.

ECONOMICAL STEAM ENGINES. — An engine builder in London is now constructing steam engines that are guaranteed to consume less than two pounds of coal per horse power, each hour; and it is claimed that in some cases these engines have consumed only one pound per horse power, each hour. This is nearly one fifth of the theoretical amount of power that is produced by the consumption of coal. One tenth has been considered very good work heretofore.

CONCENTRATED VEGETABLES. — A new process for preserving the solid parts of vegetables without impairing their flavor has been patented. The treatment pursued in the case of potatoes will serve as an illustration of the method. After being thoroughly washed they are boiled until done, and their skins removed. The potato is then divided into fine vermicular particles by mechanical means, and while in this state the water is driven off by exposure to heat. The material is left in a condition much resembling rice, and in this shape it may be ground to flour if desired. The extract of potatoes prepared in this way can be used for making soup and other dishes; and by adding boiling water, a dish in every way resembling mashed potatoes cooked directly from potatoes in the ordinary manner, is obtained, but, it is said, of superior flavor and quality.

AN ICEBERG ALARM. — A New Yorker has invented an apparatus to be attached to ships, so arranged as to sound an alarm on approaching the vicinity of an iceberg. The device is arranged on the bottom of the vessel, and is of such a nature that when the keel strikes any very cold stratum of water the alarm is sounded. It is well known that icebergs refrigerate the water around them for a considerable distance. This instrument will exhibit the exact temperature of the water below the vessel at all times.

MOTHS. — In India, both upholsterers and saddlers were badly troubled with moths in their work especially in the rainy season; and the upholsterers in that country follow a series of simple rules by which they entirely avoid the ravages of these pests. They never put on a burlap or cotton covering without first steeping it in a solution of sulphate of copper, made by dissolving about one ounce in one gallon of boiling water, and then quickly drying the material in the sun or by a hot stove. For over coverings, especially if of wool, a solution of corrosive sublimate dissolved in patent colorless alcohol is frequently used with good effect. The boiling solution of sulphate of copper is often applied to a floor previous to laying a mat or carpet, and invariably under heavy articles of furniture.

ENGRAVING BY ELECTRICITY. — An ingenious French mechanic has produced an invention by which a metal plate, upon which a design is drawn with a chemical ink of some kind, is slowly rotated with its face vertical; and several other similar plates, graded in size, are also slowly rotated by appropriate mechanism. The object of the invention is to engrave on the smaller plates the design traced upon the largest, on different scales of magnitude, which is accomplished by applying a cutting point to the face of each plate, which is pressed against it by means of an electric current whenever a blunt point, applied to the large plate encounters the ink in which the design is traced — the cutting points being at other times withdrawn. The point presented to the first plate is merely a "feeler," which determines by electrical agency

hether the ink is beneath it or not. If it is, the oints are pressed into the surface of the other lates; if not, they are withdrawn and prevented rom cutting. The feeler and the burins must, of ourse, all follow a spiral track. This is crude, and an be made applicable to the reproduction of certain kinds of designs only, but it is considered a ong step in the direction of practical success.

A NEW MANUFACTURING ENTERPRISE IN RANCE. — An important work of hydraulic engineering has been recently commenced with the view f utilizing the fall of the Rhone at Bellegarde, near eneva. By driving a tunnel about 600 yards ong, about a third of the water will be diverted om the river, and delivered into the neighboring alley of the Valseriane, with an available fall of 44 et, the supply being estimated at rather more an 2,000 cubic feet per second at the period of owest water. This corresponds to 10,000 horse ower, or as much as that which has made Lowell e Manchester of America. The promoters of the nterprise point out that the position is admirably tuated for the erection of cotton and woolen mills, s, in addition to furnishing power, the water is of xceptional purity.

A NEW USE FOR DYNAMITE. — This explosive as been most usefully employed in France in rending the roots of timber trees. In the Forest of Haye, Meurthe-Moselle, where an immense quantity f timber was blown down by storms, the roots emained, encumbering the ground. A hole being rilled from 9 to 15 inches deep, a dynamite cartridge f 50 grammes — about 800 English grains — provided with a fulminating cap and safety fuse, was laced in it. When the charge was exploded the tump was rent into pieces, which were easily removed.

PRACTICAL RECIPES.

GLYCERINE COMPOSITION FOR LEATHER. — As s well known, glycerine has found extensive application in tanning, as it has been discovered that it dds materially to the elasticity and strength of the eather. Especially has it been found of great alue in protecting leather bands of machinery from racking and drying. The partially tanned leather s immersed for a considerable time in a bath of lycerine, by which the pores are filled, and such an lasticity and softness is imparted that objects manufactured from it are much less liable to break.

In order to prepare a neutral gutta percha composition with glycerine, take 3 to 4 pounds lampblack and ½ pound ivory black; cover up in a uitable vessel, with 5 pounds glycerine and 5 ounds common syrup, and stir well until the whole s intimately mixed and free from lumps. Four or ve ounces of gutta percha, finely cut, are to be put nto a kettle, and, after melting, must be mixed ith 20 ounces of sweet oil and dissolved, and two unces of stearine added. While still warm, the utta percha solution must be incorporated with the yrup and lampblack, and after this is done, 10 unces of Senegal gum, dissolved in 1½ pounds of ater, is also added. In order to impart an agreeable odor to the mass, a small quantity of rosemary r lavender oil may be introduced.

In using, the glycerine gutta percha paste must e diluted with three or four parts of water. It ives a fine lustre, and, as it contains no acid, it oes not injure the leather, but makes it soft and lastic, and adds very much to its durability.

IMITATION AMBER. — 1. Boil turpentine with a ittle cotton — some add oil — stirring till thick as aste; set it in the sun for eight days, and it will e clear and hard. 2. Take yolks of 16 eggs, and eat them up well; take gum arabic 12 oz., cherry ree gum 1 oz.; powder, and mix with the yolks. Let the gums melt well, and put them in a pot well eaded; then set for six days in the sun. 3. Whites of eggs; beat them well, mix with strong white wine vinegar, stop close, and let stand fourteen days. *The Cabinet Maker* endorses these recipes.

CARBOLIC ACID IN PASTE, ETC. — To prevent the decomposition of paste, add to it a small quantity of carbolic acid. It will not then become offensive, as it often does when kept for several days, or when successive layers of paper are put on with the paste. In the same way, the disagreeable smell which glue often has may be prevented. If a few drops of the solution be added to ink or mucilage, they will not mould. For whitewash, especially when used in cellars and dairies, the addition of an ounce of carbolic acid to each gallon will prevent mould and the disagreeable odor which sometimes taints milk and meat kept in such places. It also drives away cockroaches and other insects.

RED FIRES WITHOUT SULPHUR. — The following gives a light which is nearly orange in color : —

Nitrate of strontia	4 parts.
Rosin	1 part.
Chlorate of potassa	1 "

The following produces a large, powerful, somewhat orange-colored flame : —

Nitrate of strontia	24 parts.
Chlorate of potassa	16 "
Lycopodium	3 "
Sugar of milk	2 "

A rose-colored flame may be obtained by the following : —

Chlorate of potassa	12 parts.
Nitrate of potassa	5 "
Sugar of milk	4 "
Lycopodium	1 part.
Oxalate of strontia	1 "

The ingredients must be perfectly dry, and must be carefully and thoroughly mixed. They may be burned in open pans, or packed in paper moulds.

Agriculture.

OXALIC ACID AND PLANTS.

THE frequent reference in agricultural and other journals to oxalic acid as a constituent of plants has awakened considerable inquiry regarding the history and nature of the substance. The eminent Swedish chemist, Scheele, first discovered the acid, having found it in the juice of the common sorrel, where it exists as a binoxalate of potash. It is generally known under the name of "salt of sorrel," and is very sour to the taste, and poisonous when taken internally. The crystals, in form and color, so closely resemble those of the sulphate of magnesia (Epsom Salts) that they have often been mistaken for them, and fatal cases of poisoning have resulted from the error. The name, oxalic acid, is derived from the Latin name of the common wood sorrel, *Oxalis acetosella.* The field sorrel, so plenty and so troublesome to farmers, belongs to an entirely different family of plants, the *Rumex acetosella*, and is classified among the docks. This contains considerable of the acid, as also do the lichens, in which it exists as oxalate of lime.

Oxalic acid is the most highly oxidized of all carbon compounds, with the one exception of carbonic acid. It belongs low down in the list of organized products, and may well be regarded as constituting the last stage in the oxidation of carbonaceous substances before they pass into the dead, inorganic condition of carbonic acid. In plants, it seems to be more the product of *decay* than of growth. In lichens, especially, this would appear to be true, as the oxalate of lime found in them forms nearly thirty-five per cent. of the weight of the plant, and it exists in them in its most insoluble form. In garden rhubarb, the acid is found locked up with lime, and it is a significant fact that it is more abundant in old, than in the new plants. We incline, so far as its connection with plants is concerned, to class it with lignin and some other bodies, — a material which the plant has no further use for, and therefore deposits in the cells in an insoluble condition. All the vegetable acids are inactive agents in plant organisms. They do not appear to perform any leading part in vegetation, and in all their physical and chemical relations are widely different from the active soluble salts, and other bodies which are found dissolved in the sap.

Oxalic acid can be produced artificially with great facility, and it is manufactured and employed in the arts in large amounts. It is curious that in *sawdust*, an utterly waste product, we have a material from which this acid can be produced to any extent, and nearly all of the substance found in the market is now made from sawdust. The sawdust is placed in large vats and moistened with a lye made of caustic soda and potassa. It is then taken out and dried on plates of iron, and the dry mass is washed with warm water to dissolve out everything except the sparingly soluble oxalate of soda. The mother liquors are evaporated to dryness and ignited, to save the potassa, which is used over again. The oxalate of soda is decomposed by boiling with caustic lime; the soda enters into solution and may also be used over again. The oxalate of lime in turn is decomposed by sulphuric acid, and the liquor decanted from the insoluble sulphate of lime, which, upon concentration, yields crystals of oxalic acid. This is a brief, imperfect description of an interesting chemical process, and serves to illustrate how science triumphs over obstacles, and produces substances peculiar to vegetables from waste materials. The cost of production is very small, not exceeding a few cents a pound, and if the acid would act upon feldspar, and liberate the potash it contains, as some suppose, its employment might supply a cheap method of procuring this most valuable plant food. But this idea is erroneous, as we have endeavored to show in some former statements.

If the acid is at any time swallowed by mistake, an antidote to the poison is found in any substance containing carbonate of lime, or caustic lime; as such, when brought into its presence, convert it into insoluble oxalate of lime, a substance which is harmless. Chalk, whiting, or plaster from the walls of a room, will serve a good purpose, and either one of these in quantity equal to the amount of acid taken, should be stirred in water and drank as speedily as possible.

NORTHERN CORN ON SOUTHERN SOILS.

SEVERAL of our friends and patrons in the Southern States sent to us last spring for seed corn, with the design of testing its adaptability to that climate and soil. We regret to learn that the experiments made have not proved satisfactory, the results showing that our Northern varieties of the maize plant cannot be raised successfully in that section. J. R. Maxwell, Esq., an intelligent and enterprising farmer at Tuscaloosa, Alabama, procured *twelve bushels* of our Lakeside corn, and planted 48 acres of land; and he writes that his crop was an entire failure,

having gathered only 25 bushels of *nubbins.* He remarks, that he could have raised of the white corn at least 750 bushels, so that the experiment has cost him about $600. The failure he attributes solely to want of adaptability of climate. "Experience," he says, "teaches some important lessons, and as regards the corn experiment, we have learned what neither you nor I knew before. We could see no good reason why the yellow corn would not grow here, but now we know it will not." If we had understood that so extensive a trial was contemplated, we should have advised a smaller one, as it is always best not to risk much where the way is unknown or uncertain. Mr. M. is now trying some other experiments of considerable magnitude, which we most sincerely hope will turn out better. He sowed in September a cotton-field of 180 acres, one half with barley and the other with rye, and in October he sowed 20 acres with red clover. His design is to save a few acres of the grains for seed, and turn under the balance in February and March, and plant to cotton. He will give to the land at the time of turning under, 25 bushels of crushed cotton seed, and about 150 lbs. of superphosphate to the acre. But few men at the South are more enthusiastic in soil cultivation than Mr. Maxwell, and his success has been commensurate with his enterprise. The influence of such gentlemen upon the agricultural interests of the country is very great, and the example he is placing before other cultivators in the South is of the most important and salutary nature.

PLANT GRAPE-VINES.

It is surprising that so many families in the country are willing to live year after year without cultivating a single grape-vine about their dwellings. They are compelled to purchase the delicious fruit for the table, or not taste it during the season. There is a common impression that to cultivate grapes properly a vast amount of knowledge and tact is required. To many, the simple trimming of a vine is a mystery, more difficult to comprehend than the hardest problem of Euclid. This is an erroneous view, and ought not to prevail. Any person of common intelligence can learn in one hour how to trim and nourish vines, and if instruction cannot be obtained from some experienced cultivator, there are books filled with cuts and illustrations which make everything plain. Three vines, of as many different varieties, planted in some sunny nook, or by the side of buildings, so as to obtain shelter, will, if properly cared for, furnish many bushels of delicious grapes every year. Select a Concord, a Delaware, and an Adirondack, make the ground mellow and rich by the use of the spade, and by employing old manure, fine ground bone, and ashes, and set out the plants. In three years the rich clusters will appear, and in four years the product will be abundant. It is well to have vines planted so that the waste liquids from the dwelling can be used in fertilization. If there is any food the vine specially loves, it is the soapy liquids which accumulate on washing days in families. Vines drenched every week with these liquids will flourish astonishingly, and extend themselves so as to cover large buildings, every branch bearing fruit. We say to our readers everywhere, plant vines.

AGRICULTURAL COLLEGES.

A meeting of officers and others connected with the agricultural colleges of the several States was held at Chicago last summer, for the purpose of consultation regarding the proper management of these institutions. Professor Flagg offered the following resolution at the meeting, which was voted down, and very properly we think: —

Resolved, That the object of the organization to be formed by this meeting should be the advancement of the interests of industrial education by assembling together persons engaged in agricultural and mechanical experiment and education, and with the view of increasing and disseminating industrial knowledge.

Professor Detmers said "that it made no difference whether knowledge was obtained from Nature or schools. It was a fact that those who obtained their knowledge from schools did not often succeed." The committee on experiments then offered the following resolutions which were adopted: —

The field of experiment in its widest sense, in relation to our colleges founded on the national grant, is large, and crowded with work. We want

I. Meteorological observations.
  1. Scientific, after Smithsonian plan.
  2. Practical, like those of the Signal Service.

II. Mechanical experiments.
  1. In strength of materials.
  2. In motive powers.
  3. In trials of agricultural and other industrial implements.

III. Experiments in physics, especially in the effects of different degrees of light, heat, electricity, and moisture, on vegetable life.

IV. Experiments in industrial chemistry, such as analyses of soils, of clays, and other earths used in the arts; of coals, lime and building rock, minerals, manures, plants, and their products, and of animal products.

V. Experiments and observations in mining and metallurgy.

VI. Experiments with soils in their drainage; pulverization by different implements, and their compaction; the application of different fertilizers; the variation of soils in adjoining plats, their continuous cropping without manure, and their irrigation.

VII. Experiments in special culture with different varieties of grasses, grains, roots, plants, etc., with variations in the time, distance, and depth of planting; modes of cultivation; harvesting; manuring; modes of propagation; and with diseases and insects affecting plants.

VIII. Experiments in the breeding and fattening of domestic animals, comparing different breeds and species, their diseases, etc.

It is undoubtedly very well that the agricultural colleges, so called, should have some plan, or should adopt some system of instruction, which may comprehend a unity of purpose, such as will enable the different institutions to compare results, and thereby obtain important facts applicable to the differing interests of the country.

But the resolutions adopted do not manifestly cover the right ground, or rather they do not point out the true work of agricultural colleges. As regards meteorological observations, we think the work is being done by the Signal Corps far better than it can be done by students or any association of private irresponsible persons; and besides, what is the need of such observations?

It is well enough to have students taught the elements of meteorology, but any further instruction or experimenting is a waste of valuable time, which might be devoted to more useful studies.

The second class of experiments, as enumerated, embrace points, or kinds of experiment which are unnecessary, because they have been quite satisfactorily settled.

The strength of materials and motive power have been made the subject of study by mechanical engineers for years, and the tables published are full and complete. Government engineers have in their experiments exhausted this branch of research. Of what use is it to continue such experiments in agricultural colleges? None whatever.

The remainder of the list of experimental labors proposed is certainly quite comprehensive and embraces about every branch of study open to investigation.

If everything is to be studied and settled why not attempt to solve some of the more intricate problems relating to the origin of man or why not make exact determinations of the atomic weights? The country is much in need of good practical educated farmers, and we suppose it to be the business of agricultural colleges to produce such, and send them out that their influence may be felt everywhere. Our colleges and high schools teach the classics and the higher mathematics; why is it necessary to introduce these and kindred studies into schools of agriculture? These schools are designed for special work, and that work is of the most practical and important character, and it seems to us that it would be a positive misfortune to have them diverted, so that the distinction between them and ordinary educational institutions shall consist only in the name.

SEEDS AND CUTTINGS.

How to make a City Garden. — Take barrels and bore holes around the middle, and one hole large enough to admit the nose of your watering pot. Fill the barrels with stones as high as the rows of holes, and fill in with good, rich, fine earth to the top, in which plant cucumbers, melons, squashes, tomatoes, etc. One barrel will be enough of each kind.

Be sure to have one flat stone lean over the large hole, where you will pour in water until it runs out of the holes you have made, and which will prevent the earth from filling this large hole up. Range the barrels around your yard, and plant your seeds. Keep the barrels filled with water up to the holes, and you have all the requisites for rapid, healthy growth, — air, heat, and moisture. You can raise all the vegetables you will need, in the greatest perfection, and they will last until late in the autumn, as they can easily be covered on frosty nights. Cucumbers and tomatoes may hang over the barrels, cutting them off when they reach the bottom. Melons may be tied to the wall fence. The stones have an important service in holding up the earth, and absorbing the heat during the day, which they give out at night, keeping the water at an even temperature. You will be astonished at the result if you have never tried it. — *The Prairie Farmer.*

Arranging Flowers for Bouquets. — It is an art, requiring no small degree of taste and skill to arrange cut flowers so as to form an attractive bouquet for the vase or basket. It is something, too, which comes to one intuitively, and it can hardly be described in words. However, it may be said in general that the more loosely and uncon-

ısed flowers are arranged, the better. Crowding : especially to be avoided, and to accomplish this, good base of green of different varieties is needed ɔ keep the flowers apart. This filling up is a very nportant part in all bouquet making, and the neg- ect of it is the greatest stumbling-block to the ninitiated. Spiked and drooping flowers, with ranches and sprays of delicate green, are of abso- ıte necessity in giving grace and beauty to a vase ouquet. Flowers of similar size, form, and color ught never to be placed together. Small flowers hould never be massed together. Large flowers, 'ith green leaves or branches, may be used to ad- antage alone, but a judicious contrast of forms is ıost effective. Avoid anything like formality or tiffness. A bright tendril or spray of vine can be sed with good effect, if allowed to wander over nd around the vase as it will. Certain flowers as- ort well only in families, and are injured by mix- ıg. Of these are balsams, hollyhocks, sweet peas, tc. The former produce a very pretty effect if laced upon a shallow oval dish upon the centre ıble. No ornament is so appropriate for the din- 'er table or mantel as a vase of flowers; and if you xpect visitors, by all means cut the finest bouquet our garden will produce, and place it in the room ıey are to occupy. It will tell of your regard and ffectionate thoughtfulness in a more forcible and ppropriate manner than you could find words to xpress. If a small quantity of spirits of camphor ; placed in the water contained in the vase, the olor and freshness of the flowers will remain for a ıuch longer period. Thus prepared, we have had owers to keep a week, and at the end look quite 'esh and bright. — *The Maine Farmer.*

Soil for Fruit Trees. — It will generally be ound that fruit trees in clay soils will be far more arifty than in sandy or loamy lands. The reasons re plain. A clay soil has more moisture and re- ains it longer than the others, which are more po- ous. But if the clay soil is not well drained, and as not a good subsoil, it may prove very injurious om an excess of water. A good loamy surface oil, with clay subsoil, is always desirable, and bet- er than clay undrained.

Deep Planting of Fruit Trees a Preven- ive of Blight. — Out of eight to ten hundred 'pple trees so deeply set that an ordinary spade ırust square down will not reach the uppermost oots, we have yet to see the first case of bark-burst- ıg or blight. We attribute the exemption of our ees from these diseases, or whatever else they may e called, solely to deep planting, and nothing else. Ve do not know of another orchard about us where ıe trees are set so deep, nor do we know of one of der or equal age wherein cases of blight or bark- ursting have not occurred. — *Western Pomologist.*

The Castor-Oil Plant. — This plant is a ative of India, and has been known from the earli- st antiquity, seeds of it having been found in Egyp- an sarcophagi. It was used by the Greeks. In s native country it is a perennial fifteen or twenty et high, with a thick stem. In cold climates it ecomes an annual. There are many instances of erennial plants becoming annuals by change of imate.

The rapid growth of the plant is illustrated by an ıstance reported in Tennessee. A castor bean was lanted in May, 1871, in a garden in Memphis, and ı November it had grown to the height of twenty- ıree feet, with a spread of foliage fifteen feet in iameter. The trunk, ten inches above the ground, as eighteen inches in circumference.

Emerson says: "In the great household of ature, the farmer stands at the door of the bread oom, and weighs to each his loaf."

Boston Journal of Chemistry.

Jas. R. Nichols, M. D., *Editor.*
Wm. J. Rolfe, A. M., *Associate Editor.*

BOSTON, JANUARY 1, 1872.

PUBLISHERS' NOTICE.

All correspondence relating to the business of the Journal, remittances, etc., must be addressed, "Boston Journal of Chemistry, 150 Congress Street, Boston, Mass."

All correspondence relating to editorial affairs should be addressed to the Editor, 150 Congress Street, Boston.

Mr. A. D. Blanchard *is no longer a Travelling Agent for the Journal. All money paid on Journal account should be sent directly to the office,* 150 *Congress Street.*

TO ADVERTISERS.

The publishers desire to inform those who wish to advertise books, musical instruments, dental instruments, college announcements, schools, institutes, lectures, chemicals, and chemical apparatus, drugs, medicines, and druggists' wares, steam-engines, furniture, glass-ware, agricultural implements, fertilizers, soda-water apparatus, etc., etc., that this journal is one of the best mediums for advertisers in the United States. Its circulation is larger than any journal of its class published either in this country or in Europe. Every number is read by at least ONE HUNDRED THOUSAND *persons scattered in the various States, and in foreign countries, and the readers are among the most enterprising and intelligent classes. Nearly one half of our subscribers, are physicians, dentists, and druggists; the remainder are farmers, mechanics, students, professors in colleges, merchants, etc. Advertisers will find it for their interest to advertise their wares in the columns of the Journal.*

CHEMICAL ANALYSIS.

J. R. Nichols & Co., 150 *Congress Street, will make accurate chemical analysis of minerals, ores, drugs, dyes, chemical substances, commercial articles, and spring, river, or well waters, suspected to contain lead, zinc, or other deleterious metals, upon the most reasonable terms. Circulars of information sent upon application.*

PUBLISHERS' NOTICE.

Those of our subscribers who have not paid for the Journal for 1872, will find bills wrapped in the January number. Please remit as speedily as possible. No doubt, in sending so many bills, some will fall into the wrong papers, and pass into the hands of those who are not in arrears. If this happens, our friends will understand the matter, and they can throw the slip into the fire.

The Time to Subscribe. — During the month of January we usually receive large accessions to our family of readers. We confidently expect that our list will be increased by several thousand during the month; it certainly will be if our friends aid us in calling the attention of those to it who do not understand its character. The name, Journal of *Chemistry*, repels many, as it is presumed that it treats of subjects which common readers cannot understand. This is a mistake, as all our patrons know; and it only needs brief explanations on their part, to induce friends and acquaintances to become its readers and strong supporters. Please speak a word for the Journal.

One Subscriber. — But few of those who read the Journal are so situated that they cannot obtain one new subscriber if they will take the trouble to try. As an inducement, we offer to send a duplicate copy during the year, to any one who will send us a *new name and one dollar.* This offer will hold good during the month of January. The duplicate copy we will send to any name which may be given us. It will be understood that this offer gives *one dollar* to any person who secures *two* names with full pay, or it affords opportunity to send the Journal gratuitously to any friend or relative in any part of the United States. For *ten* new names, and ten dollars, we will send the fine *Household Microscope*, which has been advertised in the Journal; and for *five* names we will send Dr. Nichols' new book, "Fireside Science," just published by Hurd & Houghton, New York.

ENGLISH OBSERVATIONS OF ENCKE'S COMET.

Since the interesting article by Professor Young which appears on our first page was in type, we have seen the reports of the meeting of the Royal Astronomical Society, of England, on the 17th of November. Dr. Huggins there stated that he had succeeded in obtaining the spectrum of the comet, which, as in the case of that of Comet II. of 1868, consisted of three bands, apparently identical with the bands in the spectrum of the vapor of carbon. The middle band, "near b," was much brighter than the other two, and he was quite satisfied as to its identity with the middle bands of carbon vapor, but the outer bands were so faint that he could not speak confidently concerning them. It will be perceived that this report from Dr. Huggins confirms the observations made by Professor Young, though in the early part of November the comet was too faint to permit the former to determine the position of the outer bands of the spectrum.

At the meeting just mentioned the Astronomer Royal called attention to the fact that the longer axis of the comet was directed almost exactly towards the sun, and that its head and nucleus were turned away from that luminary. This, he remarked, appears to be the rule with nearly all the smaller class of comets. "Unlike the sheep of little Bo-Peep, they carry their tails before them, and not until their smaller fan-shaped appendages have been well warmed by the sun's rays do they begin to shoot out large tails in the other direction." The aspect of the comet, according to a drawing made by Mr. Carpenter of Greenwich, was that of "a somewhat shuttlecock-shaped nebulous haze, with two wings of much fainter light, extending on either side, giving a flattened appearance to the head of the comet." A drawing made by Dr. Huggins agreed quite closely with the above. He thought he had detected a minute but distinctly marked nucleus in the head of the "shuttlecock."

Corrigenda. — The *American Journal of Science and Arts*, for December, reprints Professor Young's article on "An Explosion on the Sun," but accidentally transposes Figures 3 and 4, which makes one of the foot-notes rather "blind." In the original article, by a slip of the pen, the great prominence which so strangely "blew up" was said to be "on the eastern limb of the sun," whereas it was actually on the *western* limb.

"WHAT'S IN A NAME?"

The progress of scientific discovery in these latter days has called for large additions to our stock of English words. A glance at almost any page of "Webster's Unabridged" will show that a considerable fraction of the words are of this recent and technical character, and there are countless others that do not gain admission to a general dictionary of the language, however complete it may be. Each science has its special nomenclature, comprising, it may be, many thousands of words, only a scattered few of which find their way into general literature, or are often heard outside of "professional" circles.

What these technical names shall *be* is sometimes a perplexing question. It not unfrequently happens that the same thing — an animal or a plant, for instance — has several godfathers, and it may be difficult to decide which name is to be adopted. The first one given, if it can be ascertained, is entitled to the most respect; but the others often have to be mentioned as *synonyms*, in order that there may be no doubt as to the exact thing that is meant.

In the science of chemistry, names are thus multiplied by the rival *systems* of nomenclature which, in the last few years, have caused such a vexatious "confusion of tongues" in text-books and other chemical literature. "A rose by any other name would smell as sweet," and the odor of sulphuretted hydrogen is the same, whether we call it by that old-fashioned appellation, or designate it as hydrosulphuric acid, sulphydric acid, sulphide of hydrogen, hydric sulphide, or hydrogen sulphide, all of which are found in recent books. An ideally perfect nomenclature is unquestionably a desideratum, but a comparatively imperfect one, if universally accepted, would be far better than this Babel of antagonistic systems. Even the same names have their rival orthographies. *Oxide* and *oxyd*, *chloride* and *chlorid*, etc., have their respective advocates; and so with *glycerine* and *glycerin*, *benzole* and *benzol*, and all their kindred in *-ine*, *-ole*, *-yle*, *-one*, etc. When these competing systems of naming and of spelling are carried into those provinces of organic chemistry where each single title for a compound is a polysyllabic monster of "learned length," it is even worse. *One* such name as dimethylpropylcarbinol, or methylethylamylamine, or triethylphenylammoniumhydroxide (and these are merely average specimens taken at random) is quite enough for tongue, or pen, or memory, without the introduction of "synonyms."

How far shall *personal* names be admitted to scientific nomenclature, is a question which has more than once been raised. In botany, and the various divisions of natural history, such names have been extensively introduced, and a fearful array of Latinized hybrids has been the result. The "Flora" of any manual of botany bristles with such specific designations as *Smithii*, *Greenii*, *Buckleyi*, *Skinneriana*, *Muhlenberghii*, *Schlechtendahlii*, *Scheuchzeria*, and the like. That pretty flower, the *Eschscholtzia Douglasii*, bears the burden of two such honorary tributes, owing the former and more terrible one to the German botanist Eschscholtz, whose Californian researches have made his name as famous as its orthography is marvellous. But fortunately the vast majority of these botanical terms are not in every-day use. The fair and fragrant blossoms have simpler and more euphonious names for our familiar discourse, and their scientific appellations are seldom heard except in scientific circles. And the learned names of beasts, birds, insects, shells, etc., are for the most part similarly restricted in their use.

In astronomy, several attempts have been made to give personal names to planets, but it is now settled by general consent that this shall not be done. The planet *Uranus* was for many years generally known as *Herschel*, especially in Continental Europe, and Herschel himself wished to call it the *Georgium sidus*, in honor of his patron George III., but the mythological name prevailed; and so with *Neptune*, which was at first called *Leverrier.* When Hind gave the name *Victoria* to one of the asteroids he discovered, some astronomers opposed it as a dangerous precedent, although there was a Roman goddess Victoria. He succeeded in carrying his point, but Tempel was not allowed to christen *his* planetoid *Maximiliana*, and *Cybele* was substituted. If it had become the fashion to call planets after their discoverers, we might have such names among the starry host as Pogson, Ferguson, Schiaparelli, Tietjen, Watson, and Peters; and if the names of patrons and rulers were admitted, some celestial orb might have been known as Louis Napoleon or Thiers, Buchanan or Grant. This would have been as ridiculous as the "reconstruction" of the constellations proposed by Weigel, of the University of Jena, in the seventeenth century. He wanted to substitute modern heraldry for the ancient mythology, by placing in the zodiac the escutcheons of twelve illustrious houses of Europe, and metamorphosing the other leading asterisms in the same way; but the attempt proved as futile as that of the pious Julius Schiller, in 1627, to Christianize the heathen heavens by transforming Cassiopeia to Mary Magdalene, Perseus with Medusa's head to David with the head of Goliath, the zodiacal Aquarius to John the Baptist, and so on throughout the skies.

The subject is a tempting one, but our limits will not permit us to enlarge upon it. We will only add that the recent tendency to make use of personal names in the formation of technical terms in physics appears to us as objectionable as the astronomical vagaries just noted. We believe that Faraday proposed the word "franklinization," and "faradization" has recently been elaborated by somebody or other. *Voltaic* and *galvanic* are too well established to be repudiated, but we protest against enlarging the list of such derivatives. We do not desire to have telegraphing come to be known as "morsization," or to hear some new electrical process called "snooksization" or "stubbsization" in honor of its originator. Such words are readily adopted into the dialect of quackery, as "faradization" appears already to have been, and that would be a sufficient objection to them, even if we were not obliged to condemn them on philological grounds and also as being offensive to good taste.

A NEW AND SIMPLE TEST FOR PETROLEUM.

At the session of the American Science Association, in Indianapolis, Prof. Vander Weyde described a new test for the adulteration of kerosene, which seems to be of practical value. It is founded on the fact that all vapors given off by petroleum are combustible, and that if any kerosene or other preparation from petroleum gives off a vapor at the standard temperature of 110 degrees, it is not necessary to try whether it will burn, but merely to collect it in a proper vessel, by which we gain the additional advantage that we may measure the quantity of the vapor, while none of it can be lost by air currents incidentally passing over the surface of the liquid. He takes, therefore, a glass tube, closed at one end and open at the other, and fills it with the petroleum to be tested, then closing the open end with the finger inverts it in a vessel with water warmed to 110 degrees by mixing hot and cold water, and kept at that temperature by occasionally adding hot water. Any vapor given off will collect in the closed upper part of the tube, displacing the oil downward. The amount of this gas will be a comparative test of the different qualities of oil, and the tube may be graduated in order to measure the amount. This method is not subject to the discrepancies found in the usual way of testing, in which an impure and dangerous quality of oil may be made to appear better than it is by slow and gradual heating; and in which a light draft of air may carry off the vapors as soon as developed, so that it becomes impossible to ignite them. This new method gives freedom from the danger of using fire, more accuracy, a trustworthy means of measurement, and no chance for deception.

EDITORIAL NOTES.

Transparent Colors for Glass or Mica. — A correspondent has lately sent us an inquiry as to the best colors, and mode of applying them, for the painting of glass slides for magic lanterns. A writer in a recent number of the *Zeitschrift für Färberei*, states that the aniline colors are especially adapted for such purposes, as they have great intensity of color even in very thin films. The process he recommends is to prepare separately an alcoholic solution of bleached shellac or sandarach, and a concentrated alcoholic solution of the aniline color; then to add the latter to the former before using it, warming slightly the glass to be painted. The same authority states that colored solutions of guncotton in ether may be used for the same purpose, the coloring matters being dissolved in alcohol and ether. The addition of some turpentine oil increases the elasticity of the collodion fibre, which, if the liquid be applied cold, can be removed entire. It may then be cut into any pattern, and again attached to glass or mica. This latter process would sometimes be a convenient one.

The Separation of Chlorine, Bromine, and Iodine. — In a late number of Fresenius' *Zeitschrift für Analytische Chemie*, the following process is given for the separation of the above elements. The three elements are precipitated as silver salts. The mass while moist is heated with a solution of sesquicarbonate of ammonia, which is prepared by dissolving transparent crystals of carbonate of ammonia in 9 parts of water, and to each 10 cubic centimetres of the solution 5 drops of a 10 per cent. solution of ammonia is added. If the carbonate of ammonia is effloresced, a drop of the ammonia solution, is added for each cubic centimetre of the solution, and it is allowed to stand for a day in an open vessel. To the moist mixture 80 or 100 times its weight of the above solution is added, it is then boiled for a few minutes; the residue, consisting of iodide and bromide of silver, is then washed by decantation and treated with a solution containing 5 per cent. of ammonia, which dissolves the bromide of silver and leaves the iodide. The author has proposed this as a quantitative method, but the results as given by him do not seem to be sharp enough for successful employment, as both the iodide and bromide are slightly soluble in the sesquicarbonate of ammonia, and the iodide of silver is slightly soluble in ammonia.

Test for the Detection of Small Quanti-ies of Sulphur in Coal-Gas. — Dr. Wartha orms, first, before the blow-pipe, in the loop of a latinum wire, a bead of pure soda, and next passes his bead over the edge of the gas flame, after which he bead is held in the interior of the flame in order to deoxodize the sulphates and sulphites of soda nto sulphuret of sodium; the bead is then trans-erred to a porcelain basin, crushed, and some nitro-russide of sodium added, whereby the smallest race of sulphur will be detected. This reaction is fty times more sensitive than that upon silver foil; nd the test can be performed in about three min-tes, whereas Dr. Vogel's sulphur-copper reaction or this purpose takes four hours.

Good Kerosene and a Tough Skull. — It is efreshing to meet with a case like that which an xchange reports from New Bedford. "An old entleman, seventy years of age, fell down stairs ecently with an armful of books and a lighted erosene lamp. The lamp was shattered, but there as no fire. The old gentleman's head struck gainst and completely demolished a wooden pail, ut his skull remained in shape." Our aged friend as fortunate, both in regard to the quality of his erosene, and the thickness of his skull. We trust, owever, that his good luck will not make septuage-arians careless in going up stairs heavily laden ith lamps and literature, for such a happy com-ination of circumstances is not likely to occur equently.

ATOMS.

The electric girdle that will soon surround the lobe has had another link added to it by the tele-raph cable recently laid between Batavia, in Java, nd Port Darwin, Australia; and messages can ow be sent through from New York to Australia. — he fishermen of a single English town, Lowestoft, aught in two days twenty-two million herrings, orth at the retail price of a penny apiece, £91,666; ut, as it was impossible to take care of them all t time, many tons had to be sold for manure. — r. Needham, in the *Journal of Materia Medica*, lvises the use of the fluid extract of clover in can-er, and from the testimony of other medical jour-als it would appear that it has a far better claim ian cundurango to be considered a specific in that sease. — Gas is shortly to be introduced into okohama and Yedo, in Japan; the plans for the orks having been made by French engineers, and ie contract for their construction taken by a firm Glasgow, Scotland. — It is said, on excellent au-ority, that calomel applied dry once or twice a y to tumid and tender hæmorrhoids rarely fails cure them in a few days. — In Manila, twenty-ve thousand women and children are engaged in ie manufacture of the well-known Manila cigars, average wages at seven cents a day. — The *Rail-ad Gazette* shows that the idea of heating railway rs with steam from the locomotive boilers is im-acticable, as the best boilers yet made are barely pable of supplying sufficient steam for driving the igine. — Real estate is "going down" in Hyde ark, Pa., for the giving way of the top of a coal-ine under that village lately caused an area of enty acres to sink some two feet below its former vel, and there is danger of a further "depression" prompt measures are not taken to prevent it. — rofessor Wood, of King's College Hospital, is said to meeting with success in the treatment of pyæmia keeping the patient's body in a carbolized at-osphere, together with the internal administration the sulphocarbolate of iron. — In a single day ore than a hundred thousand bushels of oysters ive been taken from the Chesapeake Bay, which the greatest oyster-bed in the world, and is said be inexhaustible. — Dr. P. F. Whitehead, after effectual efforts with other agents, found that thirty grains of chloral hydrate immediately and permanently relieved a case of hiccough which had continued for thirty-six hours; and Dr. T. L. Leavitt also reports several cases of the same disorder promptly arrested by chloral. — The London and Northwestern and the Lancashire and Yorkshire, two companies which hold about one-seventh of the railway capital of Great Britain, have been consolidated with nearly $500,000,000 capital. — It is said that cod liver oil may be taken as agreeably as a sardine, if a small quantity of salt be first placed on the tongue; and castor oil may be made perfectly palatable by rubbing two drops of oil of cinnamon with an ounce of glycerine and adding to it one ounce of the castor oil. — To detect traces of iodine, M. Pellogio places the suspected solution, mixed with starch paste, in a porcelain dish, and then passes an electric current through it; when, if iodine be present, it is indicated by a blue coloration at the positive pole. — The new Opera House, in Providence, R. I., which is considered a model structure of its class, was the work of Mr. John A. Fox, a young Boston architect. — The 117th asteroid, to whose discovery by Dr. Luther, we referred in our last, was detected two days earlier by M. Borelli at Marseilles, and "Silliman's Journal" says it has been named *Lomia*, which we suspect to be a misprint for *Lamia*. — In an otherwise well-written article in the London *Building News*, we read that "the specific gravity of iron is 3.79, and that of lead 11.35, or almost exactly three times that of the former metal" (the specific gravity of *Yankee* iron is about 7.79), and the statement, though made some month or two ago, has not yet been contradicted.

Pharaoh's Serpents. — These, once so largely popular toys, have been almost entirely abandoned, owing to the poisonous character of their constituents and of their fumes. Dr. Puscher now announces that a mixture of 2 parts of bichromate of potassa, 1 part of nitrate of potassa, and 3 parts of white sugar will produce the effect of the serpents without the attendant inconveniences. He recommends the mixture to be done up in paper or tin foil cones, as the original "serpents" were; and also the addition of some balsam of Peru to perfume it.

Remarks. — We have prepared some of the composition as given above, and find when ignited it does not give a "serpent" at all comparable with those resulting from the sulpho-cyanide of mercury. The serpents are of a green color and break very easily. In order to make them, the materials should be mixed and then slightly moistened; they may be then moulded into cones, which should be several times larger than those made of sulpho-cyanide of mercury.

Thanks. — Mr. N. B. Morrison, of Odin, Ill., sends to the Journal a fine list of new subscribers, and writes as follows: "I take pleasure in sending the following list of new subscribers to your most valuable journal, as I am certain the amount of instructive and interesting information each one will obtain will be worth many times the cost of subscription." We print this as a specimen of many letters we receive, in which our friends send the names of new patrons which they take the trouble to obtain, without desiring premiums or discounts. They work for the Journal because they feel that its influence is good, and that its instructions are needed in every family.

The American Journal of Science and Arts. — Every friend of science in the United States ought to aid in the support of this excellent journal. It is an honor to our country, and is received in Europe and throughout the world as the representative of American scientific culture. It is devoted to pure science, and as journals of this class are not supposed to be of interest except to students and men engaged in scientific research, they usually receive inadequate support. The view taken of these journals by cultivated men even is a wrong one. Of course, "Silliman's Journal," as it is popularly designated, contains much that is not of general interest, but it also contains much that all intelligent readers can understand, and which is very important and instructive. But if it is not read at all, our men of wealth and culture ought to become its patrons, as by so doing they become the patrons of American science, and give encouragement to those who are laboring night and day to extort from Nature those great secrets, which have so important a bearing upon national wealth and individual happiness. The editors of the journal are Professors Dana and Silliman, aided by Professors Gray and Gibbs of Cambridge, and Professors Newton, Johnson, Brush, and Verrill of New Haven.

LITERARY NOTES.

Messrs. Putnam and Son, of New York, have published *Lectures on Natural Theology*, delivered before the Lowell Institute, Boston, by P. A. Chadbourne, A. M., M. D., of Williams College. The author certainly possesses a versatility of talent not usually found among our educators. He appears to be equally at home, whether he be at the head of an Agricultural College, or President or Professor in other Colleges; we hear of him at one time as the leader of a party of students to the icy shores of Greenland, and at another as botanizing among the everglades of Florida, or collecting minerals among the mountains of Brazil. One season he is among the silver miners in Utah, the next he is exploring the cliffs and valleys of the Sierra Nevada, or dredging in San Francisco Bay. As naturalist, chemist, botanist, metallurgist, agriculturist, and theologian, he is well qualified to consider and discuss the relations of science to theology as taught in nature; and in the lectures before us he has performed a difficult work in a creditable manner. The theme is one which has occupied the minds of some of the greatest men that have ever lived, and many able treatises have been written, but there is a freshness and originality in Professor Chadbourne's book which commands the respect of scholars, and holds the attention of general readers.

The *Twelve Lectures on Agricultural Topics*, delivered before the Lowell Institute, Boston, by Alexander Hyde, have also been gathered into a volume. They were well received at the time of their delivery, and the author has revised and enlarged them so as to form a general treatise upon soil cultivation. It is the work of a practical man, and contains many suggestions of much value, conveyed in a style which is simple, direct, and forcible.

Dr. J. H. Klippart, Secretary of the Ohio State Board of Agriculture, has sent us his Report upon the Agricultural Survey of the State. It is a very important and interesting document, and one which must be of great service to the agricultural interests of Ohio. It discusses in a very clear manner the nature of the soils, meteorology, forests, etc., of the different counties, and also has much to say regarding plant food and the growth of plants.

A Southern lady, Miss E. L. Howard, of Kingston, Georgia, undertook several years ago the task of translating Professor Ville's *Lectures upon Manures*, delivered at the experimental farm at Vincennes, France. Difficult as the undertaking was for one having but limited acquaintance with chemical terms and theories, she accomplished the work admirably, and we are pleased to notice that a third edition has just been issued at Atlanta. Miss Howard has conferred a great service upon agriculture by translating this little book, as it is a treatise full of important facts and suggestions.

Messrs. Hurd & Houghton have issued *Macaronic Poetry*, by J. A. Morgan, A. M., a collection which classical scholars have often longed to see, and which deserves a permanent place among the "Curiosities of Literature."

The Harpers publish for the holidays, Morris's *Dogs and their Doings*, and Du Chaillu's *The Country of the Dwarfs*, both of which are at once attractive and instructive, and may be cordially recommended as presents for the young folks; and the same may be said of Abbott's *Water and Land*, the third volume of the excellent series of "Science for the Young."

The Appletons add to their list of educational works a *Text-book of Geology*, and a *Text-book of Zoölogy*, both by Prof. H. A. Nicholson, of University College, Toronto. The author's views upon elementary teaching in the sciences are sound and sensible. He has treated his subjects in a purely scientific spirit, without attempting to lend them "any false glitter or embellishment." We believe that every true teacher will welcome books prepared on such principles.

Messrs. Chatfield & Co., of New Haven, have gathered up the first five numbers of their "University Scientific Series" in a neat volume under the title of *Half-Hours with Modern Scientists*. They have also issued President Woolsey's two sermons, *Serving our Generation, and God's Guidance in Youth*, and an *Elementary Music Reader*, by B. Jepson, intended for use in public schools.

Medicine.

HYDRATE OF CHLORAL AS AN ESCHAROTIC.

SOME time ago a correspondent of the *Scientific American* made the following statements regarding a new application of hydrate of chloral. We have not learned that any reliable experiments have been made with the agent, as regards its suppurative or rubefacient effects, but it would be interesting, and perhaps important to test its value in this direction.

Some months ago, when preparing a solution of the chloral, I held the stopper of the bottle containing it between my lips for a few moments. A small quantity of the crystals was sticking to it, and, on replacing the stopper, I found a red spot on my lower lip; this spot became quite sore, and continued so for several days. This fact led me to experiment with the chloral. The result is, I have found it to be one of the best, possibly *the best*, suppurative agent known. According to the time it is left on the skin, it becomes a perfect rubefacient, irritant, suppurative, or even escharotic.

I have given it fair tests personally, and strongly recommend its use; but *externally* only. When applied, the burning is precisely like that produced by a cataplasm of strong mustard; but, at the same time, a sedative action is perceived, which somewhat neutralizes the smarting, while it does not prevent an excessive irritation of the skin. It does not blister, but the part the choral has been applied to becomes exceedingly inflamed, and more or less swollen; and according to the length of time of application, shows a merely reddened skin, or a suppuration of several weeks' duration.

I give you my mode of application: Take a piece of fresh adhesive plaster, of the size wanted, and crush fine, on its surface, with an ivory spatula, enough of the crystals of the chloral to powder the piece of adhesive plaster quite evenly; use the edge of the spatula to take off the chloral where it is more than a mere dust in thickness, but distribute evenly, leaving one third of an inch margin for adhesion: heat the back of the plaster for an instant only, and apply. Leave it on about half an hour as a rubefacient, six hours as an irritant. To produce suppuration, put the chloral on the plaster in larger quantities, and leave on from twenty-four to thirty-six hours; on its withdrawal, apply a stimulating salve, and afterwards heal with cerate. For an escharotic effect, apply the chloral, thickly spread, and, after twelve hours, repeat the application, if necessary.

It is surprisingly active as a suppurative, and, for this reason it will not be prudent to apply it to any part of the surface of the abdominal cuticle, as, in one case under my inspection, having been left on too long, it occasioned a deep ulceration that was difficult to heal.

In this new mode of use, the chloral is truly invaluable; it is easily applied, cleanly, and perfectly reliable. It is a first-class derivative in facial neuralgia, ear-ache, headache, and any affection of the eyes; a small plaster, of a half inch diameter, that can be hidden by the hair, being sufficiently active, if prepared with enough chloral, to irritate in a very short time. I earnestly recommend the above facts to the notice of the medical faculty.

THE SMALL-POX AND ITS LESSONS.

THE Board of Health at Lowell have published a report upon the epidemic of small-pox, with which that city was recently visited.

The Board called to their aid a committee of seven "consulting physicians," and their report, drawn up by Drs. Nathan Allen, Gilman Kimball, and J. W. Graves, is appended to the document. The following remarks, with which the physicians close the record of their doings, are suited to other latitudes than that of Lowell, and it would be well if they could be published and pondered through the length and breadth of our land:—

This sad record of disease and mortality has its lessons of admonition and instruction. When this epidemic first made its appearance, our people were, unfortunately, but poorly protected against its ravages. There had been no general vaccination, by official authority, for six or seven years, and, in the meantime, an entire change had taken place in nearly one third of our inhabitants. Besides, the mixed character of our population, composed as it is largely of young persons, renders it more necessary that a thorough course of vaccination, by official order, should be resorted to frequently, as a safeguard against the disease. Again, our Boards of Health, as usually constituted, are not chosen with any particular reference to special qualifications to insure intelligent and efficient action, are changed almost entirely every year, and no compensation is allowed for services thus rendered. The medical profession, as such, has not been represented upon the Board for many years, and even the City Physician is not a member of it. We have a superintendent of streets, of buildings, of city scales, and of *burials*, even, but no superintendent of public health. Had our city been provided with such an officer, or had the advice of some of our oldest and most experienced physicians been followed, at the time, we believe the present epidemic would have been suppressed in its incipient stages. The city expends money liberally, every year, to protect property and make improvements of various kinds, but nowhere do we find any appropriation directly for the prevention of disease, or the preservation of human life. No small amount of sickness and mortality occurs here every year, caused by nuisances and various other sources, which might easily be prevented by the proper employment of hygienic and other agencies. The City Physician and City Marshal are, to be sure, charged in the ordinances with certain health duties, but they always have enough else to engage their time and attention, and neither is chosen with any special reference to qualifications in this particular department of public service. Neither can it be expected that such important duties will be properly performed, under a sense of personal responsibility to the public, without the appointment of suitable officers, accompanied with an adequate compensation.

How frequently, of late, has the whole community been shocked by the loss of life, in the fall of some building, some railroad disaster, explosion, or by the wreck of some vessel at sea; but here in our midst, this very year, have the lives of one hundred and seventy-five individuals been quietly sacrificed, which, apparently, might and ought to have been saved! Shall we not profit by such sad experience in the past, and ought we not now to prepare for another great epidemic, with which our country is seriously threatened the coming year? Let the suggestion be seasonably heeded.

ON THE ESTIMATION AND DETECTION OF SUGAR IN DIABETIC URINE.

THE first circumstance that attracted notice was the ordinarily high specific gravity of diabetic urine; yet some specimens loaded with sugar had almost a normal specific gravity. This was difficult of explanation, unless solids may be present in liquids in different molecular states. Ordinary urinometers are not to be trusted, some being correct within ten or fifteen degrees. The presence of torula cerevisiæ is not to be regarded as any proof of the existence of sugar. No less than three kinds of fungi are to be found in diabetic urine, and all three without a trace of sugar. With reference to the different kinds of sugar found in diabetic urine there was—(1) the ordinary grape-sugar; (2) a variety resembling misilæ; (3) one differing from both these, and remarkable in several particulars. Passing to the chemical tests, the author remarked that if carbonic acid was to be collected for the purpose of estimating the quantity of sugar, it was better collected over oil than any other way, and if great accuracy were required, he suggested allowing the carbonic acid to pass into baryta water, the precipitate being weighed as a sulphate. 1. Dr. Roberts, of Manchester, had suggested taking the specific gravity both before and after fermentation, and from this estimating the amount of sugar present. The test gave very variable results. At one time very accurate, at another very inaccurate, results had been obtained. 2. The copper test was valuable, although there were several bodies that interfered with its action, and, as a quantitative test, Dr. Tidy had very little opinion of it, as it was impossible to mark the exact point where the blue color had disappeared. 3. Moore's test: The dark color due to melassic acid produced when diabetic urine was boiled with potash solution. A series of solutions were placed on the table containing different but known quantities of sugar, but in each the same quantity of alkali. They ranged from 0.25 gr. of sugar to 2.0 gr., and the difference of tint was perfectly marked. Dr. Tidy proposed this, an adaptation of Vogel's method, for estimating sugar. The method of working was as follows: A potash solution containing 1 gr. of potash to every septem (7 gr.) of water having been made, take 10 septems of the urine, add 10 septems of the solution; boil for one minute, dilute with distilled water in a four-ounce vial (similar to those used for the test solutions), and then compare with the test solutions labelled as containing known quantities, until the exact tint is found. The small quantity of urine employed does not color the water so as to interfere with the test. If any precipitate is produced by boiling, it must be filtered. If the tint was more than that indicated by two-grain standard bottle, it must be marked and diluted. The experiment made gave:—

$$\left.\begin{array}{l}1.25 \text{ gr. in } 10 \text{ septems}\\ 12.5 \text{ gr. in } 100 \quad \text{"}\end{array}\right\} = 17.86 \text{ per } 1{,}000 \text{ gr. of urine.}$$
$$12.5 \text{ gr. in } 700 \quad \text{"} \qquad = \text{about } 8.6 \text{ per oz.}$$

Dr. Tidy proposes to get rid of the trouble of the standard solutions by using gelatine colored of different tints, as standards for comparison.—*Medical Times.*

ICE AND COLD WATER AS LOCAL APPLICATIONS IN SCARLATINA, CROUP, ETC.

DR. CARSON, in a series of able papers in the *Philadelphia Medical and Surgical Reporter*, calls attention to the happy results following the use of ice and cold water in scarlatina, diphtheria, croup, quinsy, etc. The good effects of ice-water applications to the throat externally, and ice in substance as a gargle to the throat, were almost magical. Fatality was vastly lessened, recovery was rapid, and sequelæ were uncommon. The cases of scarlatina were not selected, but all were given,—malignant, anginose, and simple. Dr. C.'s observations as to the effects of these agents run through some twenty or more years. As his experience with them has increased, so has his faith. He reasons that the diseases in question are originally local in their action, the systemic trouble being secondary. Combat and arrest the local trouble, and the systemic disorder will be prevented or lessened. He condemns the practice which consists in caustics, astringents, irritants, and poultices to the throat and neck, as but adding fuel to the fire. The indications are to cool the burning throat, to con-

·inge and tone up the blood-vessels, and lessen the ·er. All this is accomplished by allowing the tient to suck ice, to gargle the throat with ice-ιter, and by enveloping the neck in bags of ice, d by cold affusions to the general surface. This actice is to be kept up steadily throughout the ιole course of scarlatina. This, together with pport by nourishment, is all that need be done in e mildest as well as the severest cases. Albumi-ria and enlarged glands do not contra-indicate e use of ice and ice-water. Dr. C. contends that ere is no danger of retrocession of the disease un-r the use of these agents. He gives over one ndred cases of scarlatina in one year, all treated these means, with not a single fatal result.

The same treatment is equally successful in diph-eria, membranous croup, and quinsy. It is re-arkable that our text-books on practice and the seases of children have given hardly a passing no-ιe to these simple therapeutics in the management diseases so dangerous to life.

HYPOSULPHITE OF SODA IN VARIOLA.

In an epidemic of sixteen cases of small-pox on ιard of the U. S. S. *Benicia*, at Yokohama, Dr. 'm. A. Corwin, Asst. Surg. U. S. N., states (in ιe *Medical Record*) that not being able to get the *sulphite* of soda, "with the concurrence of Surgeon elson the *hyposulphite* was employed in drachm ses, and we had every reason to be gratified with ιe result. This treatment, used in the premonitory ver *only*, was commenced with the *fourth* case, and s effects carefully watched. They were those of ι *alterative*, mild *hypnotic*, and *laxative*; its admin-tration being in most cases followed by a subsi-ence of the fever, a tardy or incomplete develop-ιent of the eruption, and relaxation of the bowels ith watery stools. Upon the full development of ιe eruption the remedy was generally discontinued, ιd a supporting *régime* adopted, — egg and brandy ixture, with easily digested food. The good effects the salt were generally manifest after the first ose; the patient losing the heat and dryness of ιe skin, expressing himself as much more comfort-ble, and passing a good night. In two or three of ιe cases, the eruption was delayed from twelve to venty-four hours after the usual time for its ap-earance, and in one patient the eruption consisted irregular erythematous patches with successive ops of minute vesicles in the flexures of the limbs. he average duration of the first three cases (fatal) as six days. Of the cases that recovered, one was *alignant*, the rest of all degrees of severity. Their verage duration was *twenty days*. What I particu-ιrly wish to have noted is the fact, that in direct roportion to the early and free use of the remedy, ιally harmless for evil while so potent for good, as the disease ameliorated and its average dura-on shortened, and this in an epidemic of more than sual severity."

MEDICAL MEMORANDA.

The Formation of Sugar in the Liver. — 'rof. J. C. Dalton, in a paper on this subject, read efore the New York Academy of Medicine, de-cribes an extended series of experiments upon dogs, ιade with a view to settling the question whether ιe hepatic sugar which appeared with such rapidity fter death existed in minute quantity in the organ efore death or was entirely a *post mortem* produc-ion. As the most delicate test for glucose, he se-ected Fehling's solution, which is a double tartrate f potash and copper dissolved in an alkaline solu-ion, containing in a given volume a given quantity f copper. He experimented with twenty dogs, sing this test; in four cases the liver was placed n boiling water, and in sixteen in alcohol immedi-tely after removal from the body: the longest time that elapsed from the separation to the immersion in boiling water or alcohol being thirteen seconds, and the shortest time six and a quarter seconds, and in every instance the final watery solution gave a decided sugar reaction.

The conclusions to which Prof. Dalton comes, as the result of these experiments, are the following: —

I. Sugar exists in the liver at the earliest period at which it is possible to examine the organ after its separation from the body of the living animal.

II. The average quantity of sugar existing in the liver at this time is at least two and a half parts per thousand.

III. The liver-sugar thus found does not belong to the arterial blood with which the organ is supplied, but is a normal ingredient of the hepatic tissue.

The Mullein Plant. — Mullein is common in the United States, growing in recent clearings, along the sides of roads, in neglected fields, etc., flowering from June to August. According to the *Half-Yearly Compendium*, the plant has valuable medicinal properties. The leaves and flowers are the parts used. They have a faint, rather pleasant odor, resembling that of a mild narcotic, and a somewhat bitterish, albuminous taste, and yield their virtues to boiling water. Mullein is demulcent, diuretic, anodyne, and anti-spasmodic. The infusion is useful in coughs, catarrh, hæmoptysis, diarrhœa, dysentery, and piles. Its diuretic properties are rather weak, yet it is very useful in allaying the acridity of urine which is present in many diseases. It may be boiled in milk, sweetened and rendered more palatable by the addition of aromatics, for internal use, especially bowel complaints. A fomentation of the leaves also forms an excellent local application for inflamed piles, ulcers, and tumors. The leaves and pitch of the stalk form a valuable cataplasm in white swellings, and infused in hot vinegar or water, it makes an excellent poultice to apply to the throat in cynanche tonsillaris, cynanche maligna, and mumps. The seeds are said to pass rapidly through the intestines, and have been successfully used in intestinal obstructions. They are narcotic, and have been used in asthma, infantile convulsions, and to poison fish. The infusion may be drunk freely. The flowers, placed in a well-corked bottle and exposed to the sun, are said to yield an excellent relaxing oil.

Chloral in Toothache. — Dr. Page, in the *British Medical Journal*, states that for some time past he has employed chloral hydrate, not only as an internal sedative in dental neuralgia and caries, but also as a local application to a carious tooth. A few grains of the solid hydrate placed on a quill-point, introduced into the dental cavity, speedily dissolve, and the pain is either deadened or effectively allayed. A second or third application of the remedy may be necessary.

Action of Medicines. — Dr. Chambers, of London, in his late Harveian oration, made the following remarks on the importance of observing the action of remedies: "To the court of experience we are, one and all of us, called as jurors. There are millions of experiments performed daily by observers who can regulate their conditions. But how are we prepared for turning the experiments to account? What training does the medical student go through which shall enable him to exercise his franchise? I cannot but say that those of us who are teachers in schools have greatly failed of our duties in this respect. I have never yet, as examiner, come across a candidate for diploma instructed in the art of systematically observing and recording the action of medicines. What an awful waste of raw material is here! Surely the chairs of materia medica would be better employed in training a class how to observe than in discussing varieties of cinchona-bark or the shape of senna-leaves — a kind of knowledge which no one ever really gets from lectures, but, if he require it, either from a book or a warehouse."

Koumiss. — The use of koumiss may be regarded as a variety of "the milk cure." Koumiss is prepared in Russia by the fermentation of mare's milk; and a similar substance has been made in England from cow's milk. It is a sweetish, acidulous-tasting liquid, which can be taken in large quantities much more easily than other forms of milk. It is the chief diet of a hardy race on the steppes of Russia, near the lake of Baikal, where it is said consumption is unknown. This exemption attracted the attention of the Russian faculty and of the government. Establishments for the koumiss cure were opened in other parts, and a knowledge of the method of treatment is spreading over Europe.

Treatment of Footsoreness. — The *Lancet* states that the Inspector General has directed that every man suffering from feet blistered by marching is to be taken at evening parade to the medical officer, who should cause him to wash his feet, and then to pass a needle with a worsted thread through each blister, cutting off the thread a little distance outside the blister at each side, and leaving a portion in it. The part is then to be rubbed with common soap, the sock put on and wetted over all prominent points, and the soap again rubbed over them freely. When properly attended to, no man should be unable to march the following day on account of blistered feet, unless the cuticle has actually been removed, leaving a raw surface exposed.

Extract of Meat. — Kemmerich states in the *Deutsche Klinik*, that after administering the extract in the form of soup to animals, he found the mucous membrane of the stomach in a state of active hyperæmia, and especially at those places where the glands secreting the gastric juice are situated. It is to be assumed, therefore, that the use of the meat extract favors secretion of the gastric juice. He found that, under the moderate use of the extract, the pulse is quickened and becomes stronger, and that there is at least a temporary increase in the temperature. Too large quantities are injurious, especially to young and weakly persons, and for adults the average amounts should be only about five grammes in the day, and should never exceed fifteen. When given along with suitable food to persons recovering from exhausting diseases, the increase of weight is more rapid, and the period of convalescence materially shortened. As a stimulant it resembles alcohol and coffee, but has the advantage over them by aiding in building up the structures of the body.

Cundurango in England. — Our government some time ago forwarded a quantity of the cundurango plant to the government of England, in order that its alleged influence over cancer might be tested. A Mr. Davidson, the house surgeon of the Middlesex Hospital, to which some of the drug was forwarded, reports in the *Lancet* that "the results plainly show that cundurango is as futile as any of the cancer-cures which have preceded it. It was used in four cases: 1. In an ulcerated epithelioma of the roof of the mouth. 2. In primary cancer of the penis, and secondary injection of the lymphatic glands of both groins. 3. In an ulcerated epithelioma of the scrotum. 4. In an ulcerated scirrhus of the female breast. In all these cases the cundurango had positively no effect upon the progress of the disease."

Adulteration of Lard. — A writer in the *Canadian Pharmaceutical Journal* says that he lately obtained a quantity of lard from a respectable pork-dealer. It was beautifully white; indeed, he had never seen an article that looked better. His first trial of it was in preparing ointment of nitrate of mercury. The color, when the mercurial solution was added, was the reverse of citrine, indeed decidedly saturnine, developing in a short

time to a full slate color. Surprised at this unprecedented result, the usual precautions having been taken as to temperature, etc., the lard was suspected, and on examination was found to contain a large proportion of lime. Some time after, being in conversation with a lard renderer, a hint was dropped as to the relation of lime to color, when the information was confidentially imparted that a common practice among lard dealers was to mix from two to five per cent. of milk of lime with the melted lard. A saponaceous compound is formed, which is not only pearly white, but will allow of the stirring in, during cooling, of 25 per cent. of water. So much for appearances.

HYDROPHOBIA FOLLOWING THE BITE OF A CAT. — Dr. Brumwell reports in the *British Medical Journal* a fatal case of hydrophobia. The patient, a clergyman, aged 32, was bitten in the hand by a cat, which was believed to be mad, on May 14, 1871. On August 10, symptoms of the disease developed themselves, and on the fourth day of the attack death occurred. The symptoms did not differ from those usually presented by hydrophobic patients. There was good reason to believe that the cat had been bitten by a mad dog a short time before she bit the patient.

CAMPHOR. — When the mucous membrane of the nose, frontal sinuses, etc., is affected by catarrh, a strong solution of camphor frequently and for some hours snuffed up the nose, and five or six drops taken internally on a lump of sugar at first for every ten minutes, then every hour, will usually put a stop to the affection. Ordinary cold and even influenza, if treated in this manner at the *very beginning* of the attack, are generally controlled by the same treatment.

Attacks of incessant sneezing and profuse running of the eyes and nose will generally yield to a strong solution of camphor diligently sniffed up the nose. In summer diarrhœa no remedy is so efficacious as camphor, if employed at the very commencement of the disease; later it is without effect. Its influence over cholera is equally remarkable. Dose: six drops of a strong alcoholic solution of camphor, given at first every ten minutes; afterward, as the symptoms abate, less frequently.

USE OF IODOFORM. — This compound, first brought prominently into notice by Bouchardat, is now employed extensively not only for glandular enlargements, but also, owing to its anæsthetic properties, in skin diseases accompanied with intense pruritus; its odor is much more agreeable than that of chloroform, resembling that of saffron. Moretin and Humbert recommend it for internal use as possessing all the advantages of iodine, of which it contains ninety per cent., without any of its inconveniences. It exercises upon the sphincters a local anæsthetic effect so powerful that defecation is sometimes performed unconsciously after its use; it therefore forms an admirable suppository in cases of tenesmus, hemorrhoids, etc. Moûtre's formula is as follows; iodoform, powdered, twenty grains; cocoa butter, one ounce; melt and mix for six suppositories. For frictions, the ointment is used in the strength of one drachm to the ounce of simple ointment.

BRIEF EXCERPTA.

A WRITER in the *Lancet* suggests the use of an infusion of quassia as a dressing for open wounds and ulcers in hot climates or in hot weather. As flies cannot bear the smell of the wood, maggots are thus entirely avoided.

THE following is a good suggestion from a writer in the *Pharmacist*: "To secure dispatch in the mixing of extracts with ointments and cerates, we keep such extracts as belladonna, stramonium, opium, and arnica, in a fluid condition, by means of equal parts of water and glycerine. The diluted glycerine is added to its own weight of extract, and when the latter is prescribed in combination with a cerate, it of course is only necessary to substitute for the extract double its weight of the liquefied article.

PURE lard is readily obtained by rendering it from the "leaf lard" at the proper season; but it is difficult to keep it for any length of time. It is said that this can be best done by the method followed in the Apothecaries' Hall, at Glasgow, Scotland, where the freshly prepared lard is filled into bladders, which are afterwards tied at their necks, and suspended in a cool cellar.

HERR POPP has observed that castor oil turns polarized light to the right, and differs in this respect from all other fats. He also found all the commercial castor oil to contain nitrogen, and finds in these facts supports of his previously expressed opinion, that the purgative properties of this oil are due to a nitrogenated body, probably an alkaloid.

M. LEFEVRE, of Louvain, thinks that excessive smoking causes paralytic mania: because, 1st, nicotine causes in animals progressive enfeeblement of the muscles of motion up to paralysis, and congestion of the nerve-centres. 2d. Analogous symptoms have been noticed in numbers of persons who abuse tobacco in smoking or chewing. 3d. It has been found in all countries that there is a constant relation between the consumption of tobacco and the increase of general paralysis.

PROFESSOR HALFORD, of Melbourne, has been presented with a testimonial, consisting of a handsomely bound book and a purse of 120 sovereigns, as a recognition of the merits of his method of treating cases of snake-bite by the injection of ammonia.

SELECTED FORMULÆ.

A PRESCRIPTION FOR EPILEPSY. — Dr. Brown-Séquard is in the habit of using the following prescription:

℞	Potass. iodidi	ʒj.
	Potass. bromidi	ʒj.
	Ammon. bromidi	ʒiiss.
	Potass. bicarb.	℈ij.
	Inf. columbæ	f. ℥vi. M.

A teaspoonful before each meal and three teaspoonfuls at bedtime, with a little water. The medicine should be pushed until anæsthesia of the fauces is produced, and an acne-like eruption appears on the neck, face, shoulders, etc. Continue treatment for sixteen months after the convulsions have ceased, an occasional purgative being given.

FOR CHRONIC CONSTIPATION. — Dr. Bell recommends the following formula: Socotrine aloes, extract of hyoscyamus, of each twelve grains; disulphate of quinine, six grains; sulphate of iron, four grains. Make twelve pills. Of these he recommends one to be taken in the afternoon from four to six o'clock.

FOR CHAFES. — The *Pacific Medical and Surgical Journal* recommends two parts of powdered soapstone and one part of calomel as the most elegant and effective dry application to the chafed skin of infants.

ELIXIR OF CHLOROFORM. — The following elixir of chloroform is recommended by the Pharmaceutical Association at Washington:

℞	Chloroform, Tinct. Opii., Tinct. Camph., Sp. Ammon. Ar. . . .	āā. ℥iss.
	Oil of Cinnamon	♏ xx.
	Brandy	℥ij. M.

Dose: Half a fluid drachm, more or less.

FUMIGATING PASTILLES.

THE *Druggists' Circular* gives the following recipes, both of which are excellent: —

1.	Take Benzoin	2 ounces;
	Balsam of Tolu . . .	4 drachms;
	Yellow Sandal-wood . .	4 drachms;
	Nitre	2 drachms;
	Labdanum	1 drachm;
	Charcoal	6 ounces.

Mix with a solution of gum tragacanth, and div the mass into pastilles, cone-shaped, and dry th in the air. The foregoing is the formula of t Paris Codex.

2.	Take Benzoin	4 ounces;
	Cascarilla	½ ounce;
	Nitre	3 drachms;
	Gum Arabic	3 drachms;
	Myrrh	1 drachm;
	Oil of Nutmeg	25 drops;
	Oil of Cloves	25 drops;
	Charcoal	7 ounces;

All in fine powder. Beat them to a smooth m with cold water, q. s., and form into small cones a dry in the air.

SKIN-GRAFTING. — Dr. Chambers, of London, his late admirable Hunterian oration, thus allu to this interesting subject: "The becoming co scious of these invisible angels of death, hou drifting around us, reminds one of the opening that mythical box of evils with which Horace h made us familiar. Yet here too there is a hope germ at the bottom. We have to deal with (let say) an unhealthy stagnant ulcer. We strip out bit of clean skin, not so big as a mustard-seed, fr the patient or a friend, and we plant it among t torpid granulations; it sticks, it unites, it lives, feels, and becomes with its new home one flesh, n to be put asunder. John Hunter had taught us expect this. But, better still, it becomes a cent of new growth. Healthy skin begins to form rou its edges. Praise be to the All-merciful! not on disease, but health also is contagious; better still, is infectious; it has stepped over the gulf of feste ing stagnation, and is sowing growth along th neighboring margin, throwing out peninsulas a promontories to join the parent piece of grafte skin. One who has experienced in his own perso what uphill work cicatrization of a large surface i must be pardoned some exultation at this surgic promise, and may be allowed an Utopian dream o restoration which would throw present success f into the shade. Even the practitioner upon other ailments cannot but feel enthusiasm at the revela tion of this important law of Nature. Does it n promise to explain the hitherto inexplicable bene derived from firing, blisters, mustard, croton-oi caustic potash, and other means of cure by extern sores? It is when the artificial sore is getting we that the benefit arises: as the new healthy tiss shapes itself outside, it infects the diseased par with health."

A DRUGGIST SUED. — A suit was recentl brought in England against a chemist and druggi by a man to whom the former had given some me curial pills, with directions how to use them. Th pills salivated him, and an illness followed, whic the medical man in attendance ascribed to the e fects of the pills. The judge held that the law no was that every person who professed to follow an skilful employment was bound to bring to the exer cise of it a reasonable amount of skill. This ap plied to medical men, but not to chemists and drug gists, who were simply sellers of drugs. If a ma would be so great a fool as to go to a chemist an take any pills that he might give him, it was hi own fault. The matter having been argued at some length, his Honor decided that there was no case for the jury, so that, unless the plaintiff elected to be nonsuited, he should direct the jury to find a verdict for the defendant. The plaintiff preferred a verdict for the defendant, in order that he might be in a position to appeal.

It would be very well for this community if it understood that few apothecaries in this country have any knowledge of the therapeutic properties of drugs. — *Medical Times.*

Familiar Science.

CHEMISTS AND CHEMISTRY.

The idea very generally prevails among parents that their boys may readily become chemists by spending three or four years in some college laboratory, and attending the usual courses of lectures of professors and assistants. Operative or industrial chemists have many applications every year to receive young men into their laboratories, and they are assured by parents that the qualifications of their sons are first-class, as they have graduated at certain technological schools or colleges with credit. The true value of such assistance is well understood, and it is usually declined, often to the great disappointment of personal friends. Another class of applicants press their claims upon the attention of industrial chemists, — that is, boys who wish to learn the business. Parents are often very desirous of *making* chemists of their boys, as the vocation is regarded as quite lucrative or promising. Now, there is much misapprehension regarding this whole matter, and we will preface the observations we have to present by saying that chemists are not *made*, they are *born*. Parents can no more make chemists of their boys than they can make painters or sculptors of them. They may place them in the best schools in this country or abroad, they may spend large sums upon them, but after lavish expenditure of time and money sad failures result. It is equally true, that if a boy is born a chemist, all the efforts of parents to thwart his instincts, or all the endeavors to turn his mind into other channels, will prove abortive. The boy that *wastes* all his spending money in the purchase of sulphur, nitre, acids, alkalies, etc., for the purpose of making experiments, and constructs ingenious apparatus out of the most rough and scanty materials, will be quite likely to continue an experimenter to the end of his days. From such lads have come the Davys, Faradays, and Daltons, who by their discoveries have conferred benefits upon the race which it is impossible to estimate. But such boys are rare, each century producing a few, — enough, perhaps, to push the boundaries of science as rapidly as the welfare of the race requires.

What becomes of the scores of young men that graduate from our schools of chemistry every year? Comparatively few of them are ever heard of after graduation. Some we suppose become teachers; others conclude they have mistaken their calling, and seek more congenial pursuits; and thus they disappear one after another. A chemist, using the term in its proper sense, is one who has a peculiar genius, a special adaptation to comprehend problems and perform labors unlike any others which can possibly engage the attention.

Chemical investigation and manipulation demand a combination of talent seldom possessed by any one individual. Ingenuity, or the facility of devising and constructing, is of the first importance; clearness of perception, patience, a mind naturally logical and mathematical, cleanliness, order, industry, and above all enthusiasm and a love of the work are absolutely essential. To these natural qualities must be added a knowledge of the higher mathematics, and a thorough acquaintance with physics and the principles of chemical philosophy. The schools are incompetent to confer upon young men these requisites; the most they can do is to teach the elements of the science, and carry them through the routine of the general work of the laboratory.

The application of the principles of chemistry to art processes constitutes a branch of chemical labor which but few chemists are competent to carry forward. A man may be a very good theoretical, or even a good analytical chemist, and fail in practical laboratory work. The industrial production of the chemical substances which are employed in medicine, dyeing, bleaching, photography, printing, etc., requires a knowledge of processes which are not usually described in books, and which are not taught in schools. It is very easy in school laboratories to prepare a few ounces of chloroform, or isolate a drachm or two of the alkaloidal principles of opium, but to manufacture economically, in competition with the market, a hundred pounds of chloroform or a hundred ounces of morphia a day, requires a knowledge and skill not possessed by ordinary chemists. There are many little matters connected with the industrial production of chemical substances which are of immense importance, and which are only understood by those who are connected with the labor, and who have become acquainted with them by long and patient experimenting.

The services of ingenious, industrious, practical chemists are always in demand, and will command high prices. It is astonishing how few there are of this class. Those who have apparently the needed education and genius do not possess habits of industry, or their ambition is dwarfed, or they have no executive ability, or business habits. The discipline of our schools of chemistry is not, we fear, what it should be. Listless, lazy, vagabond habits are often acquired, which the pupil finds it hard to shake off when he enters upon the practical work of life. This is most unfortunate, and if possible the evil should be promptly remedied, by introducing such regulations into schools as will keep pupils actively employed during the hours of study.

It is certain that chemistry offers a useful and profitable field of research and labor to the youth who is by nature and education qualified to enter it, and it is equally certain that those who have no more than ordinary abilities, and no positive taste for the work, can only meet with disappointment in that field, and they should seek some other.

BAROMETRICAL MEASUREMENT OF THE HEIGHT OF MOUNTAINS.

It was observed soon after the discovery of the barometer that the column of mercury diminished in height when the instrument was transferred to an elevation, and rose again when the instrument was returned to its former position. This was readily accounted for by the fact that the air was less dense on the top of a mountain than at its base, as the column of air above the mountain was shorter than the column above the valley. Mathematicians at once went to work to determine the law of the variation in the height of the mercury and the relation it bore to the height of the mountains, and formulas were soon proposed by which the height of mountains might be determined. But these formulas were only approximate, and contained many empirical elements. It was reserved for La Place to make the first complete solution of the problem; and even his formulas, although they give very exact results, have certain empirical elements.

The mercurial barometer is the only one that is sufficiently reliable to be used in these determinations. The aneroid is regarded as worthless for this purpose, although some very fair determinations have been made with it. The instrument must be made with extreme care, and should be as light and compact as possible, since every pound added to the load when a man is climbing in the thin upper regions of air increases the toil and fatigue. Prof. J. D. Whitney has had made for use among the higher Sierras of California barometers which are only 27 inches in total length, and read only up to 24 inches. They are compact and portable, and are all that is required for any height above 7,000 feet. The standard barometers in use in this country are mostly made by Mr. James Green of New York. They are cistern barometers, the glass tube being inclosed in a light brass case which carries the scale, and by the aid of verniers variations may be read to the thousandth of an inch. The cistern is made of wash-leather, and by turning a screw which presses against the bottom of it the mercury may be forced to the top of the tube. When this is done the barometer is inverted, and it is always carried in this position or on its side. For transporting it, a wooden case is provided which exactly fits the brass tube, and which in its turn fits into a leather case provided with straps to be worn over the shoulder. Thus protected it may be carried on horseback even at a full gallop. Before starting on an expedition the barometer should be compared ten or twelve times, at intervals of half an hour, with the stationary instrument. This operation should also be repeated upon returning. The instruments should agree with each other within a few thousandths of an inch. If the difference is a constant one, it is most likely owing to one of

the scales being out of adjustment; this should be adjusted, and the comparison repeated.

Everything being ready for the ascent, directions are left with the one who has charge of the station barometer to observe it, together with the thermometer, every half hour until the return. This is necessary in order that if it is desired to determine the height of the timber-line or any other object, there may be synchronous observations for comparison. It is only such that are of any value, because the barometer is continually fluctuating with the hour of the day and state of the weather. Having found the difference in the height of the mercury in the two barometers, the height may be roughly estimated by calling each inch of difference a thousand feet difference in level. This is generally accurate enough for altitudes that do not exceed a few hundred feet. For those that are greater the other corrections become too serious to be neglected. The temperature of the air must also be noted, because when air is heated it is lighter than when cold, and the barometer will therefore stand higher in a cold atmosphere than in a warm one. The temperature of the barometer itself, for the same reason, must be observed. There are also other small corrections to be made, on account of the spheroidal figure of the earth and the diminution in the force of gravity as we recede from the centre of the earth. These corrections will be found tabulated in Guyot's tables, or in Loomis's "Meterology," together with La Place's formulas.

Even when all these corrections have been made, a single observation cannot be relied upon within one or two hundred feet, and therefore it is necessary to make a number if great accuracy is desired.

We venture to recommend to young men, or to girls even, the measurement of hills and mountains, as it is a pleasant and healthful summer occupation. It is quite fashionable in England and on the Continent to measure heights, and there is scarcely a hill or mountain which has not been many times measured by students of both sexes.

In this country we have accomplished but little in this direction. There are a few measurements of the White Mountains in New Hampshire and some of the higher peaks of the Alleghanies, but the Rocky Mountains are as yet almost unmeasured. The few lofty peaks that have been measured approximate closely to 14,000 feet. They are more than a thousand feet lower than the highest of the Alps, as Mont Blanc is 15,780 feet above the level of the sea. Mount Harvard, the highest yet measured of the Rocky Mountains, is but 14,272 feet in altitude. Mount Shasta and Mount Whitney in the Sierra Nevada of California are both higher, but neither exceeds 15,300 feet. The establishment of the government signal stations throughout the country will be of great service in determining altitudes, as the nearest station will always be a convenient reference for a standard of comparison. No doubt, any one wishing to make measurements could make such arrangements with the officer in charge as would enable him to dispense with any station barometer of his own.

All other conditions being the same, the vigor and richness of vegetation are proportionate to the quantity of light and heat received.

THE SARATOGA WATERS.

In a lecture upon Water, delivered in New York, Professor Chandler presents some interesting statements regarding the chemistry and geology of the Saratoga Springs. We make the following extract: —

The common origin of the springs is shown by analysis; all the springs contain the same constituents in essentially the same order of abundance; they differ in the degree of concentration merely. Those from the deepest strata are the most concentrated. The constituents to which the taste of the water and its most immediate medicinal effects are due are: chloride of sodium, bicarbonate of lime, bicarbonate of magnesia, bicarbonate of soda, and free carbonic acid. Other important, though less speedily active constituents are: bicarbonate of iron, bicarbonate of lithia, iodide of sodium, and bromide of sodium. During the great petroleum excitement, a New York capitalist conceived the idea of finding oil at Ballston, so he selected a spot on the margin of the Kayaderosseras Creek, a stream which flows through the village of Ballston into Saratoga Lake. Here this patient but ill-advised seeker after petroleum bored down through sand, clay, and hard pan, fifty-six feet, till he struck the solid rock. He tubed the well down to the rock with an iron tube six inches in diameter, and then continued the boring with a five-inch drill. For a considerable distance the drill passed through the Hudson River shales; then it penetrated the Trenton limestone, then the calciferous sand rock, and probably passed some distance into the Potsdam sandstone. At a depth of 571 feet, a vein of mineral water burst into the well, but, as oil was the object of the search, it was not heeded. Finally, our zealous borer was spared further labor in this direction by the steel reamer, which became so firmly fastened in the rock, at the depth of 651 feet, that it could not be extricated. No oil making its appearance, and further progress in the well being out of the question, attention was directed to the mineral water, when it was found that the most remarkable water of the county had been discovered. While the strongest natural springs of the county contain from 600 to 800 grains of mineral matter per gallon, this water contained over 1,200 grains. It is so concentrated that it will actually bear dilution with an equal volume of Croton water, which is more than one can say of our city milk, though the experiment is often made by the milkmen.

Like the enterprise of sending warming-pans to Cuba, this venture turned out an unexpected success. The well is now known as the "Ballston Artesian Lithia Spring." Soon after, the "Franklin" and "Conde-Dentonian" wells were bored at Ballston, and more recently the "Geyser Spouting Well" at Saratoga. All these have been successful in bringing up very concentrated waters of the same chemical character as the natural springs. It is probable, therefore, that water can be obtained anywhere in the southern portions of the county by tapping the underlying Potsdam sandstone. In all of these wells the water rises to and above the surface. Down in the rocky reservoir the water is charged with gases under great pressure. As the water is forced to the surface, the pressure diminishes, and a portion of gas escapes with effervescence. The wells deliver, therefore, enormous volumes of gas with the water, a perfect suds of water, carbonic acid, and carburetted hydrogen.

I will tell you about the High Rock Spring, the greatest natural curiosity of the county.

The High Rock Spring was the first to attract attention. It was well known to the Indians, who highly prized the medicinal virtues of its waters. The Indian name, Saraghtoga, means *place of salt*. In 1767 they brought Sir William Johnson to the spring on a litter. The spring rises in a littl mound of stone, three or four feet high, which a pears like a miniature volcano, except that sparklin water instead of melted lava flows from its little cr ter. When Sir William Johnson visited the sprin and in fact until quite recently, the water did n overflow the mound, but came to within a few inch of the summit, some other hidden outlet permittin it to escape. The Indians had a tradition, howeve which was undoubtedly true, that the water fo merly flowed over the rim of the opening.

A few years ago the property changed hands, an the new owners, convinced that by stopping the la eral outlet they could cause the water again to issu from the mouth of the rock, employed a number men to undermine the mound, and with a powerf hoisting derrick to lift it off and set it one side, tha the spring might be explored.

Just below the mound were found four logs, tw of which rested upon the other two at right angle forming a curb. I hold in my hand a piece of on of them. Under the logs were bundles of twig resting upon the dark brown or black soil of a pr vious swamp. Evidently some ancient seekers afte health had found the spring in the swamp, and t make it more convenient to secure the water ha piled brush around it, and then laid down the log as a curb. But you inquire, How came the roc which weighed several tons, above the logs? Th rock was formed by the water. It is composed tufa, carbonate of lime, and was formed in the sam manner as the stalactites and stalagmites I describe were formed. As the water flowed over the log the evaporation of a portion of the carbonic aci caused the separation of an equivalent quantity insoluble carbonate of lime which, layer by laye built up the mound. I hold in my hand a larg fragment of the rock; it contains leaves, twigs, ha zel nuts, and snail shells, which, falling from time t time upon it, were incrusted and finally imprisone in the stony mass.

ANALYSIS OF A FRAGMENT OF THE HIGH ROCK.

Carbonate of lime	95.1
Carbonate of magnesia	2.4
Sesquioxide of iron	0.0
Alumina	0.2
Sand and clay	0.0
Organic matter	1.1
Moisture	0.3
Undermined	0.4
	100.0

Below the rocks the workmen followed the sprin through four feet of tufa and muck. Then the came to a layer of solid tufa two feet thick, then on foot of muck, in which they found another log. Be low this were three feet of tufa; and there, seven teen feet below the apex of the mound they foun the embers and charcoal of an ancient fire. B whom and when could the fire have been built The Indian tradition went back only to the tim when the water overflowed the rock; how man centuries may have elapsed since even the logs wer placed in position? A grave philosopher of th famous watering place, remembering that botanist determine the age of trees by counting the rings on the section of the stem, and noticing the layers in the tufa rock, polished a portion of the surface, and counted eighty-one layers to the inch. He forthwith made the following calculation: —

High Rock, 4 feet, 81 lines to the inch	3,840 years.
Muck and tufa, 7 feet, low estimate at	400 "
Tufa, 2 feet, 25 lines to the inch	600 "
Muck, 1 foot	130 "
Tufa, 3 feet	900 "
Time since the fire was built	5,870 years.

As I have seen half an inch of tufa formed in two years on a brick which received the overflow from a spout of water containing only twenty grains of carbonate of lime in a gallon, I am inclined to think our antiquarian's estimates are not entirely reliable.

BRIEF NOTES ON SCIENTIFIC TOPICS.

A Novelty in Archæological Discovery. — In England, the discovery of skeletons by workmen engaged in making excavations is a matter of most daily occurrence, and excites only momentary tention. A skeleton belonging to past ages has, owever, been unearthed in Scotland which is somehat of a curiosity, inasmuch as it has clothes on. laborer was engaged in trenching at Racks, about e miles from Dumfries, when he came upon what rned out to be the remains of a man. Darkness ming on, further investigation was deferred until e next morning, when there was found the trunk a man's body, with the bones and clothing in a markable state of preservation, lying about nine ches below the surface. The coating of peat had en previously removed, so that originally the reains were embedded much deeper in the moss. he skeleton was headless; the garment in which was clothed was of a coarse woolen texture, and e boots were of the most primitive description, sembling specimens displayed in the Antiquarian useum in Edinburgh, each boot being one piece leather, awkwardly drawn into the shape of the ot by stitching up the back and front, and tied ith strong pieces of the same material. The *Pall 'all Gazette*, commenting on this discovery says: It is to be hoped that posterity will be spared the ain of discovering in a similar manner some of the othing worn by the present day. Our character r common-sense will be entirely lost if, for instance, pair of those high-heeled boots, such as some dies now wear, evidently with excruciating agony, e dug up ages hence, and exhibited as specimens clothing in the nineteenth century."

New Mode of Preparing Sulphuretted ydrogen. — This gas, which is so important a agent in chemical operations, may be conveniently nerated by heating a mixture of equal parts of lphur and paraffine (or with a larger proportion of lphur) in a flask to a temperature not much above e melting point of the sulphur; sulphuretted hyogen will be evolved with great steadiness. The thor recommends the process as the most convent of any yet devised for laboratory use. Where pound of the material is used in a suitable genering vessel, the evolution of gas may be prolonged several days with great regularity. The proiction of the reagent can be stopped and renewed pleasure by withdrawing or applying the lamp.

The Wear and the Repair of the Brain. The notion that those who work only with their ains need less food than those who labor with eir hands has been the cause of untold mischief. udents and literary men have often been the vicns of a slow starvation, from their ignorance of e fact that mental labor causes greater waste of sue than muscular. According to careful estiates, three hours of hard study wear out the body ore than a whole day of hard work at the anvil or the farm. "Without phosphorus, no thought," a German saying; and the consumption of that sential ingredient of the brain increases in proporn to the amount of labor which the organ is reired to perform. This wear and tear of the brain e easily measured by careful examination of the lts in the liquid excretions. The importance of e brain as a working organ is shown by the nount of blood it receives, which is proportionally eater than that of any other part of the body. ne fifth of the blood goes to the brain, though its erage weight is only one fortieth of the weight of e body. This fact alone would be sufficient to ove that brain-workers need more food and better od than mechanics and farm laborers.

The Nature of Alloys. — It has been prosed in England to call alloys "chemical mixtures." at they cannot be called mechanical mixtures, e fact that only the forces at the command of the chemist can separate them into their constituents proves. By no merely mechanical means could alcohol be separated from water or the zinc from brass; heat would, in both cases, play the principal part — and this force belongs to the domain of chemistry. As some metals will mix in any proportions, but still partially retain the character of chemical compounds, no objection can be made to the new definition. The term seems a fit one to rank between "chemical compounds" and "mechanical mixtures."

A New Application of Electricity. — It would be rash to say in these times what may or may not be accomplished by means of electricity. We can hardly be surprised at any triumph the versatile agency may achieve in new and unexpected fields. We cannot, however, help being a little astonished at the novelty of one of its recent applications. Dr. Bernier, a French physician, has proved it to be an efficient remedy for the evil effects of excessive drinking on the human nose. The doctor maintains that by application of an electric current to noses even of the most Bacchic hue, the flesh may be made "to come again as the flesh of a little child," and supports his assertion by a case performed on a female patient of his own, a woman of high rank. "Knights of the burning lamp," who have still some regard for personal appearance, will appreciate Dr. Bernier's discovery, as it promises them immunity from the dreaded outward testimony to their pet vice. We fear that the temperance reformers will consider the discovery as an unfortunate one, since its tendency may be to encourage habits of secret intemperance.

Sunflowers as Disinfectants. — More than a year ago we referred to the sanitary advantages of the cultivation of the sunflower in malarious districts. The subject has since attracted considerable attention abroad, and we see it stated that the British Government has addressed an inquiry on the subject to the Dutch colonial authorities, the answer to which has not yet been received. The *Militar Wochenblatt* has published an article by Dr. Valentine, of Frankfort, who gives many facts to show that the sunflower has the property of purifying air laden with marsh miasm, absorbing a great quantity of moist and noxious gases, and exhaling an ozonized oxygen. The plant, it is said, has proved itself particularly useful in this respect in the neighborhoods of Washington and Philadelphia, where its cultivation has rendered whole quarters healthy and fever-free, which had previously been rendered uninhabitable by the prevalence of fever. A Dutchman, Von Alstein, whose property was situated on some flooded land on the bank of the Scheldt, has planted three or four plots, thirty or forty yards from his house, with the effect of so much improving the air that for ten years no one on his property had been attacked with miasmatic fever, which continued to prevail on neighboring properties, where similar precautions were not taken. Besides this, as the French Sanitary Commission lately pointed out, the sunflower is a most useful plant. It yields about 40 per cent. of good oil, the leaves furnish an excellent fodder, and the stem, being rich in saltpetre and potash, makes a good fuel.

Popular Natural History in the Last Century. — A writer in *Land and Water*, in contrasting the past with the present, remarks that the study of natural history has increased to an extraordinary extent since the days of Bewick. Previous to that time the ignorance on the subject was often very entertaining. In the old version of the Psalms, by Sternhold and Hopkins (1787), we find, in Psalm ciii., —

"That filled with goodness thy desire,
And did thy youth prolong;
Like as the eagle casts her bill,
Again becoming young."

The authors probably believed that the young eagles were produced in this manner. In Holland's translation of "Pliny's Natural History," we read of eagles — "They die not for age, nor vpon any sicknesse, but of very famine, by reason that the vpper beake of their bil is so far ouergrown that they are not able to open it and feed themselves."

SATURN'S RINGS.

The rings of Saturn, formerly supposed to be solid and continuous, are now regarded as consisting of an indefinite number of extremely small satellites. They are, in short, a compact cluster of secondary asteroids, analogous to the primary zone between Mars and Jupiter. In the latter, it is true, a large proportion of the primitive matter has collected in distinct, planetary masses; while a similar result has been prevented in the Saturnian rings by their proximity to the central body. In one respect, however, we observe a striking correspondence. It has been shown that several positions occur in the asteroid zone where planetary periods would have simple relations of commensurability with the period of Jupiter, and that portions of the original ring occupying these positions would be liable to great disturbance. Now, the ring of Saturn is evidently subject to like perturbation by the nearest satellites. Hence gaps or chasms, analogous to those in the zone of asteroids, ought also to be found in the secondary ring. It has accordingly been noticed that Cassini's, or rather Ball's division occurs precisely where the periods of satellites would be commensurable with those of the four members of the system immediately exterior.

But astronomers have sometimes seen the ring of Saturn apparently separated by several black lines into concentric annuli. At other times, however, no such division could be detected. The fact, therefore, of the permanence of these gaps is extremely doubtful, except in the case of a division of the exterior bright ring. This has been frequently seen by eminent astronomers; and it is probable, though not absolutely certain, that it is never entirely closed. Most observers agree in placing it outside of the middle of the exterior ring. — *Prof. Kirkwood.*

HINTS FOR FRUGAL HOUSEWIVES.

To Preserve Bread a Long Time. — Cut the bread into thick slices, and bake it in an oven, so as to render it perfectly dry. In this condition it will keep good for any length of time required. It must, however, be carefully kept from pressure; otherwise, owing to its brittleness, it will soon fall to pieces. When required for use, dip the bread for an instant into warm water, and then hold it before the fire till dry; then butter it, and it will taste like toast. This is a useful way of preserving bread for voyages, and also any bread that may be too stale to be eaten in the usual way.

Fried Bread. — Put into a common biscuit pan a heaping teaspoonful of butter, and let it melt and spread over the pan; then take enough slices of bread (stale answers as well as any) to cover the bottom of the pan, and make a mixture to dip them in by beating well two eggs, and pouring in milk enough to soak the bread, seasoning it with a little pepper and salt; make the bread quite moist; then lay it on the butter and fry brown one side, and if too soft to turn, put it into the oven to brown on the top.

A Good Pudding. — The following recipe is specially commended by that excellent paper, the *Germantown Telegraph*, of Philadelphia: Pare and core half a dozen easily cooked apples, chop them into small bits; dry some bread in the oven — stale is the best — until it is crisp, then roll it into crumbs; butter a deep dish and place in it a layer of crumbs; then put in the apples, with a little

sugar, and such spices as you like; cover the apples with another layer of crumbs, and so on, adding a little beef suet, chopped as finely as possible; pour in half a pint of milk; bake till nicely browned, and serve with hard sauce.

Cracked Wheat. — For a pint of the cracked grain, have two quarts of water boiling in a smooth iron pot, over a quick fire; stir in the wheat slowly; boil fast, and stir constantly for the first half hour of cooking, or until it begins to thicken and "pop up;" then lift from the quick fire, and place the pot where the wheat will cook slowly for an hour longer. Keep it covered closely, stir now and then, and be careful not to let it burn at the bottom.

Wheat cooked thus is much sweeter and richer than when left to soak and simmer for hours, as many think necessary. White wheat cooks the easiest. When ready to dish out, have your moulds moistened with cold water, cover lightly, and set in a cool place. Eat warm or cold, with milk and sugar.

Potato Puffs. — The following is from a late English journal: "Take cold roast meat — beef or mutton, or veal and ham together — clear from gristle, cut small, and season with pepper and salt and cut pickles (if liked); boil and mash some potatoes, make them into a paste with an egg, and roll out, dredging with flour. Cut round with a saucer, put some of the seasoned meat on one half, and fold it over like a puff; pinch or nick it neatly round, and fry it a light brown. This is a good way to cook meat which has been dressed before.

Economy in Housekeeping. — The *Pall Mall Gazette*, commenting upon the Report of the Coal Commission, makes the following very sensible remarks: "The renewed apprehensions of an exhaustion of coal will possibly have the good effect of hastening certain reforms in our domestic arrangements which will economize not only coal but also other articles of consumption, and diminish the difficulties of housekeeping. One kitchen fire might do the work of a dozen by a well-arranged system of table-d'hôtes; this would reduce not only the coal merchant's but also the butcher's, the grocer's, the greengrocer's, and the baker's bills, and enable several families to have their dinners well cooked by one servant instead of ill cooked by many. The waste which takes place owing to the want of organization in our social and domestic arrangements is beyond belief; indeed it is not too much to say that, if the commissariat arrangements of a village full of agricultural laborers and their families were properly conducted on a system such as that pursued in a workhouse or convict prison, each bread earner in that village would receive a benefit equivalent to at least the doubling of his yearly income, and would, moreover, learn the meaning of the word comfort, which is not at present to be found in his vocabulary. Dwellers in cities would equally profit by learning the truth that waste and discomfort go together. If districts were to coöperate or establish stores, and make contracts for the supply of articles that are required in large quantities, they might obtain the same advantages as those possessed by regiments of soldiers and other organized bodies of men; but this would involve a system of order at home as well as at the store. So many ounces of bread, so much meat "without bone," are necessary in the course of the day for each member of a household — all beyond this is sheer waste. But few have studied housekeeping as a science, and the generality of people are as ignorant on the subject of quantity as on that of quality. Their only idea of food is some mass of provisions that will take away the appetite."

The soil of India produces no less than seventy-seven different kinds of rice.

The Arts.

A NOVEL WAY OF CUTTING GLASS.

Modern invention is remarkable for the novelty of the methods by which it accomplishes its ends. Its devices often surprise us by the utilization of some instrumentality which is the very last one that would have occurred to us as suited to the purpose. If it had been described to us as the wild dream of a madman whose insanity took an inventive turn, or as an ingenious burlesque of some of the singular "Yankee notions" that are sent to the patent office, we might be amused at it; but we can hardly believe in it as a sober reality. Many illustrations might be given of these "surprises" in the field of invention; but among recent instances of the kind we know of none more striking than what is known as "Tilghman's sand-blast," or the application of a jet of sand, driven by pressure, for the purpose of cutting or abrading glass and other hard surfaces. We are aware that sand *cuts* when it is driven against our faces by a violent wind, and geologists have called attention to the wearing away or furrowing of rocks in narrow mountain passes by long continued action of a similar kind; but we should never have anticipated that flying particles of sand could be made to do their work with perfect regularity, and that even the most delicate effects of engraving could be produced by such an agency. But all this, and more than all this, is achieved by Mr. Tilghman's machine, which consists essentially of a hopper, into which sand is fed in a dry state, and passes thence into a flexible tube, terminating in a smaller tube of metal, which passes through a larger tube or chamber, where the supply of air or steam is admitted. The sand, as it leaves the inner tube, is met by the air or steam blast, and is thus driven from the nozzle. The sand and blast tubes being flexible, they can be moved so as to apply the cutting to a considerable surface. An air pressure of seventy-five pounds to the square inch is sometimes used, but a blast of sand sufficient for many purposes may be driven by an ordinary fan wheel. A small quantity of sand is drawn into the current of air at the centre of the fan, and driven with great rapidity from the nozzle upon the surface to be cut or frosted, the latter being fixed to a table which is slowly moved before the machine. In a few seconds the smooth surface of a plate of glass is entirely effaced, and a beautiful frosted appearance is imparted to it. The sand, after it has been driven upon the surface, is conveyed again to the fan, and is thus kept in constant circulation.

The invention may be used for frosting, engraving, and grinding the surface of glass; cleaning and frosting of silver and other metals; cutting and lettering stone; embossing and engraving wood; and many other processes in the arts. Some of the effects of the sandblast are no less curious than they are wonderful. If the surface upon which the sand impinges be partly covered with a thin india-rubber cloth, paper, muslin, or even a coat of paint, the covered portions will be protected from the cutting action, their elasticity causing the grains of sand to rebound. By covering the surface with designs cut in these materials, beautiful etchings and engravings on glass and other hard substances may be obtained. In this manner perfect *fac-similes* of the finest lace may be transferred to glass without the slightest injury being done to the fabric of the lace. Even delicate leaves will resist the action of the sand-blast long enough to permit their outlines to be engraved on glass.

By increasing the pressure of the blast the hardest substances may be cut through. With a jet of three hundred pounds pressure, even corundum one and a half inches thick was pierced in twenty-five minutes with a hole an inch and a half in diameter. Iron and steel are cut away with the utmost facility. Marble may be lettered and carved in relief; wooden type may be cut; and it is even proposed to utilize the invention in coal mining to cut the mineral from its native bed. Altogether, the novel character and great utility of this invention give it an important place in the arts; and though its uses now seem to be extensive, yet there is no doubt that it will eventually be employed in many departments of industry where it has not yet been tested.

A NEW BLEACHING PROCESS.

An improved method of bleaching has been introduced by M. Pubetz, of Prague. He first prepares a vat in which 4 kilogrammes of permanganate of potassa or soda (soda generally being lower in price) have been dissolved, and adds to this $1\frac{1}{3}$ kilos. of sulphate of magnesia dissolved in water. The color of the liquid is then a very fine violet. These are the relative proportions for each 100 kilos. of wool, flax, or cotton goods to be bleached. A sulphurous acid bath is also prepared, containing 30 volumes of the gas to each volume of water. This bath must be heated to 25° C. when it is used.

The thoroughly cleansed materials to be bleached are first kept in the permanganate bath for a quarter of an hour, on being withdrawn from which they are found to be covered with a deposit of peroxide of manganese, the bath at the same time losing its beautiful hue. They are then plunged in the sulphurous acid bath, which reduces the peroxide of manganese to the state of protoxide, the salts of which, being very soluble in water, are readily removed by subsequent washing. If the yarns or fabrics resist the bleaching process, they should be treated with dilute hydrochloric acid, containing 1 part commercial acid to 20 parts of water.

This process of bleaching by alkaline permanganates deserves attention, and particularly because it affords a means by which even indigo may be discharged by a series of successive bleachings, leaving the stuff fit for re-dyeing.

NEW THINGS IN THE ARTS.

Black-Brown Varnish for Metallic Bodies. — The lustrous coat of black with which earthenware becomes coated, when long exposed to the action of hot coal smoke, is well known. Mr. C. Ruscher has conceived the idea of utilizing the property of the empyreumatic oils from coal, for the purpose of coating small articles of iron and steel, such as hooks and eyes, buttons, etc. For this purpose the metallic objects are placed upon an iron grating, over a layer of coal dust about half an inch thick, in a cylindrical vessel 18 inches high. The vessel is then securely closed, and being placed upon a bright fire, the bottom is brought to a red heat for about a quarter of an hour; it is then taken from the fire, and allowed to cool before it is opened. On the removal of the lid, the articles will be found to be covered with a tough, durable varnish, which does not crack with bending, and will resist a considerable elevation of temperature. The smaller objects may be rotated over a fire, in a machine like a coffee roaster, with a small quantity of coal

dust, by which the same kind of lustrous black coating is given.

Engraving on Glass. — A new mode of accomplishing this has been invented in Europe. Words and designs are printed on glass, by the use of type made of any suitable elastic material. The printing ink contains fluoride of calcium incorporated with it, and when the glass which has been thus printed on is submitted to the action of hot sulphuric acid, sulphate of lime is formed, and hydrofluoric acid set free, which immediately attacks the glass in the place of its birth. On subsequently washing off the ink stains, the design is found to have been beautifully etched upon the plate.

A Unique Device for Closing Beehives at Night. — A Missouri genius has recently taken out a very novel patent. The invention consists in so combining and arranging a poultry roost with the gates of one or more beehives, that the perching of the poultry upon the roost will serve automatically to close the hives. The object is to ensure the closing of the hives at night, so as to exclude the bee moth, and the opening of the same in the morning to permit the passage of the bees in and out during the day.

We wonder if the parents of this inventor did not emigrate from Connecticut, or some other portion of the original domain of Yankee ingenuity.

Lubrication of Steam Engines. — It has been a long time the practice with horologists to use graphite as a reducer of friction, in even the most delicate pieces of mechanism. In blowing engines also, if the gearing is copper, graphite is the only lubrication used. These facts led M. Thoma, of Memmingen, to try a mixture of graphite (prepared by decantation) and hog's lard, first in the stuffing box of a pumping engine, and subsequently upon a steam engine. The result was very satisfactory; the only care requisite was to keep up the quantity of graphite in the mixture, as otherwise it becomes too fluid. The next experiment was made with a paste of graphite and water. The result was equally good; the slight escape of steam into the stuffing box was sufficient to keep the graphite moist, and the lubrication seemed quite perfect, although there was no fatty matter present.

Filtering Alcohol. — The following method of filtering alcohol, or its solutions, is said to be very satisfactory, and is used extensively in Northern Germany. Clean, unsized paper (Swedish filtering paper is the best), is to be torn into shreds and stirred into the liquid to be clarified. The whole is then to be strained through a flannel bag, when the resulting liquid will be found to possess the utmost clearness and limpidity. A filter may also be made by spreading thin paper-pulp evenly upon stretched flannel or woolen cloth. When dry, the cloth so coated will be found to give better results than the felts, etc., commonly employed as filters.

PRACTICAL RECIPES.

Cement to resist Sulphuric Acid. — Take caoutchouc; melt this by a gentle heat, add from 6 to 8 per cent. of the weight of tallow, taking care to keep the mass well stirred; add dry slaked lime, so as to make the fluid mass the consistency of soft paste; and, lastly, add 20 per cent. of red lead, whereby the mass, which otherwise remains soft, becomes hard and dry. This cement resists boiling sulphuric acid. A solution of caoutchouc, in twice its weight of raw linseed oil, aided by heating, and the addition thereto of an equal weight of pipe-clay, yields a plastic mass which also resists most acids.

Green and Blue Fires without Sulphur. — In our last we gave some recipes for red fires in which no sulphur is used, and which are therefore to be preferred to the ordinary formulæ, especially for in-door experiments. The following recipes for green and blue fires have the same advantage: —

Green fire: 9 parts nitrate of baryta,
3 " shellac,
$1\frac{1}{2}$ " chlorate of potash.
Blue fire: 8 parts ammonic sulphate of copper,
6 " chlorate of potash,
1 " shellac.

The shellac must not be powdered, but only bruised into small fragments.

Glue for Card-Board. — For uniting card-board, paper, and small articles of fancy-work, the best glue, dissolved with about one third its weight of coarse brown sugar in the smallest quantity of boiling water, is very good. When this is in a liquid state it may be dropped in a thin cake upon a plate and allowed to dry. When required for use, one end of the cake may be moistened by the mouth and rubbed on the substances to be joined.

Cleaning Polished Brass. — First, remove all grease, which may be done with a solution of concentrated lye, and fine pumice or rotten-stone. A weak solution of muriatic acid and clean scouring dust will then brighten it, after which it may be oiled, with olive or cocoa-nut oil. Vinegar and common salt may be used instead of the acid. Weak vegetable acids are preferable on fine work, and vegetable oils better than animal fats.

Another method, which a correspondent of the *Scientific American* says will clean the dirtiest brass quicker and better than anything else, is as follows: Take eight parts water, and one part muriatic acid; mix them, and put in common water lime, until the mixture is thicker than water. Shake up well before using. Pour some on a rag, and put on the brass. Let it stay a minute or two and then rub.

Agriculture.

FARM PENCILLINGS AT LAKESIDE.

COST OF MILK.

Of the herd of cows at the farm, twelve are in milk the present winter, and wishing to ascertain the exact cost of the lacteal products at present prices of hay and grain, we instituted a series of experiments which extended over a sufficient length of time, and were conducted with the necessary care to settle the question. We find that the twelve cows consume in 24 hours 212 lbs. of good upland hay, 60 lbs. of corn meal, and 40 lbs. of fine feed. They drink 120 gallons of water, which is 10 gallons to each cow. The cash value, at the barn, of the hay consumed ($30.00 the ton) is $3.18, and the meal and feed cost $2.05. The aggregate cost of the food consumed each day is therefore $5.23. The total quantity of milk obtained, averaging the products of twelve days, is 96 quarts per day. The price of milk to milkmen, at the barn, is 5 cents per quart, which gives the aggregate value of the products in cash $4.80. This proves that the cash value of the food consumed by the herd of cows exceeds the cash value of the products by 43 cents each day, or in other words, the actual loss is 43 cents a day, not estimating the expense of taking care of the animals, milking, and other expenses incident to a herd of cows.

It shows that milk cannot be made, under the conditions existing at the farm, at less than 6 cents per quart, and in this estimate we assume that the manure pays for the care of the animals, risk, deterioration, etc. Now the question arises, Are the conditions under which milk is produced from this herd favorable or unfavorable? Is the food larger in amount, or more costly, or is the yield of milk less, than that of others in Massachusetts? We think not. It is probable that but very little of the pure milk sold in this city gives to the producer any profit; indeed, it is quite certain its production is attended with positive loss. There are but few towns in the State, or in New England, where the best hay is worth less than $30.00 the ton, and grain is not less in price than our estimate. We think also that there are but few herds of cows which in the dead of winter will average more than 8 quarts per day each; as a rule, the average is less. It is evident there is nothing very "gorgeous," as Ik Marvel would say, in the business of manufacturing milk. We suppose milk is sold by farmers to market men at less than 5 cents per quart, in many parts of the State; and when this is the case the loss is a serious one. In a few of the warm months of the year, when the pastures are in good condition, and the flow of milk copious, the cost of milk is not felt, but a mistake is made in assuming that it costs *nothing*. The feed of pastures even in remote sections has a *value*, and having regard to that value, the labor of taking care of cows, and the risks and losses incident to maintaining a herd, milk cannot be made for much less than five cents a quart even in the summer time. The farmer must have a higher price for his milk; common justice and fair dealing demand it, and every right-minded consumer doubtless is willing to pay for an article at least what it costs. The producer has the staff in his own hands. If his customers refuse to give a fair price for the article, let him imitate one of the bad practices sometimes seen in his cows, — let him "hold up" on the milk. A "milk famine," to be sure, would not be quite as bad as a water famine in a large city, but it would be decidedly inconvenient, and would serve to show the importance of the article, and the necessity of encouraging its production.

ABOUT COWS.

"What breed or kind of cows do you prefer?" asked a friend who was contemplating the stocking of a farm just purchased. "Well," we replied, "for our work, we prefer the good old-fashioned domestic cow, a cow purely 'native,' such as have been in New England for two hundred years." "But what do you mean? do you not admit the great superiority of the Jerseys, the Alderneys, the Devons, the Short Horns, the Dutch, the Kerry, the" — "No sir," interrupting him, "we do not admit that for stocking a New England farm, for real practical work, there is any cow so useful, so profitable, as a carefully bred, well-taken-care-of domestic cow." If one has a fine lawn, or a fancy farm, which he desires to ornament with attractive animals, put in some of the beautiful Alderneys or Jerseys; or if he has broad, rich pastures, such as are common in Holland, a few of the large, black Dutch animals will do very well, and be pleasing to the landscape, but none of these will flourish on our brown hills, and under ordinary farm treatment. We have in our herd a few of the finest, pure-blood Jerseys, and some grades of the different breeds, and they are our pets. The Jerseys are so docile, intelligent, and beautiful, they become great favorites wherever kept; and if a family desires a single cow, to receive extra care and feeding, they are indeed desirable. In our climate the winters are long and severe, the summer feed scanty, and no foreign breeds of cows will do as well, looking not alone to milk, but to beef, as

our common hardy cows. If we would take as much pains to improve our native breeds as is bestowed upon the imported, great good would result to our dairy farming. We have a cow, of pure, unadulterated native blood, which in September, soon after dropping her calf, gave *twenty quarts of good milk at one milking.* She is now giving fourteen quarts each day. If any of the fancy imported varieties do better than this, they have not come under our notice.

THE BUTTER QUESTION.

One thing is certain, if the statements of writers in our agricultural journals are reliable, the quality of milk, as regards the yield of butter, is very variable. Some observations made a few months ago in the JOURNAL, regarding the number of quarts of milk required to make a pound of butter, have created considerable excitement among milk producers, and the important question now is, Who has obtained a pound of butter from the least number of quarts of milk? So far as we have seen, no one reports success equal to that of the "Great American Butter Company," whose agent was in this city some months since, manufacturing the butter and selling "rights to make," etc., to the wondering crowd. It will be remembered that he claimed to make a pound of good butter from *a pint of milk.*

Mr. D. F. Appleton, of Ipswich, stated in the *Ploughman*, a short time since, that he was procuring a pound of butter from eight quarts of milk. This we regarded as an extraordinary result, even when we considered that Mr. Appleton's herd is composed of the choicest animals from the best breed of butter cows, and that their keeping is unexceptionable. But Mr. Call, of Windham, N. H., reports in the same journal that he procures a pound of butter from seven and a half quarts of milk, and his cow is fed on *meadow hay*, with a fair sprinkling of corn meal. This is a remarkable cow certainly. The more closely we examine the statement, the greater the wonder. Fifteen pints of milk, legal measure, weigh about 16 pounds, or 256 ounces avoirdupois. The very best milk we have ever analyzed contained 87 per cent. of water, and therefore if this milk was no better, 223 ounces of the 256 from which the butter was procured were simply *water.* It is safe to assume that the buttermilk left from Mr. Call's churnings does not have much nutritive value.

A QUESTION.

WOULD it not be more sensible, and conducive to the interests of honest husbandry, for the gentlemen who so freely certify to the extraordinary virtues, as a destroyer of insects upon plants, of an inert rock powder found in New Hampshire, to reflect before signing such documents, that any dusty substance, like plaster, ashes, lime, etc., will in a great measure protect vines and plants from the depredation of insects? We have used plaster many years for these purposes with satisfactory success, and so long as it can be bought for half a cent a pound, we shall not recommend our neighbors to purchase powdered dolomite, at three times that cost. Both act alike, and protect plants from insects, simply by their presence. They have no power of destroying insects, but by covering the leaves and the ground, the insects do not readily get at the plants. That is all. It is not necessary to pull the mountains of New Hampshire to pieces to obtain a dusty rock powder to put about our pumpkin and melon vines, and upon our onion beds. Fine road dust answers a good purpose, if neither plaster, lime, or ashes can be obtained.

We don't suppose these certifying gentlemen *pay anything* for the rock powder *they* use, but the evil consists in inducing unsuspecting and maybe indigent farmers to part with their money in purchasing such articles.

ANALYSIS OF FISH GUANO.

TWO specimens of fish pomace, or fish guano, made in Gloucester, Massachusetts, have been subjected to analysis during the past month, with the following results: —

No. 1.		No. 2.	
Water,	17.26	Water,	20.01
Ash,	10.43	Ash,	29.92
Organic matter,	72.31	Organic matter,	50.07
	100.00		100.00

No. 1.		No. 2.	
Contained nitrogen,	6.82	Contained nitrogen,	6.50
Phosphate of lime,	8.01	Phosphate of lime,	24.74

The amount of water may seem large, but it is difficult and expensive to carry desiccation to a higher point; and therefore it may be assumed that about twenty per cent. of water in the substance is an unavoidable quantity, and may serve as a standard in estimating its value. The amount of phosphatic and nitrogenous matter contained in these specimens proves that they are valuable manurial agents, and well adapted to all the grass and grain crops.

FARM PAPERS.

WE desire to say to farmers and gardeners who write to us at this season of the year, requesting copies of our papers relating to the manufacture and use of fertilizers, farm experiments, etc., that the book just published by Messrs. Hurd and Houghton, "FIRESIDE SCIENCE," contains them all. The titles of the essays are, "The Food of Plants," "Farm Experiments at Lakeside," "The Relations of Water to Agriculture," "Farm Pencillings at Lakeside," etc. These practical papers upon agricultural matters occupy nearly one third of the 300 pages which the volume contains. It may be found, we presume, at most bookstores throughout the country, or it may be ordered from Messrs. Hurd and Houghton, New York, direct. The price is $1.50. The publishers of the JOURNAL will send the book, as a gratuity, to any one who will send four dollars and the names of four *new* subscribers.

CORN AS AFFECTED BY CLIMATE AND SOIL.

MR. T. H. WEST, of Haverhill, Mass., writes us as follows, regarding Northern corn on Southern soil: —

In confirmation of Mr. Maxwell's experience in regard to raising Northern corn on Southern soil, I would say, that in the year 1835 I took some superior Northern seed corn, raised in Massachusetts, to the State of Mississippi, where I planted it.

The result was that it grew only about three feet high, and I am not sure that it had even "nubbins." It was an entire failure. It was planted on a rich limestone soil, where the common gourd-seed corn of the country would have grown nine feet in height, and produced large, well-developed ears. I think the failure of Northern corn, in that latitude, is due to the climate, although the soil differs very much from ours. There, the soil is a deep, heavy limestone, containing much humus and all the elements of fertility — especially on the river bottoms, or canebrake land, where I have seen a cornfield of a hundred acres, the corn entwined with the flower we call "morning glory" (convolvulus), and over the field the pumpkins lay so thick that a man could walk without stepping off a pumpkin. Upon such land it is inconceivable why Northern corn will not grow, unless it is on account of climate.

I think the climate will also be unfavorable to clover, on account of causing the soil to bake in time of drought (although the leguminous cow-pea grows luxuriantly), but it would be more likely to succeed on the pine-lands. In what was known as the switch-cane region, not far from Tuscaloosa, supposed to be the richest and best cotton land in the State, I should hardly suppose such soil would need the aid of green crops ploughed in. But in the more healthy and higher pine-land, whose fertility fails after about ten years' cultivation, I should suppose such a course judicious, as a means of renovation.

GOOD ADVICE FROM THE ANTIPODES.

OUR own country is not the only one where decreased production and wornout lands are beginning to admonish the farmer that Nature's laws cannot be transgressed with impunity. At a meeting of the Victoria Agricultural Society, at Heidelberg, Australia, Mr. Josiah Mitchell, of the Royal Park Farm, called attention to the fact that "the American system," as he termed it, by which "the settler subdues a piece of land, flogs it to death, and abandons the carcass, and then repeats the operation on a new subject," is prevalent among the British colonists there. Indeed, it would appear that some of them, having disposed of their first victim, are now attacking a second; for the farmers, from already exhausted districts of South Australia, are removing to Victoria, to take the benefit of a recent land bill, and of course to pursue the same ruinous system there. We make a few extracts from Mr. Mitchell's able address on "Rational Cultivation:" —

WHAT IS NOT RATIONAL CULTIVATION.

In the first place, then, the growth of the same crop year after year on the same land, "wheat after wheat" for instance; the production of successive grain crops without any manure, and with only an occasional bare fallow when the land becomes foul; burning straw instead of converting it into manure by the aid of stock, and restoring it again to the land; the laying down of land to grass after it has been exhausted by the growth of grain, — these are some of our practices that are not rational, because opposed to the laws of Nature, — rotation and restitution, — which govern the growth of plants and the continued fertility of the soil.

ROTATION OF CROPS.

Rotation, I have said, is a law of Nature that governs the growth of plants; it compels change of soil or situation. No plant will thrive continuously on the same spot. This applies as well to oak and pine forests as it does to wheat, oats, or any of our cultivated crops. The necessity for rotation or change of crop is caused partly by exhaustion in the soil of elements essential for the healthy growth of the plant, and partly in consequence of the excretory matter thrown off by the roots, rendering the soil unfit for its further growth. Yet one plant, by its death and decay from these causes, makes the most suitable preparation for the healthy growth of some other plant belonging to a different order. In

this way the great globe we inhabit has been converted out of barren rocks into the thing of beauty we now see it, and became fitted for the sustenance of man. It is upon this law, that the modern practice of British agriculture is founded, and no system of cultivation can be deemed rational if it does not embrace some rotation of crops. I need only instance the well-known success of wheat grown after peas, beans, or clover, to illustrate the advantages of rotation.

RESTITUTION OR COMPENSATION.

In conjunction with rotation we must also have restitution, or compensation, if we would maintain the fertility of the soil and avoid barrenness. Restitution and rotation should be the watchword, the creed, not merely as a matter of faith, but the everyday practice of all who desire to cultivate rationally. We cannot go on ploughing and sowing, reaping and mowing, taking all away, and giving nothing back to replace the mineral substances removed from the land. We cannot, I say, long continue this system of robbery, even with some sort of rotation, without being brought face to face in the long run with one of these two alternatives, restitution or barrenness. The time, of course, will vary with the quality of the soil, but the end must come. How little this inexorable law of restitution seems to be understood, or, if understood, how much we, by pursuing our present exhaustive practice, seem to disregard it! Yet it is no light matter, but one fraught with serious consequences to any community where a system of spoliation is carried on, instead of rational cultivation.

BEGINNING AT THE WRONG END.

In colonial agriculture generally the natural tendency seems to be to begin at the wrong end. Instead of starting from grass and the depasturing of stock, the production of grain is made the starting point. By the continued production of grain alone, the land becomes exhausted, and thereby unable to produce grass except of the most worthless and innutritious description. Now the rational course would be to start from grass as a basis, and in conjunction with this, through green crops, stock, and manure, advance to grain; then, in the course of any rotation, back again to grass. The laying down of cultivated land to grass, after a course of cropping, may be likened to putting it to bed; of course the more comfortable we make it the better it will rest, and consigning it for a time to "Nature's sweet restorer, balmy sleep," which, if I may be allowed a slight liberty with poetic diction, —

Swiftly on dewy pinion flies from fields
Of woe, too often cropped with golden grain,
And lights on slopes unruffled by a plough.

The bare fallow is like poking up the fire to make it burn away all the faster. But a green crop put in with plenty of good muck, and fed off on the land, is the true "roast beef of old England," and will be followed by plenty of bread, and cheese, and beer.

KINDNESS IN THE TREATMENT OF COWS. — Since referring to this subject in the JOURNAL we have seen in an exchange certain "rules for the cow stable," quoted from *The Scottish Farmer.* The fourth and fifth of these rules are as follows, and the owners of milch cows should see that they are invariably obeyed by their employees: —

"Gentle words and kind treatment are enjoined. Striking cows with stools, clubs, or heavy sticks will under no circumstances be allowed.

"In driving the cows to and from pasture, great pains must be taken not to hurry them."

A TEXAS paper reports that since last September 19,000 emigrants from Tennessee and Georgia, with 1,664 wagons, have entered the "Lone Star State," and that is but a part of the great tide-wave of population flowing to the Southwest.

Boston Journal of Chemistry.

WM. J. ROLFE, A. M., *Associate Editor.*

BOSTON, FEBRUARY 1, 1872.

ANALYSIS OF JOURNALS AND NEWSPAPERS.

WE suppose our publishing friends at home and abroad will pardon us for subjecting their journals to the action of fire and acids, so as we do not throw into the crucible the learned opinions, essays, and statements which they contain. Having been employed by a paper dealer to make chemical examination of two specimens of paper which were offered at the same price, results were reached which were somewhat surprising. One specimen gave only 0.68 per cent. of ash, while the other gave 9.61, and both in appearance were equally good. The ash of the first specimen was almost wholly composed of silica, tinged with a little oxide of iron, while the second was made up largely of *kaolin,* an aluminous earth, very fine and white. With each one hundred pounds of this paper there was incorporated $9\frac{1}{2}$ pounds of the clay, which cost the manufacturer about one cent a pound. If pure paper costs the manufacturer 10 cents a pound, the adulterated could be made at about 9 cents, which affords a fine margin for profit.

The results of this investigation led us to examine the paper used by various publishers whose journals come to us by way of exchange. We present below the names of some of these journals, and in connection give the ash determination of each. The percentage of ash is given as found after drying the paper at a temperature of 100° C.

Scientific American, New York	14.50
Artisan, Athens, Ga.	10.62
Independent, New York	8.71
Telegrapher, "	7.89
Nation, "	6.21
Tribune, "	3.23
Herald, "	3.06
Post, Boston	4.50
Advertiser, "	2.69
Herald, "	.98
Boston Journal of Chemistry	.46
Foreign Journals.	
Science Gossip, London	21.59
Chemical News, London	17.38
Academy, "	17.26
Land and Water, "	17.25
English Mechanic, "	15.32

From these determinations it will be seen that some of our journals are indeed "of the earth earthy." Among those examined from this country, our esteemed neighbors of the *Scientific American* send out weekly the heaviest freight of *terra alba.* Their paper-maker gives them 14 pounds of clay in each one hundred pounds of the paper; and if, as is probable, they use 3,000 pounds weekly, he sends them for distribution something over *eleven tons* annually.

We are disposed to claim that our transatlantic cousins fail to excel us in most industrial processes, but it must be conceded that the paper-makers across the big ferry are more expert than ours in fabricating paper from clay. That useful and entertaining journal, *Science Gossip,* gives in its paper *rather more than one ton of earth in every five,* and the others in the list follow close in the amount distributed.

The use of clay in paper may or may not be fraudulent; it depends upon the conditions under which it is sold. The papers containing large quantities of clay are apparently good, and probably satisfactory to publishers and patrons. If so, there is no fraud committed in using clay, provided the purchaser understands it, and the price corresponds with the price of the cheap material used in the manufacture. We wish good paper could be made *entirely* of clay: we could then double the size of the JOURNAL without increasing the expenses of publication. Our paper-maker, it will be seen by referring to the list, ignores the use of it altogether, the amount of ash being less than half of one per cent. There is a heavy, crisp quality observable in the English journals, which is somewhat disagreeable and inconvenient. It is probable that considerable tough vegetable fibre and peculiar sizing is necessary in paper which contains much clay. If journalists know regarding the materials used in fabricating their paper, they will be better able to fix upon just prices for the material, and hence the investigations here presented may be of some service to the craft.

WATER CONTAMINATED WITH SEWAGE.

No one could doubt the great importance to the health of families, of a proper disposal of town and house sewage, who had opportunities of becoming acquainted with the character of well and spring waters brought to chemists for examination. It is certain that waters are used in hundreds of families in the cities and towns of this country, which contain the germs of some of the most distressing and fatal diseases. Waters have been brought to us for chemical examination, during the past year, which were found to be loaded with impurities resulting from defective sewerage, and the cause of sickness in the families was unsuspected. We have for many years persistently urged this matter upon the attention of medical gentlemen, and we again place it before them. Our journal is read by more physicians, probably, than any other published in the country, and therefore we should fail in our duty if we did not endeavor to awaken the attention of this large army of men who do battle against disease, to the agencies which *cause* disease.

As regards private dwellings, the drainage is usually very imperfect. Among farmers, and others living in the country, all the waste waters and refuse matter are thrown out of kitchen windows, or a wooden spout leads from the sink through the walls of the house, and this affords a conduit for the filthy fluids to flow to the ground outside. Some dwellings have a loose stone drain which leads a short distance to a low place, and here the impure liquids accumulate, fermenting in summer, and spreading over the frozen ground in winter, seeking lower levels in which to repose. Now it often happens that wells are located in close proximity to these open or concealed cesspools, and into them the sewage flows. It is not safe to assume that a well is secure from contamination because it is situated a little higher than a drain or cesspool, or at a considerable distance; the character of some soils is such that it will allow the fluids to percolate through and reach the waters in the well even when they are many rods away. How disgusting the thought of using these filthy waters in families! They are usually clear enough, and often the taste is unaffected, but the organic *débris* and the soluble salts they contain are positive poisons. A physician when called to a case of typhoid fever, or any of the eruptive or the zymotic diseases, should immediately set himself to the work of *investigation*, with the view of discovering the *cause* of the affection. Nearly all acute and chronic affections originate from some specific poison which may or may not be removable, and in the search for the sources of physical maladies the sewerage of the house or neighborhood should receive special attention. The benefits which intelligent cultivated physicians confer upon families do not consist entirely in prescriptions for the sick, but in the sagacious care exercised over those who look to them for advice when medicines are not needed.

But it must be understood that the evils from bad drainage do not always concentrate in the waters used, but from the infectious germs originating in and arising from fermenting vegetable and animal substances connected with drains. Some high medical authorities in England estimate the number of deaths in that country resulting from miasmatic exhalations from sewage, and from contaminated water, as high as fifteen thousand annually. In this country, very many cases of typhoid fever originate from this cause, and numerous deaths occur, among the wealthy as well as among the poor. There can be no doubt that the recent severe illness of the Prince of Wales resulted from the use of water and air which had been poisoned by sewage matter. Our advice to all housekeepers is, to guard well all sources from whence may arise contaminations in water or air, and by so doing many very serious evils will be prevented.

IODINE.

THIS important agent has greatly advanced in price during the past year, and the prospect is that it will be exorbitantly high for a long time. The manufacture of the substance is largely carried on in the British Islands and in France, but it has never been successfully produced in this country. Several years ago a manufactory was established at Rockport in this State; but the price was so low that it could not be made in competition with the English product. It is manufactured from the common sea-weed found in such large quantities upon our coast, and we are inclined to think that a profitable industry might be established in its manufacture, since the price is so greatly enhanced. It is now used in the fabrication of a popular dye, and this will increase the demand beyond the capacity of supply abroad. Iodide of potassium, so popular as a therapeutic agent, is now so costly as to be almost beyond the reach of physicians, and the photographic artists suffer from the rise.

Although iodine is manufactured from *Fucus*, *Laminaria*, and other varieties of sea-weeds, it must be remembered that the plants get it from the waters of the ocean. That we may show to the reader how sparsely the element is contained in sea water, we will state that although the starch test for iodine is so delicate that one part dissolved in 300,000 parts of water is easily detected, yet if we concentrate sea water to the *one hundredth* of its original bulk, it affords no characteristic reaction. It is evident, therefore, that the proportion of iodine in sea water must be less than *one part in thirty millions of water*. It requires more than thirty million pounds of sea water to furnish the marine algæ with one pound of iodine, and yet one house in Glasgow, Scotland, manufactures *forty tons*, or eighty thousand pounds, of iodine from the weeds every year!

ANALYSIS OF WATER FROM AN ARTESIAN WELL.

WE have recently analyzed water taken from an artesian well in this city, which presents some interesting results. The boring was made to supply water to Messrs. Hallet & Davis's extensive Piano-forte Manufactory on the low ground in the southern section of the city, and was carried to the depth of ninety feet. The well is tubed with iron throughout its whole extent, and the water rises to the top of the tube. In proceeding downwards, the borer, after passing through the mud and drift, came upon a bed of clay ten feet in thickness; underneath this was a bed of metamorphic rock, then another clay bed; and finally the drill, after passing through a stratum of loose sand and gravel, struck upon slate rock, and at this point the boring was suspended.

Analysis of the water as obtained after pumping half an hour, gave the number of grains of solid matter in each gallon as 89.13, composed as follows:—

Silica	.40
Sulphate of lime	7.11
Carbonate of lime	3.15
Chloride of magnesium	9.43
Chloride of sodium	69.04
	89.13

The peculiarity of this water consists in the large amount of chloride of sodium, or common salt, found in it, and indicates that the well has some subterranean connection with the ocean. As the tubing is continuous and perfect, it cannot be at a point higher than the stratum in which the boring terminates. The clay beds would seem to be capable of keeping out any salt water in the vicinity, and therefore it is probable the communication is direct with the waters of the bay at some remote point. The rock which was reached, is undoubtedly the same as is now being perforated by the Boston Gas Co., who in their boring have gone down over 1,400 feet.

FALSE COLORS.

WE are not sure that "the age of adulteration" would not be the most appropriate appellation that could be selected to distinguish the period in which we live. With the progress of scientific discovery new facilities are developed for making things appear what they are not, and no small share of the inventive talent of the time is devoted to this dishonest end. There is scarcely an article in common use that is not liable to be adulterated or sophisticated. Even the medicines upon which we depend for the saving of our lives when attacked by dangerous diseases are often rendered either inert or positively mischievous by some villain who thinks more of a few cents' gain than of the risk of killing an indefinite number of sick people. The diabolical character of these "tricks of the trade," as they are mildly called, is well illustrated by some facts brought out at a late meeting of the Medical Society of London. One of the members stated that, being struck by the repeated failures that followed the use of some vaccine matter which he had purchased in tubes, he had examined it with the microscope, and found what appeared to be "buccal epithelium and starch granules." Independent evidence has been given to show that some venders of vaccine lymph manufacture the article from saliva and tartar emetic or croton oil. The man who would put such a preparation into the market deserves to be vaccinated with it himself, and then sent to board awhile in the nearest small-pox hospital.

This wide-spread adulteration naturally begets an equally wide-spread suspicion in regard to whatever is susceptible — and what is *not* susceptible? — of adulteration. Man, being often "taken in" by false appearances, naturally comes to distrust the evidence of his eyes, and wants to subject everything to some crucial test that shall show its true character beyond a doubt. Especially are we suspicious of what seems to be of extraordinary merit or peculiar excellence. Where the rose and the lily are blended with the most exquisite perfection on the feminine cheek, we are quick to surmise that art has been called in to supplement the work of nature. Even birds and beasts do not escape this scrutiny and criticism. We have our doubts as to the reality of their colors. For aught we know, the horse whose hue takes our eye may have been painted, and his beauty may not outlast the first drive on a rainy day. The bright plumage of a canary may awaken distrust, as in a case which we find reported in a late English paper. A Nottinghamshire man writes to the editor, complaining that three canary birds which he sent to a competitive exhibition at Derby were subjected to various tests, such as acids and alkalies, in consequence of the unnatural brightness and beauty of their color. Feathers were, he alleges, also plucked out of them, and he was requested to leave them for a month to see if the new feathers would be of the same hue as those of which they had been deprived. He declined this offer, and the birds were pronounced to be disqualified for the exhibition on the ground that their color was unnaturally beautiful. The much maligned birds subsequently each took a prize at a competitive canary exhibition held at Nottingham, though even there they were viewed with suspicion, owing to

ie extraordinary beauty of their color, and were gain subjected to certain chemical tests. When e consider the tricks played by ladies, horse-ealers, and bird-fanciers, we cannot be surrised that the drawing-room, the stables, and ie bird-cage all come in for their share of susicion; but how lamentable it is that the world hould be reduced to such a condition of doubt nd distrust that it cannot believe in the existnce of beauty without paint! Perhaps even ie green of the fields may some day be attribted to arsenic and agricultural vanity.

[Communicated to Boston Journal of Chemistry.]

N THE SEPARATION OF TIN, ANTIMONY, AND ARSENIC.

BY S. P. SHARPLES, S. B.

THIS is generally regarded as one of the most ifficult problems the chemist has to deal with. he method by fusion as given by Fresenius is diffiilt to the student, and gives in most cases very unitisfactory results. And the method given by Will no better. I have used the following, which ives rather better results than either of the above, nd is more readily performed by the student.

The metals are brought into the form of sulphides the usual manner. These, while still moist, are oiled with an excess of hydropotassic sulphite, hich dissolves the arsenic and leaves the tin and ntimony unacted upon. Add sulphuric acid to the olution to slight acid reaction, and boil until all the O_2 is driven off; then add bromine water in excess oxidize the arsenic; add ammonia to alkaline retion, and then ammonia magnesia mixture; allow it stand for some hours. Formation of white precipiite indicates arsenic; or the solution, after treatment ith sulphuric acid and boiling, may be tested with itrate of silver, or any of the other ordinary tests r arsenious acid.

The undissolved residue from the hydropotassic ılphite is washed thoroughly with hot water, and ien dissolved in sodic hydrate. If an undissolved sidue is left, this is examined for gold and platinum. romine water is then added in excess, and the sotion is boiled a few minutes; it is then allowed to ol, and mixed with its own volume of alcohol. The rmation of a white granular precipitate indicates itimony. Filter and test the precipitate by any of e ordinary methods for antimony. The filtrate is sted for tin by acidifying with sulphuric acid, and en adding hydrosulphuric acid water. The forration of a yellow precipitate which soon changes a dirty brown, indicates the presence of tin. Filter id test by the blow-pipe.

"FIRESIDE SCIENCE."

THE *Daily Advertiser* of this city thus kindly noes the volume: "*Fireside Science* is the title of beautiful and really useful volume from the press Hurd & Houghton. Many of the essays of which is composed have previously appeared in the OURNAL OF CHEMISTRY, and were there received ith a favor they entirely merit. While they are curate and wise in their presentation of scientific cts and principles, they are exceedingly simple, teresting, and popular in style, a combination of e entertaining and the instructive rarely achieved. me of the titles of essays will give a good idea the scope of the work, and we quote them: Chemistry of a Hen's Egg,' 'Rebreathed Air,' The Human Hair,' 'The Clothing we Wear,' 'The in and Bathing,' 'The Food of Plants,' 'The rigin and Nature of Springs,' 'Farm Experiments Lakeside,' etc. The housewife and the farmer ill each find here some useful information in their ecial departments, and everybody may get from valuable hints concerning the care of the body."

The *Boston Journal* remarks as follows: "*Fireside Science*, by J. R. Nichols, M. D., editor of the JOURNAL OF CHEMISTRY, is a volume of practical, readable, and entertaining essays of every-day life. Such matters as every one inquires about and few know, are written of here in a style clear and accurate. A glance over the table of contents is enough of itself to induce a desire for reading the book clear through. These essays, born of the fireside, commend themselves to it, and will find a congenial home around it."

The *Boston Post* says: "We have received Dr. Nichols's *Fireside Science*, published by Hurd & Houghton. It is a handsome volume, containing a number of popular scientific essays upon subjects connected with every-day life. Its style is charming, and the valuable information which it contains is conveyed in the pleasantest manner."

EDITORIAL NOTES.

THE SEARCH FOR DR. LIVINGSTONE. — At a meeting of the Royal Geographical Society, in December, Sir Henry Rawlinson stated that the council intended to address the Foreign Office, with a view of arranging, either directly from the Foreign Office, or through coöperation between the Foreign Office and the Society, some means of communicating with Dr. Livingstone, either by sending messengers into the interior of Africa, and offering a reward of 100 guineas to any African who will bring back a letter in Dr. Livingstone's handwriting to the sea-coast, or by organizing a direct expedition, headed by some experienced and well-qualified European, who should himself penetrate to the point where Dr. Livingstone is supposed to be. Mr. Rassam said his experience in Abyssinia convinced him that the best plan would be to send native messengers; but Captain Rigby, who for many years officially resided at Zanzibar, said it would be impossible to get a messenger into the interior and back. He thought the only means of communicating with the great traveller was by a small armed expedition under an experienced European. The president said that the council, feeling that the loss of 50 or 100 guineas would be nothing compared with the object to be gained, had thought it desirable that the plan of messengers should be tried first, and, if it failed, then the more serious expedition might be resorted to.

THE PREVENTION OF CONFLAGRATIONS IN CITIES. — The Chicago fire and its lessons are still the subject of much discussion in Europe as well as in this country. The London journals are raising the question whether that city could be devastated by a conflagration more extensive than the famous "Great Fire" of 1666, and it would appear that, in spite of the solid and substantial character of English architecture, the business quarters of the metropolis are exposed to some very serious risks. Immense stocks of inflammable goods are piled up in warehouses, in the basements of which boxes and packing cases are made by gaslight. The walls between the buildings are often cut through in order to make room for the expansion of a heavy business; and every building is crowded to its utmost capacity, on account of the concentration of such an enormous trade in so limited a space. There have been destructive fires in that part of London, and a far worse one is at least a possibility.

In Paris there is less risk of a great fire, and in many Continental cities such a catastrophe could not occur under any conceivable circumstances. With regard to Florence, for instance, Hiram Powers writes as follows: "Although there have been frequent fires in the city during the thirty-four years of my residence in it, not one house has been consumed, except a theatre, and that was not entirely destroyed. Rooms full of goods have been heated like ovens by ignited calicoes, straw hats, etc., but as the floors above and below were all covered by thin brick tiles, the goods burned without ventilation; and as there was no flame, a smell like that of a coal pit soon gave the alarm, and the fire was soon extinguished by no other engine than a squirt holding about a gallon, which discharged a well-directed stream through some aperture. The secret of fire-proof building, then, is this: It must be made impossible for the flames to pass through the floors or up the stairway. If you will have wood floors and stairs, lay a flooring of the thinnest sheet iron over the joists, and your wood upon that; and sheathe the stairs with the same material. A floor will not burn without a supply of air under it."

ARTIFICIAL MILK. — We have elsewhere suggested that it may not pay for the farmer to send milk to market at the present price of the fluid. If the supply should actually be withdrawn, we may be driven to the use of a substitute, as was the case in Paris during the siege. M. Dubrunfaut at that time devised an artificial milk, made by dissolving $1\frac{1}{2}$ ounces of sugar in a quart of water, adding an ounce of dry albumen (from white of eggs) and 15 to 30 grains of soda crystals, and then making an emulsion of it with from $1\frac{1}{2}$ to 2 ounces of olive oil. As the war progressed, gelatine was substituted for the albumen, and then slaughter-house fats, — purified by melting at 150° and then projecting into them small quantities of water, — for the olive-oil. One firm made in this latter way, 132,000 gallons of milk daily for Paris consumption.

ATOMS.

ANOTHER new chemical nomenclature has been proposed in England, by Mr. Metcalfe Johnson, who would fain call nitric acid by the euphonious appellation of *nitrodoxohydroxon* and bisulphate of soda by that of *natrodoxobisulfotroxon*. — A medical journal warns the public against the green kid gloves now much worn, as many of them are dyed with an arsenic color which produces on the hands an eruption very difficult to cure. — In reply to the assertion that "one half the number of professional aeronauts have been killed in the exercise of their vocation," Mr. Coxwell, who is himself a "balloonist," says, that in the thirty-five hundred ascents that have been made in Europe and America there have been but fifteen fatal accidents. — A new alloy of zinc and iron, containing 4.6 per cent. of the latter metal, is said to be remarkable for its whiteness and tenacity; and a new imitation of gold, prepared by a German chemist, consists of 58.86 parts of copper, 40.22 of zinc, and 1.92 of lead. — It is found that the wing of the bat and the ear of the white mouse are abundantly provided with nerves, apparently for the purpose of supplying, by means of a very refined sense of touch, the imperfection of vision; the number of nerve endings on each ear of the white mouse being estimated at six thousand. — An exchange says that "thirty-seven enthusiastic members of the 'Massachusetts Society for the Prevention of Cruelty to Animals,' made one horse draw them last week to a concert in aid of the Society at Salem." — M. Sezille has described, before the Agricultural Society of France, a method of preparing wheat, by which he claims that out of one hundred pounds of wheat twenty pounds more of bread are obtained than by the ordinary method of grinding and bolting, representing an increase of about twenty-five per cent. of the nutritive value. — The Westmoreland Coal Company are about to utilize the immense piles of "slack" or waste coal at their mines by converting it into coke; a new process for desulphurizing it having been devised. — The *Technologist* begins the new year under the name of *The Industrial Monthly*, but it is still furnished at the low price of $1.50 a year.

PSYCHIC FORCE. — The investigations on this subject by Dr. Crookes continue to attract a good deal of attention on both sides of the Atlantic. The general tone of the comments made by the scientific and secular press is, to say the least, very unjust to a gentleman whose scientific attainments are so high, and whose personal character is so irreproachable. The attack upon him in the *Popular Science Review* was particularly vulgar and conceited, and we are surprised that the editors should allow a paper of so abusive a character to appear in their valuable journal. Dr. Crookes has been identified with chemical and physical science for many years, and when he engages in any investigations his statements regarding results should be respectfully considered. The *Scientific Press*, of San Francisco, speaks of him as follows: —

"He braves the storm of ridicule which he has invoked with a boldness and spirit of candor which shows that he is an earnest man, and one determined to persevere in his line of investigation without fear or favor. His position as a scientist, his acknowledged intellectual attainments and power, and the spirit of candor which he manifests under peculiarly trying circumstances, cannot fail to command the respect of all who are following him in his investigations, whether in a spirit of sympathy or with the view of criticism.

"His latest experiments were conducted with more caution than those first published, while their apparent results are even more remarkable. In his last communication he remarks that so far as his other occupations will permit, he proposes to continue his experiments in various forms, and report from time to time their results. In the meanwhile he hopes that others will be induced to pursue similar investigations in a scientific manner.

"The Doctor applies some caustic remarks to the tender skin of Prof. Stokes, who presumes upon a severe criticism of the experiments, while he refuses to witness them in person, when he has ample opportunity and is urged to do so."

FILL LAMPS IN THE MORNING. — Scarcely a week passes, during the winter months, but we read accounts of frightful accidents from kerosene lamps exploding, and killing or scarring for life women and children. A simple knowledge of the inflammable nature of the fluid would probably put a stop to nearly all the accidents. As the oil burns down into the lamp, a highly inflammable gas gathers over its surface, and as the oil decreases, the gas increases. When the oil is nearly consumed, a slight jar will often inflame the gas, and an explosion is sure to follow, dealing with it death and destruction. A bombshell is not more to be dreaded. Now if the lamp is not allowed to burn more than half-way down, such accidents are almost impossible. Always fill your lamps in the morning; then you never need fear an explosion. — *National Family Almanac.*

Remarks. — Here is an Almanac, a "*Family*" Almanac, giving its readers to understand that they can have inflammable or dangerous liquids in their dwellings, and use them in their lamps, only they must "fill them in the morning," and not allow the lamp to burn but "half-way down." This whole paragraph is written in entire ignorance of the nature of burning liquids, and we are sorry to notice that it has been extensively copied by the press. Any fluid so inflammable that it must be poured into lamps in the *day time*, and but half the volume consumed in the vessel before it is refilled, is an *incendiary, perilous* liquid, and not a drop of it should ever be allowed to cross the threshold of any dwelling. *True, legal kerosene* is *not* such a liquid; no *gas* ever "forms upon its surface;" it is not "inflammable" at ordinary temperatures, and it may be poured into lamps at any time. Beware of volatile liquids, such as naphtha, "solar oils," sunlight oils, spirit-gas, etc., which are to be used under the conditions presented in this "*Family*" Almanac.

☞ THE January number of the *American Journal of Science and Arts* contains the following pleasant notice of this journal: —

"This monthly was established in 1866, and has now reached its sixth volume. It is 'devoted to the science of home life, the arts, agriculture, and medicine,' and its contents, presented under these heads, are interesting and instructive to a large class of readers. It numbers among its original contributors some of our first writers, who do good service in addressing, on matters of current interest in science, a larger body of readers than is reached by any other American journal of like character. The papers by Prof. C. A. Young on 'An Explosion in the Sun,' published in our last number, and also that on a preceding page, giving magnetometer indications at the time of the explosion, were copied from this Journal. For the use of the cut on page 70 we are indebted to its editors."

The *Lowell Daily Courier*, January 8, 1872, says: "*The Boston Journal of Chemistry* is full of familiar science, recipes, art information, agriculture, and other information. The name of the periodical may lead some to mistake its character. We think that the farmer or mechanic, or anybody else who takes an interest in the common processes of nature or art, or has a family growing up around him, may get a larger return for a dollar by subscribing for the *Boston Journal of Chemistry* than in any other similar way."

Mr. Theodore Phillips, of Red Bend, Illinois, under date of January 8, 1872, writes as follows: —

"There is no dollar that I spend during the year which pays me so well as that I spend for the *Boston Journal of Chemistry*. I would not be without it for *ten times* that sum."

☞ WE desire to return hearty thanks to our patrons for the very prompt attention to the "bills" sent out in our last number, and also for the many kind words of encouragement which almost every letter contained. No journal *can have* warmer or more enthusiastic friends than this has, and we fully appreciate the fact.

Of the thousands who have corresponded with the office the past month hardly a subscriber has ordered the JOURNAL stopped, and new names have come in upon us "like a flood."

LITERARY NOTES.

THE Harpers have just published Dr. Martyn Paine's *Physiology of the Soul and Instinct as Distinguished from Materialism.* It is founded on an essay published with a similar title more than twenty years ago, which attracted much attention; but in its present greatly enlarged form it is virtually a new work. The author believes in vital force, and in the soul as an entity independent of material organization; and he maintains his faith against all recent attacks upon it as ably and earnestly as when he first took up the sword in its defence.

The same publishers issue a new and enlarged edition of *The Poets of the Nineteenth Century*, which, in the good taste of its selections and the attractive form in which they are presented, has no rival among similar compilations; *Round the World*, a Boy's Record of his Travels, which many older writers might well take as a model in that line of literary work; and *Border Reminiscences*, by R. B. Marcy, U. S. A., the author of "The Prairie Traveller," etc.

Messrs. Scribner & Co. have begun a new series of their well-known "Library of Wonders," in an enlarged and improved form; and, what is even more to be commended, the English translation is carefully revised, and considerable new matter, of especial interest to American readers, is added. Two volumes, *Wonders of Water* and *Wonders of Vegetation*, have already appeared, and others will soon follow. Prof. Schele de Vere and Dr. J. W. Armstrong, President of the State Normal School, Fredonia, N. Y., are two of the editors engaged for the series.

Medicine.

MEDICAL PHILOSOPHY.

HAVE we a Medical Philosophy? Dr. Stearr (in the JOURNAL for November, 1871) says we hav not, and Dr. Briggs (in the number for December says we have. I presume these different opinion result from the *definition* that the writers severall attach to the term *philosophy*.

In the administration of medicine for the cure o disease we perhaps always philosophize to a certai extent; as, for instance, when we know a particula organ to be diseased, we either administer a medi cine which we believe will come in contact with tha organ, and by contact correct the morbid conditio of the organ, or else that will, by contact with som other organ or tissue, cause the elimination of som foreign or irritating substance, and thereby remov the *cause* of the disease. Some such philosophizin as this is perhaps pursued in every case: but suc could hardly be said to be a comprehensive philosophy of medicine.

To my mind nothing short of a definite knowl edge of the essential character of *health* and of *disease* and of the material change that transpires where either of those conditions supervenes upon the other can form the basis of a Comprehensive Medica Philosophy.

The following *hypothesis* will illustrate my idea.

It is a demonstrated fact that the molecules of all substances, whether organized or unorganized, are in a state of rapid undulatory motion. It is equally certain that the *rate* of molecular motion in different substances is different. We may therefore assume that the different organs and tissues that constitute the animal organization have each a particular rate of molecular motion; and I will assume, as an *hypothesis*, that this *normal* rate of molecular motion in all the tissues is *essential* to the state of health, and that any departure from this normal rate, in any one or more tissues, constitutes the state of disease. Let this hypothesis be granted, and it follows that the material change which a medicine should produce upon the organization, will be increased or diminished molecular motion. If such an hypothesis as the foregoing were sufficiently established, and the essential character of disease definitely determined, then the practice of medicine might be strictly philosophical.

For instance, we *know* that an increase of molecular motion is indicated by an increase of temperature. Having determined the temperature corresponding to the normal motions of the several tissues, the thermometer would indicate infallibly, in every case of disease, whether there is an excess or deficiency of molecular motion.

And because material motion can only be increased or diminished by material interference, in selecting a medicine for the cure of our disease we should seek for some substance that may be brought in contact with the diseased tissue, and whose molecular motion will, by interference with the molecular motion of the tissue, tend to reduce that to its normal state. If such a medicine could be found and brought in contact with the diseased tissue, and afterward eliminated without prejudice to other tissues, its administration might be said to be strictly philosophical.

With some such foundation as the above hypothesis for a Medical Philosophy, though the science would perhaps be more difficult than as at present pursued, yet the advance would be more steady and certain.

J. E. HENDRICKS.

DES MOINES, IOWA, *Dec.* 12, 1871.

FRENCH EXPERIMENTS WITH DISINFECTANTS.

A SPECIAL commission appointed by the French Academy of Sciences have been studying the vari-

ous methods employed for disinfecting the localities where contagious diseases prevailed during the late siege of Paris. Their report pronounces hyponitrous acid the most efficacious of all substances tested for this purpose. This agent completely destroys all germs of contagion, but it is itself so dangerous to health that extreme precautions are necessary in using it. The doors, windows, and other openings of the apartment must first be closed and sealed with gummed paper. The following proportions of the materials for generating the gas should be used: water, 2 litres; nitric acid, 1,500 grammes; copper turnings, 300 grammes. This quantity is sufficient for a room of 30 or 40 cubic metres. The materials are placed together in an earthenware vessel of eight or ten litres capacity, when the room is closed and left undisturbed for forty-eight hours. Even on entering the room at the expiration of this time the greatest care is necessary, and the person opening it should be protected by Galibert's apparatus. This treatment literally burns up all contagion, by the powerful oxidizing agency of the hyponitrous acid.

The commission state that carbolic acid is much more easily applied, far less dangerous and expensive, and seems to be equally efficacious. It is advised to mix it with sand or sawdust in the proportion of one part of the acid to three parts of the absorbent. Carbolic acid diluted with twenty-five to thirty parts of water was found very useful in daily sprinkling the floors and bedding of sick chambers. A case is alluded to by the commission, in which chlorine and the hypochlorites entirely failed to deodorize the gases given off by the bodies at the Paris "Morgue" during the heat of summer. These bodies were then sprinkled with an exceedingly dilute solution of carbolic acid, when the putrefaction was at once arrested and the foul odors removed. According to M. Devergie, water containing only the $\frac{1}{1000}$th part by weight of carbolic acid completely disinfected the dead-house in the hottest weather, even when it contained six or seven bodies.

CHLORALIANA.

CHLORAL-HYDRATE IN TETANUS NEONATORUM. — The *Lancet* states that Dr. Widerhoffer, of Vienna, showed lately to his class a child three months old, which was attacked by *tetanus neonatorum* at the end of the first week after birth, and was treated with chloral-hydrate in doses of one and two grains at the time of each onset of convulsions. It was in danger for a fortnight. During the intermissions of the spasms it was fed from the breast by its mother. It is now a fine, healthy-looking child. This is the sixth case (out of ten or twelve) that Dr. Widerhoffer has had recovered under treatment by chloral; under all other methods all his other cases died. Considering that Vogel and other German authorities on children's diseases had until quite recently never seen a case of this affection recover, such a success may be taken to indicate a real advance in therapeutics. Dr. Widerhoffer gives from two to four grain doses of chloral by the rectum, if the infant cannot take it by the mouth.

CHLORAL-HYDRATE AND BROMIDE OF POTASSIUM IN CHRONIC ALCOHOLISM. — Dr. F. Bradnack (*Buffalo Med. and Surg. Journal*) calls the attention of the profession to an original method of treating chronic alcoholism, namely, the combination of unusually large quantities of chloral-hydrate and bromide of potassium. He administered to a patient, suffering from six days' debauch, these remedies in the following proportion: ℞. Chloral-hydrat., ʒij.; Potassii bromid., gr. lxxx.; Syrupi simp., ʒj.; Aquæ, ℥ijss. M. Ft. haust. These enormous doses, 120 grs. chloral-hydrate, and 80 grs. of bromide of potassium, were given to the patient, merely dividing the mixture into parts, and diluting each with a little water, both doses being taken within five minutes. The effects were very gratifying. The patient had a tranquil and unbroken sleep for fourteen hours.

The details of this case appear to him to prove presumptively two points: 1st, That in cases of chronic alcoholism enormous doses of chloral-hydrate are not only tolerated, but are productive of great good; 2d, That a combination of bromide of potassium with chloral-hydrate furnishes a simultaneous sedative and hypnotic so excellent as to seem to indicate its use in diseases of this nature.

MEDICAL MEMORANDA.

REVACCINATION. — Upon the question when and how often people should be revaccinated, Dr. T. Snow Beck, of London, after careful investigation, has reached the following conclusions: —

1. It is necessary to vaccinate the infant in order to protect it during the period of childhood and youth.

2. We do not possess any data upon which reliance can be placed, and by which we can determine the value of any vaccination some time after it has been performed.

3. It appears clear, from the experience of the present epidemic, that the protective influence of vaccination becomes impaired during the period which elapses between infancy and maturity.

4. In order to maintain the protective influence of the cow-pox during life, it is desirable to repeat the vaccination after the individual has arrived at maturity.

STIMULANTS AND NARCOTICS. — The *Nation*, after remarking that little has thus far been accomplished in researches upon these agents, makes the following suggestions with regard to future investigations concerning them: —

"The effort of the future, with respect to stimulants and narcotics, will not be to prevent their abuse by forbidding their use — an effort as unwise and futile, if this judgment be correct, as the attempt to stop railway accidents by discouraging railways — nor yet to urge a vague precept of temperance upon the public mind; but rather to discover the laws of special adaptation in stimulants; in other words, to indicate the temperaments and constitutions to which particular *stimuli* are applicable, and the *stimuli* which are dangerous to particular constitutions and temperaments. Little effort has yet been made in this direction; but this is the path which the scientific investigation of the question of stimulants is hereafter to follow. The law of healthy stimulation is now the philosopher's stone of physiological science. We commend its search to investigators, feeling sure that the quest will be rewarded much more completely than that of the Floridian Fountain of Youth."

TREATMENT OF BOILS. — Mr. James C. Dickinson, in an interesting pamphlet on "Boils, their Varieties and Treatment," recommends in the treatment of the ordinary boil, when the tendency to break out in crops is observed, to give ten grain doses of quinine; when the quinine fails, he applies an ointment composed of extract of belladonna, powdered opium, and rosin, spread on wash-leather about the size of a shilling, to each boil. This unguent, he says, at once allays pain and irritation, and promotes absorption. Internally, he prefers the lactate of iron and change of air. In cases of "recurrent boils," he uses Erasmus Wilson's ferro-arsenical mixture with the best results.

THE CAUSE OF HYDROPHOBIA. — Although no sure remedy for hydrophobia has been found, it appears that some important discoveries respecting the nature of the disease have been made lately in Russia. A Russian official journal publishes a communication on the subject from a paper contributed to the archives of judicial medicine. "Since," it announces, "the Professor of Pathological Anatomy, M. M. Rudnow, undertook in 1869 the lectures on the pathological anatomy of animals for veterinary students, he has given particular attention to the subject of canine madness, so many cases of which come within the scope of judicial veterinary practice, while hitherto so few firm bases for a satisfactory diagnosis of the disease have been obtained by opening the animals. Being convinced that sure results could only be arrived at by means of the microscope, he continued his researches, and with the aid of that instrument made a surprising discovery. The main cause of rabies is the anatomical alteration of the kidneys through their parenchymatous inflammation. This differs from other forms of inflammation in that the whole epithelium of the kidneys is diseased at the same time, and that it easily degenerates, while the lobes of the kidneys fill at the same time with a fatty substance, by which the uniformly fatal issue of hydrophobia is brought about." Supposing the cause of the disease to be thus ascertained, it is to be hoped that as little time as possible will be lost in discovering a cure for it.

HYPODERMIC INJECTIONS. — Dr. E. Borck, in the *Medical Archives*, sums up the advantages of hypodermic injections as follows: —

1. Promptitude of action — not unfrequently a most important object.

2. Greater certainty and exactness of administration. There is no danger of a portion being ejected, commingled with the saliva, or the entire rejection of the medicine, as when given in the ordinary method by the mouth.

3. A saving of the drug; but one third to one half, or even less, of the ordinary dose being required.

4. The facility by which medicines can be administered by this method, when they could not by the mouth, as in tetanus, coma, delirium, etc.

POPULAR REMEDIES. — We find the following in one of our exchanges, where it is given in all soberness: —

"*Cure for Ague.* — A teaspoonful of common salt taken in water, and a teaspoonful deposited inside the stocking next the foot, as the chill is coming on, will cure fever and ague.

"*Cure for Sty on the Eye.* — Rub the sty over with a plain gold ring, and the sty will disappear. There is no superstition about this. Let the afflicted try it.

"*Cramp in the Leg* may be cured, and prevented, by simply wearing around the ankle a cord composed of six or eight strands of raw cotton — candlewick is best."

PREVENTION OF SCARLATINA. — Dr. W. M. Searcy (*Nashville Medical Journal*) thinks, if, when physicians are called to cases of scarlet fever from day to day, they will carefully examine the tonsils of those of the family who have not yet taken the disease, they will generally find the tonsils exhibiting more or less redness and enlargement. In all such cases he at once applies a solution of nitrate of silver — dr. i. to oz. i. distilled water — every day until signs of amendment are visible, and then every other day until the local disease disappears. When the glands are much enlarged and red, he gives a few grains of calomel, followed in a few hours by castor-oil, or a saline. He gives thirty-three instances of individuals who never experienced an attack, although directly exposed, after the employment of the caustic as above recommended.

BROMINE AND KEROSENE APPLICATIONS IN CANCER. — At a recent meeting of the British Medical Association, Dr. Wynn Williams read a paper "On the Treatment of Cancer of the Neck of the Uterus and Allied Structures by the Injection and Application of Bromine." "The author commenced by making some remarks on the spontaneous removal of malignant tumors, from the study of which he was led on to the injection of bromine into can-

cerous tumors of the uterus and other parts. He stated that the eight cases published in the last volume of the 'Obstetrical Transactions' still continued well. He entered into full details as to the manner of injecting these deposits, and the care required in the use of bromine both as an injection and application, and that before its use the surrounding parts should be well protected by a solution of soda. He exhibited the various instruments he had had made for the injection of bromine. He gave the history and successful treatment of a well-selected case of medullary carcinoma of the uterus in the state of disintegration and ulceration by this method. He also gave the particulars of a case of epithelioma of the lower lip which had been previously removed by operation. On the return of the disease the patient was sent to Dr. Wynn Williams, who, by two injections of bromine, caused the entire and, so far, permanent removal of the disease."

Dr. Sedgwick S. Cowper writes that he has found "the vegeto-mineral oil, known in Australia as kerosene, wonderfully curative in the treatment of ulcerated and cancerous wounds."

SELECTED FORMULÆ.

GLYCEROLE OF STARCH. — This preparation is made by rubbing well together one part of starch in eight of glycerine; then heat the mixture gradually to 240° Fahr., constantly stirring until a translucent jelly is formed. The glycerole of starch is a capital substitute for lard in making ointment. Moreover, this preparation of starch seldom becomes spoiled, and keeps for a very long time. As a local remedy in many acute affections of the skin, and to prevent the pitting of small-pox, it deserves a more extensive trial.

SYRUPUS ASSAFŒTIDÆ COMPOSITUS. — A writer in the *Journal of Pharmacy* gives a formula which obviates the great objection felt by most patients to the disagreeable smell and taste of assafœtida, and which has prevented to a great extent the more general use of this valuable drug. At the same time its medical qualities are enhanced by composition with syrup of wild cherry, possessing the valuable therapeutic properties of both.

℞.	Infusi Pruni Virginianæ . . .	Oj.
	Assafœtidæ	ʒj.
	Sacch. Albi	℥xxiv.
	Magnes. Carb	℥ij.

Rub the assafœtida and magnesia, with the infusion gradually added, so as to make a uniform mixture, and filter; to this, transferred to a bottle, add the sugar, and agitate occasionally until it is dissolved. As a result we have a handsome syrup, which does not differ in appearance from the syrup of wild cherry.

The property possessed by the volatile oils of bitter almonds, cherry, laurel leaves, bark of wild cherry, etc., containing hydrocyanic acid, of removing the odor of assafœtida has long been known, and advantage taken of this property by M. Maheir, a French pharmaceutist, to remove the odors from mortars and bottles with which it came in contact; but the fact has never before been applied to its administration as a medical agent.

AN EFFICIENT DIAPHORETIC. — Dr. T. Osborn recommends the following diaphoretic as having been found useful in the region of Alabama in which he has practised physic: —

℞.	Chloroformi . . .	aa. oz. ss.
	Spts. etheris nitrosi . . .	
	Tinc. opii camphoratæ . . .	
	Vini antimonii . . .	
	Aquæ	oz. ij. M.

For adults, one table-spoonful every hour until the fever abates.

FOR CHRONIC DYSENTERY. — Dr. J. S. Warren, Louisville, Ky., (*Richmond and Louisville Medical Journal*) says: In chronic dysentery we have good effects from the following prescription: —

℞.	Vin. ipecac.	
	Tr. nux. vom. . . .	aa. dr. ij. M.

S. — Twenty drops three times daily, either before or after meals, as may best agree with the patient. One patient, he says, who had taken everything that is usually given in dysentery, was completely cured by the above. The effect of the remedy is to produce temporary catharsis — but this is easily controlled.

A MEANS OF ARRESTING THE SPREAD OF SMALL-POX. — John Day, M. D. (*Australian Medical Journal*), in a paper "On a Means of Arresting the Spread of Small-Pox," read at a meeting of the Medical Society of Victoria, explained his *modus operandi* of perfectly destroying the germs by which small-pox is propagated. His belief is, that the virus of small-pox is always associated with pus-cells, and the only way in which it can be destroyed is by oxidation. He proposes the use of peroxide of hydrogen as the agent for rapidly and thoroughly oxidizing and destroying the virus-germs given off from the bodies of small-pox patients. Peroxide of hydrogen, which, according to Schönbein, is composed of antozone and water in a state of chemical combination, undergoes a remarkable change in the presence of blood, and by mere contact with the corpuscles, its antozone is rapidly transformed into ozone — the oxygen of combination.

The particular form in which he would recommend the use of peroxide of hydrogen is that known as ozonic ether — being a compound of absolute ether and peroxide of hydrogen. It is highly volatile, and may be diffused even through very large apartments, such as the wards of hospitals, by means of a spray-apparatus. It quickly destroys sulphuretted hydrogen and other noxious gases, and, when once diffused, it is very persistent in its action.

As collodion, cold cream, and lard are occasionally used as topical applications in the treatment of small-pox, he mentions that ozonic ether can be mixed with any of these substances without undergoing any perceptible change in its chemical properties.

Remarks. — The above item has appeared in several medical journals, and many physicians have sent to us for *peroxide of hydrogen* and ozonic ether. We have to say that peroxide of hydrogen is an agent often prepared in the laboratory in small quantities, but the great expense and trouble involved in its preparation prevent it from becoming an article to be used in medicine, or sold in the market. It is a dangerous agent to handle. The same may be said of ozonic ether. This may be readily prepared by inserting in a mixture of the vapor of ether and air red-hot glass rods, but the process is dangerous, as explosions are apt to result. The use of the agents as described by Dr. Day is impracticable, and we would say further, if practicable, unnecessary. The thorough employment of carbolic acid or carbolate of lime is effective in destroying germs of disease, and they are cheap and safe. Sulphurous acid is also very effective, but it also is unsafe unless used with great care.

DECISION AND QUIETNESS IN THE SICK-ROOM. — Consult your patient's wants, but consult him as little as possible. Your decision need not be very obvious and positive; you will be most decisive if no one suspects that you are so at all. It is the triumph of supremacy to become unconsciously supreme. Nowhere is this decision more blessed than in a sick-room. Where it exists in its genuineness, the sufferer is never contradicted, never coerced; all little victories are assumed. The decisive nurse is never peremptory, never loud. She is distinct, it is true — there is nothing more aggravating to a sick person than a whisper — but she is not loud. Though quiet, however, she never walks tip-toe; she never makes gestures; all is open and above-board. She knows no diplomacy or *finesse*, and of course her shoes never creak. Her touch is steady and encouraging. She does not potter. She never looks at you sideways. You never catch her watching. She never slams the door, of course, but she never shuts it slowly, as if she were cracking a nut in the hinge. She never talks behind it. She never peeps. She pokes the fire skilfully, with firm, judicious penetration. She caresses one kind of patient with genuine sympathy; she talks to another as if he were well. She is never in a hurry. She is worth her weight in gold, and has a healthy prejudice against physic, which, however, she knows at the right time how to conceal. — *Good Health.*

HOW TO LIVE LONG. — Shakespeare says that "our little life is *rounded* with a sleep," and the New York *Tribune* tells of a California man who has found the secret of longevity in sleeping in a circle, like a cat. This philosopher, whose head, like his back, must be a trifle weak, declares that he has prolonged his life by sleeping with his finger-tips touching his toes, and has invented a machine to hold the body in that graceful and pleasant position. He contends that the "vital electric currents" — on the principle, we suppose, of the smoke-consuming stove — "are thus kept in even circumflow, instead of being thrown off at the extremities and wasted." There is no patent upon the great discovery, and any one with a sufficiently supple back is of course free to try the experiment.

THE *Georgia Medical Companion* bestows upon Dr. E. Cutter's recent pamphlet, "Contributions to the Treatment of the Uterus," the following deserved compliment: —

"The pamphlet is certainly the most complete and exhaustive monograph upon the subjects proposed, which we have seen, and justice requires us to say they are most admirably and satisfactorily discussed by the author. The pamphlet should be in the hands of every physician who desires to be well informed upon the subjects of which it treats."

VACCINE VIRUS. — We desire to state that we cannot supply vaccine matter to physicians, and they will please not send to us for it. At great inconvenience we have endeavored to meet their orders until this notice could appear, as we knew the demand was urgent. It was stated two years ago, in the JOURNAL, that we could not longer supply it, and now we repeat the notice.

CINCHO-QUININE. — U. N. Mellette, M. D., of Williamsburgh, Indiana, under date of January 9, 1872, writes as follows of this agent: "I have used about 30 ounces of cincho-quinine in my practice, and I like it very much. It can be made into a syrup for children with facility, and in this form I employ it largely." Dr. C. C. Comstock, of St. Louis, under date of November 28, says: "I am using cincho-quinine in my practice, and am convinced that it is equal if not superior to quinine. Many of my patients who cannot take quinine can bear cincho-quinine, as its taste is not disagreeable, and it does not produce headache. In treating children, where quinine is indicated I have substituted cincho-quinine with satisfactory results."

The manufacturers, J. R. Nichols & Co., chemists, Boston, will send by mail to any physician in the United States, a packet holding $\frac{1}{2}$ oz. of the agent, for trial, upon receiving an order, inclosing a ten-cent postage stamp.

Boston Journal of Chemistry.

VOLUME VI. BOSTON, MARCH, 1872. NUMBER 9.

Familiar Science.

CHEMISTRY OF A DROP OF VINEGAR.

To the popular mind there are many "ways hat are dark" in the ordinary operations of nature, ınd a very deep mystery hangs over the changes ınd movements which occur spontaneously in ome of the most common substances. The fact hat sweet substances like sugar and molasses ıre capable of changing into *sour* vinegar, in a ew weeks, without any special human interfernce, is perhaps as great a mystery as any which s forced upon the attention. Whilst it is observed that there are many solids and liquids in common use, of a sweet or agreeable taste, which apidly become sour, it is also noticed that no sour substances ever become sweet, unless it may be in the case of the juices of some fruits which change during the process of ripening. Vinegar once formed from sugar never goes back again o the saccharine state; all further changes are lownward towards the inorganic condition. If we add sugar to the liquid, it does not impart to t a taste of pure sweetness, and it remains a listinct body, having no affinities for the acid vith which it is incorporated. It is not surprising that sugar should be pleasing to the sense of aste, and be regarded as a luxury among all ations; but that vinegar, having precisely the pposite influence upon the gustatory nerves, hould be freely used in connection with food ubstances, and held to be an almost indispenable condiment, is a matter not a little perlexing. It is clear that the appetite for acid ubstances is a natural one, and that vinegar, ke sugar, is capable not only of gratifying the ense of taste, but of meeting certain wants or onditions of the system which are essential to ealth.

The use of vinegar among the ancients was ery common, and its antiquity is so great that it impossible to learn when it was first employed. rom the writings of Moses we know that the raelites used it freely, and among the Eastern ations vinegar, as a condiment and a cosmetic, as highly esteemed. In the entire absence of hemical knowledge, the formation of the acid om saccharine liquids must have greatly uzzled the old philosophers of Greece and ome, and we have no doubt they often shook eir wise heads, and stroked their beards, as ey watched with intense interest the fermentave changes which resulted in the production of e acid. We must not, however, boast extravgantly of our modern chemical science, since ere are some points in the wonderful process of cetous fermentation which are not yet quite satfactorily cleared up. But the practical details d chemical changes that are connected with e formation of acetic acid are well understood, ith the exception of its production when wood subjected to distillation, and this series of reactions have had much light thrown upon them by recent investigations.

Vinegar must be regarded as the most interesting of all the organic acids, not excepting the malic. Its industrial uses are very numerous, as under the proper name of acetic acid it is employed to form many compounds of the highest importance in the arts. It exists ready formed in the sap of nearly all plants, and probably in some of the liquids dependent on the animal economy, but the quantity is very small. In the artificial production of vinegar it is necessary that alcohol, another very remarkable organic product, be present in the liquid, as it is by the oxidation of this agent that the acid is produced. The series of changes which occur when sweet liquids are transformed over into vinegar are of a complex nature, and somewhat difficult of being made plain to the general reader, but we will endeavor in as brief and comprehensive manner as possible to point out these changes.

In order that the acid may be formed, there are two fermentative processes necessary; first the *vinous*, by which alcohol is produced, and second the *acetic*, from which vinegar results. Sugar in itself is a true chemical compound of three elements, carbon, hydrogen, and oxygen. Hydrogen and oxygen in combination form water, and it is a curious circumstance that the hydrogen and oxygen, as they exist in sugar, are in such proportions that if they were united they would form *water;* hence it might appear that if we could remove the charcoal or the carbon element, simple water would remain from a union of the other two. This would lead us to regard sugar as a compound of *charcoal* and *water*, and indeed, having regard strictly to its chemical constitution this is true, but it really contains no water ready formed, as it is made up of the three elements in direct combination. Now, let us examine this group of atoms, and notice what an extended series of curious products result, when we set them in motion by introducing disturbing agencies. This series of changes by no possibility can result in the production of a higher type of organization, but the new bodies will form a kind of descending scale, gradually decreasing in complexity of composition.

Into a liquid containing sugar, we will introduce some curious germinal matter, called *ferment*, the nature and action of which will soon be described. Upon exposing the solution in a room kept at a temperature of 60° or 70° F., we shall observe after a few hours that it has become somewhat turbid, and that minute bubbles of gas rise from all parts of the liquid, ascend to the surface, and escape into the room. This gas is carbonic acid, the same that results from combustion, and which passes up and out of every chimney connected with coal or wood fires. The evolution of gas is copious, and goes on rapidly increasing for a certain length of time, depending very much upon the warmth of the surrounding air. After a while the action slackens, the liquid once more becomes clear, and if we now draw out from the vessel a portion, it will be found upon examination to have lost in a great measure its sweet taste, and to have acquired another quite distinct. It has become an intoxicating liquid, and by distillation we obtain a colorless, inflammable spirit, easily recognized as *alcohol*. This alcohol is a true ternary substance like sugar itself, but *simpler in constitution*. In the experiment we have broken up the unstable, highly organized substance, sugar, by the disturbing agency of ferment, and from the disarranged atoms have formed another body, totally dissimilar in physical character and influence upon the animal economy. This change is spontaneous, and must inevitably occur in all liquids containing sugar, if they also contain a nitrogenous body capable of putrefying or passing into decay, and if they are allowed to remain in a warm atmosphere. Cider, the expressed juice of apples, is a liquid which contains much sugar, no matter how sour the apples may be from which it is made. It also contains albuminous or nitrogenized substances; so if the liquid is allowed to remain in a warm room, the particles of sugar become disturbed, a kind of family quarrel is engendered by the mischievous ferment, the whole household of sugar atoms is broken up, and they are forced to aid in building up a new substance, which is the cause of more misery than all the physical maladies that afflict mankind.

It will be understood that although vinegar is produced from cider, it cannot be formed from it direct; that is, it is impossible to change cider directly into vinegar. The sugar must first be changed into alcohol, and then the alcohol is changed into vinegar. It will also be understood from this statement, that when vinegar is made from rum or whiskey, the sugar from which the alcoholic liquids come has passed one stage in its descent towards the acid condition, and hence it can be produced from these liquids direct. Before proceeding to notice the interesting changes involved in the acetous fermentation, let us consider the nature of the agent through which the vinous is set up. This ferment is a kind of vegetation which springs up in liquids containing nitrogenized bodies, and also it exists or is spontaneously developed in the organs of plants. If we take a little of the common household yeast, and diffuse it in a few drops of grape juice or new cider, and then place a drop of this between two thin plates of glass, with a little mastic varnish at the edges to prevent the evaporation of the water, we have a suitable arrangement for studying the ferment plant under the microscope. In watching the changes that occur through several days, we shall observe that the little globule, or plant, no more

than $\frac{1}{100}$ of a millimetre in size, is capable of reproducing itself almost indefinitely. The single atom in the field of the microscope in the course of a couple of hours begins to swell, and in six hours more a new globule has proceeded from its side, perfect in every respect like the first; from this another birth takes place, and this budding and developing process goes on so long as the albuminous matter lasts, and in large masses of fermentable matter millions and billions of the plants are produced every day. The ferment globules are composed of a solid envelope inclosing a liquid; or they may be regarded as cellules, holding a liquid and having their walls covered with a mucilaginous substance. How they act, in the work of breaking up organic compounds like sugar, is not precisely understood. It is difficult to closely investigate the changes under the microscope, as the evolution of bubbles of carbonic acid in the saccharine solution is so copious that observation is in a great measure cut off.

This strange ferment is not only found in sugar solutions, but is always present when animal matters spontaneously decompose. What is called *putrefaction* or decay, in flesh, gelatine, eggs, cheese, blood, etc., is indeed *fermentation*, as the sugar in these substances is transformed into alcohol and carbonic acid. Alcohol is always produced from the carcase of a dead cat, dog, or horse when left to undergo spontaneous decomposition. It is a product consequent upon the changes which result from *death*, and we may say that its habitual use as a beverage tends to disorganize the vital functions, and to rapidly place the human body in a condition from which a portion of itself will be resolved into the agent which caused its destruction.

It has been intimated in this discussion that apples from which cider is produced, and from which vinegar results by the process of fermentation, contain the germs of ferment, and the inquiry may arise, Why do they not act upon the sugar contained in the juices, and destroy the fruit? They do, whenever from any cause abrasions or holes occur in the skin. An apple, so long as the skin is sound, is protected from atmospheric oxygen, and the ferment cannot act without the contact of this element, and so the apple is preserved. If a worm bores a hole through the skin, or an insect ruptures it in any way, oxygen is admitted to the juices, the ferment starts into life, and the apple *rots*. A rotten apple is *sour* because it contains true vinegar. The same process has gone on in the apple that goes on in cider when vinegar is formed from it. First alcohol was produced in the fruit, and from this vinegar, and following the descending scale the vinegar, if collected and subjected to certain processes, might be changed into pyroacetic spirit or acetone.

In using the term *acetous fermentation*, it must be understood that we use it for the sake of convenience, and because it is commonly used in reference to vinegar making. The acetous change is brought about by agencies which are unlike those producing the vinous, and we doubt if the term *fermentation* is a proper one to apply to it. A great variety of opinions prevail among chemists regarding this action, but we do not design to be betrayed into any extended discussion upon the subject. It is enough to say that in order that alcohol may be changed into vinegar, access of air is necessary, and that the air must be brought in direct contact with the liquid. Vinegar making is an oxidizing process, and hence it is important that the oxygen of the air should be brought in contact with saccharine liquids, which are distributed over the greatest extent of surface, for it is only on the surface that vinegar is formed. A barrel of cider exposed to the air out of doors in summer is converted into vinegar very slowly, because the air can only act upon the surface, and if there was no *motion* in the liquid, it would not change in the course of a century. Heat causes convective currents, which tend to displace the liquid, and bring new portions to the surface constantly.

A barrel of cider, which would require six months to change under ordinary conditions, can be acidified in a week, by allowing the liquid to trickle slowly over or through a mass of clean shavings so as to expose it to a great extent of surface. In this country preference is given to cider vinegar made by the slow process, as adopted by our farmers, but very little of this is found in the market, in cities. The vinegars sold by dealers are made in a variety of ways, some of which are in the highest degree objectionable. A vinegar is produced from cheap molasses which costs but two or three cents a gallon, and which is sold at twenty or twenty-five cents. It is easily made by largely diluting molasses with water, adding yeast to promote vinous fermentation, and when the alcohol is formed, oxidizing it by distributing the liquid over a great extent of surface. Vinegar of fair quality can be made in this way in *thirty-six hours* after the vinous fermentation is completed.

Much sour liquid is sold called vinegar, which is made from sulphuric acid, or oil of vitriol. The cheap acid is added to water until its taste is regarded as desirable, and then it is colored with burnt sugar, to make it resemble true cider vinegar. This is a fraud of a serious nature, and hundreds of unsuspecting consumers are greatly injured in health by its use. We have found in vinegar oxalic acid, which is a fatal poison when used to any considerable extent. This acid is now so cheap that its employment in the manufacture of factitious vinegars is quite common. In view of the alarming sophistications and substitutions connected with the vinegar trade, we think the legislative bodies of the several States should pass stringent laws regarding the offence, and appoint inspectors whose duty it shall be to examine all specimens offered for sale.

Vinegar used as a condiment may be understood from the properties of acetic acid. When in a strong or concentrated state, it acts on living tissues as a caustic, producing redness, heat, and rapid inflammation of the skin; when properly diluted, and used in moderation, it promotes digestion. It has the power of dissolving gelatine, and this shows how it assists in the digestion of veal, young meats, and fish. It also aids in the digestion of crude vegetables, as cabbage and salads. It is curious that our instincts call for the condiment, in connection with the use of these kinds of food. Many young girls have an unnatural craving for vinegar, and the vegetable substances preserved in the liquid, limes, cucumbers, onions, etc. The injury to the health resulting from indulgence in such indigestible substances is undoubtedly very great, and parents should promptly interpose their authority ar prohibit their use.

The fact that animal life is so frequent observed in vinegar is not a little perplexir to many. An acid so potent and caustic woul not apparently be a congenial medium in whic animals might live and thrive, and yet the liqui as seen upon our dinner tables is often crowde with a mass of living, active creatures, whic can almost be seen with the naked eye. Tl *Anguillula aceti*, or vinegar eel, is an animalcul possessing wonderful tenacity of life, and it als is one not found alone in vinegar, but in a larg number of substances while in the process o decay. It is almost impossible to destroy then for if we take a mass of the eels mixed up wit the ova and expose them to the scorching su of midsummer, dry them thoroughly, place the in a mortar and grind them to the finest powde we do not destroy life. If we place a little this powder in a few drops of water, we soo discover some chemical change going on, an suddenly the whole is converted into colonies o living eels. Acids and corrosive liquids do n destroy them, and agencies fatal to most othe creatures have no effect upon them. Ho astonishing are these facts!

The eels are never found in the best, or i well manufactured vinegars, as they cann exist without something to feed upon, and in th removal of all mucilaginous or albuminou matters from vinegar, no food remains for then Vinegar eels are not only objects of curiosit and study to naturalists and others, but they ar often turned to account by the vagabond quack that infest cities and towns, and prey upon th ignorant and confiding, who resort to them wit the view of obtaining relief from certain maladies The ingenuity of quacks is in no way mor clearly shown than in their manipulations wit these wiggling animalcules.

Through the *Doctor's (!)* flaming advertise ment, the victim is made acquainted with hi place of business, and he forthwith seeks out th den and submits himself to examination. He i gravely told that his system is *full of worms*, th result of his indiscretions, and that the doom o Herod awaits him. To frighten his victim, an gain perfect control, he obtains a little of som one of the secretions of his body, and placin this upon a glass slide which has been previousl covered with a film of *sour paste*, he adjust it under a microscope, and lo! there are th worms; the dupe can see them for himself The dismay of the poor victim can be better imagined than described; he is ready to part with all his money to be relieved from his dreadful condition, and the quack has him in his power Sour paste always contains millions of the *Anguillula*, and a thin film may be spread upon a glass slide and dried so as not to be observed. As soon as the saliva or other secretion is added to the paste, the dormant energies of the little creatures are aroused by the moisture, and they appear full of life. This is but one of the many forms of deception practised by the quacks of this and other cities.

In this essay upon a drop of vinegar, we have but touched upon some of the most interesting points connected with its chemical history. To present even these few points with much fulness of detail would require more space than we have at command.

THE SOLAR ECLIPSE OF DECEMBER 12, 1871.

BY PROF. C. A. YOUNG.

It is too early as yet for us on this side of the water to attempt anything like a summary of the results of this eclipse, and still perhaps enough of interest has already come to hand to be worthy of record in the pages of the JOURNAL OF CHEMISTRY.

The shadow of the moon struck the earth on the morning of December 12, in the Arabian Sea, near the mouth of the Persian Gulf, and thence travelled to the southeast across the southern point of India, and the northern extremity of Ceylon, passing over the Straits of Sunda, and very near the city of Batavia, touching the northern coast of Australia, and finally disappearing in the Pacific. The duration of the darkness ranged from about two minutes in India, to four in Australia.

In Australia, the parties sent out from Melbourne and Sidney were disappointed by bad weather, but so far as heard from, the observers in India and Ceylon were all favored in this respect.

The different telegrams which have thus far come to our notice, run as follows: —

From Col. Tennant, F. R. S., to Dr. Huggins: —

"DODABETTA, NEAR OOTACAMUND, Dec. 12, 9.15 A. M.

"Thin mist. Spectroscope satisfactory. Reversion of lines entirely confirmed. Six good photographs."

Dodabetta is on one of the peaks of the Neilgherry Hills about 8,600 feet above the sea. It seems to be the most western of the stations occupied. The clause about the reversion of lines refers to an observation of my own, made during the Spanish eclipse of 1870 — an observation which had been somewhat discredited in certain quarters.

From N. R. Pogson, of the Madras Observatory, who was stationed at Avenashy, about forty miles southeast of Dodabetta, but at a much lower elevation, we have the following to the Astronomer Royal: —

"Weather fine; telescopic and camera photographs successful; ditto polarization; good sketches; many bright lines in spectrum."

From Janssen, the French astronomer, to the Secretary of the French Academy of Sciences:

"OOTACAMUND, Dec. 12, 1871.

"Corona spectrum attesting matter beyond sun's atmosphere."

This is decidedly Frenchy. The fact indicated by the telegram was ascertained at the American eclipse of 1869, and fully confirmed by nearly all the observers of the eclipse of 1870. No *Frenchman*, however, had before made the observation, and so it is telegraphed as if it were a new discovery.

Another telegram from the same gentleman, dated December 18, reads thus in English: —

"Great atmosphere of highly rarefied hydrogen above the chromosphere."

So far as the existence of an extensive atmosphere above the chromosphere is concerned, this has been well-known for more than eighteen months. If it however really consists to a large degree of hydrogen, the fact is new and important.

From the English Eclipse Expedition which went out under the charge of Mr. Lockyer, and was divided into several parties stationed at various points in Northern Ceylon and along the neighboring Indian shore, we hear as follows: —

"MANGALORE, *Dec.* 16.

"The eclipse observations have been very successful. The extension of the corona above hydrogen apparently small. Five admirable photographs have been taken."

The address and signature of this telegram are not given; I suppose it to be from Mr. Lockyer himself.

From Mr. Davis, the photographer of this English party, to Lord Lindsay, who equipped the photographic corps at his own expense, besides contributing many valuable instruments for other observations, we have this telegram: —

"MANGALORE, BAIKUL.

"Five totality negatives; extensive corona; persistent rifts; slight external changes."

Finally, Dr. Oudemans of Batavia telegraphs to the Royal Academy of Sciences at Amsterdam: —

"Preliminary results: corona distinctly seen, pure white rays, dark rifts as far as the moon's limb; no outline of chromosphere; radial polarization of corona; no magnetic disturbances; moving shadows positively observed."

Very soon now we shall also begin to get the fuller accounts of the observers in letters to the various scientific journals. The London *Daily News* for January 15, which has just been received from a friend in England, contains the first communication of the kind that I have seen, in the form of a long letter of more than three columns from some gentleman of Mr. Lockyer's own party. The letter is mostly taken up with an account of the voyage, preparations, etc., but I give an extract describing the eclipse.

After picturing the terrifying effect of the advancing eclipse upon the superstitious natives, he continues: —

"It is now time to return to the fort (where was placed the observatory). Capt. Maclean (Maclear?) announces bright lines in abundance. Mr. Lockyer has barely time to observe these, whisper a word or two, and reach the large spectroscope, before he exclaims 'Steady,' the signal agreed on for commencing the counting of time. Instantly everybody in the fort heard Capt. Bailey's clear voice ringing out 'You have 120 seconds,' and there in the leaden-colored, utterly cloudless sky shone out the eclipsed sun! a worthy sight for gods and men.

"There, rigid in the heaven, was what struck everybody as a decoration, one that an Emperor might fight for, a thousand times more beautiful than the Star of India even where we are now, a picture of surprising loveliness, and giving one the idea of serenity among all the activity that was going on below, shining with a sheen as of silver essence, built up of rays almost symmetrically arranged around a bright ring above and below, with a marked absence of them right and left, the rays being composed of sharp radial lines separated by furrows of markedly less brilliancy."

The writer goes on with an account of the observations, but as continually happens when popular writers describe scientific work in the popular journals, things are pretty badly mixed up, and as it stands the account is tantalizingly unintelligible. One or two points are clear: the 1474 line was seen longer than F; vertical polarization was observed over the whole corona with the Savart polariscope. The description of the other polariscope results is confused. The corona was observed by Mr. Lockyer through a train of several prisms; an observation which I think must be decisive of many important points, although I can make nothing of the result as it stands: "Four circles, 1474, same size and faint."

Mr. Lockyer, also observing the structure of the corona with the telescope, followed it for more than three minutes after the sun returned.

Putting everything together, it would seem that the principal results of this eclipse are simple confirmations of conclusions which had been already attained on previous occasions, but were not entirely acquiesced in by all astronomers.

It will hardly be disputed any longer that the sun's atmosphere extends very high above its luminous surface, and that the dark lines of the ordinary solar spectrum originate in the lower strata of this atmosphere.

No one will longer claim that the corona is mainly an effect of our own atmosphere. I think I may go further, and say it will be universally admitted that the corona, — ring, rays, rifts, streamers, and all, — is a true solar appendage, whose appearance and extent are only slightly modified by our own atmosphere. But perhaps this is premature; at any rate, the comparison of the numerous photographs and other observations can hardly fail to settle the question forever.

As to the polarization of the corona light, there seem to be the same puzzling inconsistencies between different instruments and observers as hitherto, and a very interesting and difficult problem must be solved by physicists, before they can be fully reconciled.

It may easily happen also that the comparison of the various observations may lead to some entirely new discovery; almost certainly some new question will be raised which can be settled only at the next eclipse.

DARTMOUTH COLLEGE, *Feb.* 5, 1872.

NOTES IN FAMILIAR SCIENCE.

EFFECTS OF FROST ON PLANTS. — It has been a disputed question whether plants killed by frost die in freezing or in thawing. That the former is the case, at least in some cases, has been satisfactorily demonstrated by Professor Göppert, of Breslau. The flowers of certain orchids, as, for example, the milk-white blossoms of *Calanthe veratrifolia*, produce indigo, but only by a chemical reaction that takes place upon the death of the parts. When they are crushed, or the vitality of the cells is otherwise destroyed, they turn blue at once. Now this change of color occurs immediately upon freezing, which proves that life then ceases. Certain other species are said to show the same thing.

THE BIG TREES OF AUSTRALIA. — Recent explorations show that the great Australian trees exceed in height, though not in circumference, the giants of California, though some of the Australians must be regarded as very respectable in girth as well as height, the hollow trunk of one of them being large enough to admit three horsemen to enter and turn without dismounting, while they led a fourth horse. A fallen tree in Victoria was measured not long since, and found to be 420 feet long; another measured 480 feet. The highest trees on the Sierra Nevada, California, yet discovered, reach only 450 feet, the average size being from 300 to 400 feet in height, and from 25 to 34 feet in diameter. The wood of these trees closely resembles red cedar, and

the reddish brown bark is sometimes 18 inches thick. The age of some of the oldest has been computed at 2,000 years.

Preparation of Oxygen. — In the preparation of this gas from chlorate of potash and black oxide of manganese, it is recommended to use a thin iron retort, and apply the heat rapidly at first, gradually lowering the temperature as the gas is evolved. If the mixture is very rapidly heated, one part of it will be entirely decomposed without fusing before another part has reached the required temperature, and so the evolution of the gas will be gradual and steady. But if the heat be more gradually applied, the entire mass may be slowly fused, with very slight escape of gas; but when once the temperature for this is reached, the action goes on simultaneously throughout the mass, and is then of a very violent character. The melted material is also liable to froth up and close the outlet; but by applying the heat rapidly all difficulty is avoided. After being used, the retort, if made of thin iron, should be cleaned out by breaking up the residuum with a sharp stick, rather than by washing, as is usually done. By doing this, it lasts much longer than it otherwise would do.

PAPERING ROOMS.

Don't try to paper with a carpet down. Make paste, cut bordering, and the paper, the day before. If the wall has been whitewashed, it must be washed in vinegar to neutralize the alkali in the lime. If papered before and you wish the paper removed, sop with water and it will peel off.

If convenient provide a long board, wide as the paper, though a table or two will do. The paper must be measured, placed right side down on the board; then with a brush proceed to lay on the paste, not too thickly, but over every part, and be careful that the edges receive their share. When completed, double within three inches of the top, the paste sides being together; carry to the wall, mount your chair, and stick your three inches pasted paper on the wall at top. That holds it; now strip down the other, and see that it fits just right; if not, peel down, make right, then press to the wall from the centre right and left. Leave no air under, or when warm it will expand, bursting the paper.

Of course the paper must be matched; it will not do to measure by line unless the walls are perfectly plumb. Small figures make less waste, and make a small room look larger. Stripes make a low room higher, and if there are no figures between, or in the stripe to match, there is no waste, and no trouble in putting on. If a narrow border is the style, let it be bright, if the paper be neutral; but if that be bright, the border had better be dark and neutral.

If the paste be made too thick, the paper will be apt to crack and peel off; if too thin, it will saturate the paper too quickly and make it tender in putting on. A counter-duster (Brussels brush). is nice to brush the paper to the wall. White clean cloths will do, but it will not do to rub the paper with this; being damp, the paint or color rubs off the paper. The tables must be dried each time after pasting, for the same reason. Paste under paper must not freeze, neither dry too quickly. If whitewashing is done after papering, tack double strips of newspaper wider than the border all around the room.

HOUSEHOLD HINTS.

To Clean Paint. — Use but little water at a time; keep it warm and clean by changing often. A flannel cloth is better than cotton. Be careful of soap. Put but a little soap or skim-milk in the water; add soap to the cloth when needed. A sharp piece of soft wood is indispensable for the corners; the point will become like a paint brush. A saucer of sifted ashes, used where paint is badly smoked or fly-specks are thick, is better than soap; wipe last with clean wet towel, and don't spill a drop of water. Never put soap on glass unless it can be well rinsed, which can never be the case with windows; wash off dirt in clean warm water and dry; then with a paste of whiting and water, and with a little cloth, place a little in the centre of each pane. With another cloth rinse over the glass; next rub off with a dry cloth till the window shines like crystal.

A Brilliant Stucco Whitewash. — Take clean lumps of well-burnt lime, slack in hot water in a small tub, and cover it to keep in the steam. It should then be passed through a fine sieve in a fluid form to obtain the flower of lime. Add a quarter of a pound of whitening or burnt alum, two pounds of sugar, three pints of rice flour made into a thin and well-boiled paste, and one pound of glue dissolved over a slow fire. It is said to be more brilliant than plaster of Paris, and will last fifty years. It should be put on warm with a paint-brush.

A Breakfast Dish. — This is from a good foreign authority: "Bruise into a saucepan 4 oz. cheese, 2 oz. butter, a pint of water, with a little salt; boil gently, adding by degrees as much flour as would thicken it; let it dry on a stove until it is like thick new butter; then add either two or three eggs and a little cayenne."

The Arts.

HOW TO USE ANILINE DYES.

The following directions for the solution and application of the aniline dyes that are best suited for amateur or non-professional use have been carefully compiled and condensed from trustworthy authorities for the benefit of the readers of the Journal.

We will premise that *cleanliness*, which is important in the use of all dyes, is specially necessary in the case of the anilines, as a mere trace of foreign matter often makes a material difference in the color. Earthen or enamelled vessels are to be used in preference to iron. Woolen and silk goods before dyeing should be thoroughly washed in soap and water, and then rinsed in clean rain water. Cotton will not take the dye unless the fabric has been mordanted by treatment with sumac, or otherwise.

Red. *Magenta* (also called *roseine, fuchsine*, and *aniline red*) is readily soluble in alcohol, which, for use with these dyes, should be pure. To one pound of the crystals add 2½ gallons of the alcohol. Agitate frequently, and add 2½ gallons of hot water. Filter, if necessary.

For silk or wool, heat to about 170° F. water enough to cover, add a sufficient quantity of the dye, and immerse the goods for about half an hour, moving them about from time to time to prevent streaks. Half an ounce of the crystals will dye about ten pounds of wool.

For cotton, place the goods in a bath of sumac (one pound to ten pounds of cotton) for two hours; wring out, and proceed as with wool.

The dyes known as *cerise* and *safranine* resemble magenta, and are used in the same way; and the same may be said of *vesuvine*.

Crimson. This is best obtained by the use of *aniline yellow* and *magenta*. Apply the former as directed below, and then pass the fabric through a bath of magenta until the desired shade is produced. Or, by mixing the liquid yellow and magenta dyes in a bath of soap-suds almost any shade from magenta to orange may be got.

Scarlet. For amateurs the process given for crimson is the simplest. The yellow should predominate, or the bath may be slightly acidulated with sulphuric acid.

Yellow. Dissolve one pound of *aniline yellow* in two gallons of alcohol. With this liquid dye proceed as with magenta. A trace of sulphuric acid in the bath improves and brightens the color.

Phosphine is dissolved and used in the same way, except that a trace of carbonate of soda is substituted for the sulphuric acid; or a soap bath may be used.

Picric acid is employed for shades of lemon and canary that cannot be obtained with aniline yellow and phosphine. Dissolve one pound of the acid in *one* gallon of alcohol, and use as in the case of magenta.

Green. Picric acid may be used for this color. Pass the fabric through a bath containing sulphuric acid and alum, adding, after thorough immersion, a sufficient quantity of solution of picric acid and indigo extract.

The aniline dye known as *iodine green* or *night green* is not suited to non-professional use.

Blue. To dissolve *bleu de Lyon* and other aniline blues soluble in alcohol, use a stone jar fitted with a cover, through which a hole is made to admit a stick for stirring. Into this put one pound of the dye, five gallons of alcohol, and two ounces of sulphuric acid; apply the heat of a water bath and stir frequently. After allowing the mixture to cool, filter, and treat any undissolved residue with fresh alcohol until complete solution is effected. From five to eight gallons will be required.

In applying, the dye bath for wool should be rendered sour by sulphuric acid. Tin crystals may be used, in quantity about 2½ per cent. of the weight of the wool, to improve the vivacity of the shade. The bath should be brought to the boiling point. For silk, prepare a soap bath, add the color, and put in the goods. When dyed sufficiently, pass through a bath acidulated with sulphuric acid. Cotton is prepared as for magenta, and dyed in an acid bath as for wool.

The *water blue*, so called, is to be used by dissolving one pound in a mixture of one gallon of alcohol and four gallons of water. Apply as directed for *bleu de Lyon*.

In using *alkali blue* and *Nicholson's blue*, dissolve one pound of the dye in ten gallons of boiling water. Add this in small portions to the dye bath, which should be rendered alkaline by borax. The goods should be well worked about between adding the successive portions of color. Keep the temperature below 212° F. If the right proportion of borax is used, the goods will show but little color when taken from the bath. The color is developed by washing with water, and passing through a bath containing sulphuric acid.

Violet and Purple. *Parme, violet de fuchsine, Victoria violet*, and *amaranth* are dissolved as *bleu de Lyon*, omitting the sulphuric acid.

In applying, acidulate the bath with sulphuric acid, or use sulphate of soda: both these substances render the shade bluish. Dye at 212°. The color of the dyed fabric is improved by washing in soap and water, and then passing

through a bath containing sulphuric acid. According to Hirsch, cotton is treated as follows: "Prepare the goods for fuchsine, and turn them over a few times in a tepid solution of $2\frac{1}{4}$ ounces of crystallized perchloride of tin, for every ten pounds of goods. Remove the latter, add as much violet solution as the shade requires, dye for a quarter of an hour, wring well and dry. Washing in a solution of alum and starch will render the color more solid."

BROWN. Dissolve one pound of *aniline brown* in two gallons of alcohol. Add a sufficient quantity to the dye bath and immerse the fabric.

For the *Bismarck* shade, mix one pound of the Bismarck dye, five pounds of water, and twelve ounces of sulphuric acid. This paste dissolves readily in hot water, and may be used directly for dyeing. For wool, acidulate the bath with sulphuric acid, add sulphate of soda, immerse the fabric, and add the color by small portions, keeping the temperature below 212° F. Various shades may be produced by combining the color with indigo paste or picric acid.

Cotton must first be mordanted with sumac and acetate of alumina, and the bath must be below 100° F.

MEMORANDA IN THE ARTS.

ANOTHER SUBSTITUTE FOR WOOD ENGRAVING. — The *Polytechnisches Journal von Dingler* describes a new process called the "planotype." The design to be engraved is transferred to a block of lime-tree wood, which is then placed in a machine having somewhat the appearance of a carving machine (the shape of which varies considerably according to to the nature of the work), the graver being kept red-hot by a gas-jet. By means of this appliance the design is gradually burnt into the wood. Figures, or letters of reference, are impressed by means of punches. When the whole design has been burnt into the wood a cast in type metal is taken direct from the block; without any further preparation the cast may be used for printing from, like an ordinary stereotype plate. It is stated that the wood does not suffer in the slightest degree from the heat of the molten metal, and that even the finest details are faithfully reproduced. The process is carried out on a large scale, and is found to give most satisfactory results.

SOLUBLE GLASS FOR WASHING WOOLEN GOODS. — One part of neutral soluble glass is added to 40 parts of water at 45° R. (133° F.). In this solution the wool is immersed and worked about for a short time with the hand, and then rinsed in cold water. The results are said to be surprising, the wool emerging clean, white, soft, and without odor.

KRUPP'S STEEL WORKS IN PRUSSIA. — The famous establishment of Krupp, at Essen, has become gigantic in extent, as the following statistics will show. There are 514 smelting, roasting, and cement furnaces; 160 forges; 249 welding and heating furnaces; 245 coke furnaces; 120 furnaces of various other sorts; 340 turning lathes; 199 planing machines; 91 grinding machines; 65 grooving benches; 114 boring machines; 120 various other machines; 150 steam-boilers; 256 steam-engines having a total of 8,377 horse-power; 56 steam-hammers having an aggregate weight of 3,091 cwt. The number of work people is 7,100; and the amount of cast steel produced last year was 130,-000,000 lbs. Of the steam-engines, one is driven at 1000 horse-power, three at 800, one at 200, one at 180, three at 150, one at 120, three at 100, with 23 of a smaller power. Of the steam-hammers, one weighs 600 cwt., one 400 cwt., three 300 cwt., one 200 cwt., one 150 cwt., one 140 cwt., two 110 cwt., with forty-six smaller ones.

THE "CARBON PROCESS" OF PHOTOGRAPHIC PRINTING. — This term is applied to several different processes which are often compounded. They all depend on the property (described in the article on "Chromatized Gelatine" in the JOURNAL for October, 1870) which the chromates have of rendering gelatine insoluble when exposed to light. The "autotype" process makes the prints by the direct action of sunlight on a chromated gelatine tissue impregnated with coloring matter. The sunlight penetrating the negative, impresses those portions which represent the shadows, and the print thrown into tepid water permits the lights, which were protected by the dense parts of the negative, to be washed away. The results of this process are in all respects equal to silver prints, and are indestructible.

The "Woodbury type," or "photo-relief," is a mechanical process, in which the gelatine film is, after the action of the light, allowed to lie in cold water, which makes the film swell in those portions corresponding to the lights, producing an intaglio, from which a mould is made, which, being filled evenly with a gelatine ink, is transferred by a press to a paper, on which it dries, preserving all its lines and shades.

In the "Albert-type," the block (of ground glass) is coated with a similar film as in the other processes, which being wetted, swells and gives a printing surface, from which, as from a lithographic stone, many copies can be printed.

PRACTICAL RECIPES.

TO KEEP GUM ARABIC FROM MOULDING. — Solutions of gum arabic soon mould and sour, and finally lose their adhesive property. It is said that sulphate of quinine will prevent this, while it imparts no bad odor of its own. The addition of a solution of a few crystals of this salt to gum arabic will prevent the formation of mould quite as effectually as carbolic acid, and by analogy it is safe to suppose that the same salt could be used in writing ink, mucilage, and possibly glue.

TO RELACQUER BRASS. — The *English Mechanic* gives the following recipe: strong sulphuric acid, two parts; water, one part; red fuming nitrous acid, one part. These must be mixed in the open air, as the gas evolved on mixing the nitrous acid with the vitriol and water is of a suffocating character; this will pass off in the course of an hour or so, during which time the mixture may be occasionally stirred with a glass rod. The bright gilded effect produced on the brass by this mixture is so good that any one trying it will not return to the use of nitric acid. The subsequent washing, drying, and lacquering cannot be done too soon after the dipping, as the articles tarnish rapidly if kept unlacquered.

TO PROTECT WOOLEN FABRICS FROM MOTHS. — Dr. Vorwerk recommends the following mixtures for this purpose: (1) pure carbolic acid, 45.0 grms.; camphor and oil of rosemary each, 30 grms.; oil of cloves and aniline, each, 5 grms.; dissolve these substances in methylated spirit, 2 5 litres. (2) Pure carbolic acid, 20.0 grms.; camphor, oil of cloves, oil of lemon-rind (*Ol. citri cort.*), nitrobenzol, each, 10 grms.; aniline, 2.5 grms.; dissolve in methylated spirit, 1.5 litre. These fluids are applied to the fabrics and furs by the aid of the so-called spray-producers. The operation if properly done will only be required to be repeated twice or, at most, three times a year. Since these mixtures are inflammable, the operation with the spray-producers should be performed only by daylight. Neither goods nor colors are injured by exposure to the spray.

Agriculture.

ANALYSIS OF COMMERCIAL FERTILIZERS.

IN some remarks made at the Farmers' Meeting at Lakeside, in August last, we stated that we were engaged in making complete analysis of the different commercial fertilizers offered for sale in this market, and when the labors were completed the results would be published for the benefit of agriculture. The address given before the Massachusetts State Board of Agriculture at Fall River, in November, contains some of the results of these investigations, but as a large number of our readers do not have the opportunity of seeing the State Report in which the address will be published, we present the analysis of what is known as "Bradley's Superphosphate," and also those of the Upton fertilizers, which are four in number.

Specimens of the fertilizers subjected to analysis were procured of the manufacturers direct, from packages on sale in their warehouse, and therefore they are presumed to represent fairly the products of the makers as found in the market. The following is an accurate

ANALYSIS OF BRADLEY'S SUPERPHOSPHATE.

Water	9.76
Organic matter	41.71
Inorganic "	48.53
	100.00

It contained of

Silica	4.99
Soluble matter exclusive of water	23.95
Soluble phosphoric acid	7.03
Insoluble " "	12.44
Nitrogen	2.12
Potassa	0.00

We learn from the analysis that the superphosphate contains nearly ten per cent. of water, or about 200 lbs. in each ton, and also that it contains five per cent. of sand, or 100 lbs. in the ton; this gives 300 lbs. of worthless substances in each ton. It should be said, however, that it is difficult to thoroughly dry fertilizing substances, and ten per cent. is not a large amount of water; and it is possible that the sand may be an accidental ingredient.

The soluble phosphoric acid is not present in so large quantity as we hoped to find. It should contain at least double the quantity, to be of high standard; still, it holds much more than most of the superphosphates offered for sale. The insoluble phosphoric acid and nitrogen are present in fair quantity.

At present prices of bone char and mineral phosphates, we estimate the value of soluble phosphoric acid at 10 cts. per lb., the insoluble at 4 cts. The nitrogen we will take at Prof. Johnson's value, namely, 30 cts. per lb. The value of a ton of the superphosphate may be stated thus:

Soluble phosphoric acid	14.00
Insoluble " "	10.00
Nitrogen	12.00
	$36.00

This estimation of value varies considerably from that presented in our address, as since that was prepared we have purchased a large quantity of bone char for making our superphosphates for farm use, and we understand better the exact cost of materials. With the compounds called "superphosphates" found in the market this article certainly compares favorably.

The Upton Phosphates we will distinguish by the numbers 1, 2, 3, 4.

ANALYSIS OF UPTON'S PHOSPHATES.

	No. 1.	No. 2.	No. 3.	No. 4.
Water	12.97	8.21	25.86	21.25
Organic matter	37.70	44.96	21.69	37.88
Inorganic do.	49.33	46.83	52.45	40.87
	100.00	100.00	100.00	100.00

No one of these compounds contained any *soluble* phosphoric acid, and therefore they are not in any sense "superphosphates." Of *insoluble*, No. 1 contained 15.89; No. 2, 17.02; No. 3, 11.21; No. 4, 11.80. Of *nitrogen*, No. 1 held 1.59; No. 2, 1.55; the others were not examined for nitrogen. Only one of the specimens, No. 1, contained potash; the amount held was 2.38 per cent.

As regards these fertilizers, we have to say that while the percentage of water in some of them is very large, and while there is wanting soluble phosphoric acid, and in a part of them nitrogenous bodies, it should be remembered that the price asked for them corresponds in some measure with their value. They are sold at about one half the usual cost of superphosphates, and therefore some of the series are not dear at the price asked. It should also be stated that the gentlemen engaged in manufacturing them claim that their products are incidental to their business as glue makers, and that they sell them for what they are worth.

It is however a matter of regret that we cannot have in the market a standard "superphosphate," of high grade, of uniform quality, and one skilfully prepared. If any plan could be devised by which such an article could be easily and readily procured, it would be of great service to agriculture. Whilst it is true that the fertilizers sold in the Boston market are of better quality than those found in other cities, it is also true that some of them at least are considerably below a fair standard of excellence. We gave in our last number the results of two analyses of fish pomace. The quality of the articles analyzed was so excellent that, at the price asked for it by the manufacturer, we decided to purchase ten or twenty tons for our own use; accordingly we sent an agent to the party to examine his products, and make the purchase. The agent reported that he had no fish pomace for sale like the article sent for analysis, and that he also placed a higher price upon his wet, miserable stuff than he stated to us. Now in this we see the difficulties in the way of obtaining fertilizers of reliable character, and also we see the methods adopted to deceive purchasers. Chemists receive a good article for analysis, which in no respect represents that offered for sale. In this way great deceptions are carried on in many departments of trade.

ANALYSIS OF CORN COBS.

Considerable discussion has recently arisen in agricultural journals and at farmers' meetings upon the nutritive value of corn cobs when ground and fed to animals. It is a very common practice among farmers to grind the whole ears of corn, and feed the product to milch cows, working oxen, and often to horses. This plan we have adopted to a considerable extent at our own farm, but we have had some misgivings as to the utility or advisability of the practice. With the view of ascertaining as nearly as practicable the exact nutritive value of the cobs, we selected a nice ear of Lakeside corn from a bundle hanging in our counting-room, and removing the kernels, subjected the cob to analysis. It gave of —

Water	7.48
Crude fibre	30.95
Ash	1.16
Carbohydrates, fat, and albuminoids	60.41
	100.00

The amount of fat was not accurately determined, but it was proved to be more than one per cent. The amount of water is probably smaller than it would have been had the corn been taken directly from the grain house, instead of the warm room in which it had been hanging for some weeks. The results of the analysis prove that there is in corn cobs a considerable amount of fat-producing and flesh-forming constituents. In the sixty per cent. of carbohydrates, albuminoids, fat, etc., are found the elements which have nutritive value, and in order that we may obtain some idea of its comparative worth, let us contrast it with the dry straw of some grains. Wheat straw contains about 30 per cent. of carbohydrates, 2 per cent. of albuminoids, and $1\frac{1}{2}$ per cent. of fat; oat straw, 38 per cent. of the first named substances, $2\frac{1}{2}$ of the second, and 2 of the third; rye straw, 27 of the first, $1\frac{1}{2}$ of the second, and $1\frac{3}{10}$ of the third. It is shown that cobs have a higher value than wheat or rye straw, and they equal in nutritive constituents the best quality of oat straw. These results indicate the utility of feeding them to our animals, provided there are no objections of a strictly physical nature, or objections arising from bulk and difficulty of reducing the cob to a sufficiently fine powder. It is not probable that cob-meal can be perfectly digested unless comminution is carried to an extreme point, and therefore the finer the cobs are ground, the higher the value, and the less the liability of gastric disturbance. It is certain we do not give sufficient attention to the matter of grinding any of the grains fed to our animals. They should be ground *as fine as possible*, in order that they may be easy of digestion, and in order that the nutritive substances may be fully utilized. There is a positive loss in feeding out coarsely ground grains of any kind, and in grinding the cob with the corn, give special attention to the work of comminution. The corn in the ear should be thoroughly dry before it is carried to mill, and there will be less difficulty in reducing it to a fine powder.

GREEN CORN FODDER.

A correspondent of the *Country Gentleman*, evidently a sensible man and good observer, wrote as follows, during the last autumn: —

"Having three cows, and not having the grass for them, I concluded to soil them with sowed corn entirely. I commenced about the first of June, and have fed them bountifully ever since, with the aid of 18 or 20 heads of small loose cabbage apiece. Now for the result: The cow that would have given on grass 20 quarts per day, now gives only 12 quarts; No. 2, instead of 14 quarts per day, now only 8; No. 3, a heifer that did give in the past winter on dried stalks and feed 6 quarts per day, now only 2 quarts. The three cows are perceptibly decreasing in milk every day, and I fear by the time cool weather sets in, there will be more milk taken from the corn than from the cows. They have a shady, cool yard to run in during the day, and are stabled at night. I was always under the impression that sowed corn was a great supplier of milk. But I have come to the conclusion, so far as the cows show, that sowed corn fed alone and conti ually is not as valuable as we think. But gra and sowed corn fed together are all that we ca ask."

These results correspond with those obtaine at Lakeside farm, and which have been publishe in this journal. Green corn fodder raised unde the best possible conditions is not capable of su taining a flow of milk in cows, unless it is mixe with grass or hay; and the fodder raised care lessly from broadcast sowing is of but litt value as a milk-producing agent.

NEW ENGLAND AGRICULTURE.

A leading Philadelphia journal has remarke that "there is no use in denying that the who interior of New England has been pretty muc exhausted for agricultural purposes by its origin population." This is not true. Poor as is ou land, we can produce more bushels of whea corn, and the other cereal grains to the acr than any other section of the country. Ther is no difficulty in raising on fair land, proper cultivated, 75 or even 100 bushels of corn, a 30 or 40 bushels of wheat to the acre. We a now busy in blasting rocks, extracting stump and draining meadows; and soon, if mechanic and trade pursuits do not by the prospect of e traordinary profits entice away from our rugge soils all the young men, we will have Ne England's fields correspond in productivene with those of Old England. We have pluc here, and are not frightened by a granite boulde or a mossy swamp; we can tear in pieces t one, and dry and pulverize the other. New Eng land may yet become the garden of the country.

SEEDS AND CUTTINGS.

Watering Plants with Hot Water. — has lately been shown by careful experiment, th sickly potted plants, even some that have almo died out, can be greatly benefited, and sometime indeed, entirely restored to vigor, by applying war water to them instead of cold. In certain case oleanders which had never bloomed, or did so onl imperfectly, after being treated with luke-war water, increasing the temperature gradually fro 140° up to 170° F., produced the most magnifice luxuriance of bloom. Similar results occurred wit other plants, some of which had nearly withere away. In all these cases the application of wate heated to about 140° F., without any other precau tion, caused a new and flourishing growth.

Quick Raising of Radishes. — One of th Reports of our Department of Agriculture quote from the publications of the Acclimatization Societ of Palermo a statement that radishes may b obtained at any season, and very quickly, in th following manner: They will begin to germinate i about twenty-four hours, and are then to be set i a box filled with well-manured earth, and moistene from time to time with lukewarm water. In fiv or six days the radishes will attain the size of small onion. To grow radishes in winter, the bo is to be placed in a warm cellar, covered with top, and the earth moistened from day to day wit lukewarm water.

An Important Experiment in Sewage Irrigation. — At Leamington, England, sewage ir rigation works have just been constructed at a cos of £16,000 (or $80,000), and the Earl of Warwick has undertaken to dispose of the sewage for a term of thirty years. He devotes a farm of a thousand acres to the purpose, and pays £450 ($2,250) a year

towards the expense of pumping the sewage upon the estate. The town authorities pay the remainder of the expense connected with the pumping. The farm has been prepared according to the most approved plans, and in the most thorough manner. A model cattle-house has been built for the accommodation of several hundred head of stock, milch cows forming an important item in the herds. If not the largest sewage farm in England, it will be in all respects a model one, as the Earl will spare no labor or expense to test the principle of utilizing sewage for agricultural purposes. There is at present no little diversity of opinion as to the economy of this way of disposing of sewage, and also as to its effect upon the health of the stock and the wholesomeness of the vegetables raised, and this experiment will therefore attract much attention.

The Duchesse d'Angoulême Pear. — A French nobleman, observing his tenant about to destroy a fine, thrifty pear-tree, inquired the cause. He was told that it was a chance seedling, and had borne no fruit in twenty years. He had already cut its roots preparatory to the first stroke, but was ordered to let it remain. He did so, and in the following year it was loaded with superb fruit of an entirely unknown variety, which at once became celebrated. The root-pruning the gardener had given it worked like a charm. Not many years afterwards, when the Duchess of Angoulême was passing through Lyons, its inhabitants sent to her their hospitalities. Nine fair maidens presented the duchess with golden salvers, on which lay heaped this precious fruit, and begged her to bestow on it her name; and the pear now recognized as the crowning glory of all fruits was thenceforward known as the Duchesse d'Angoulême.

A Pretty Ornament. — Take a turnip, of convenient size, and scrape out the inside, leaving a thick wall all around. Fill the cavity with earth, and plant in it some clinging vine or morning-glory. Suspend the turnip with cords, and in a little time the vines twine around the strings, and the turnip, sprouting from below, will put forth leaves and stems that will turn upward and gracefully curl around the base.

The Sword turned to the Ploughshare. — The late General Ewell, of the Confederate Army, owned three thousand nine hundred acres of land in Maury County, Tennessee, one thousand two hundred of which were under cultivation. He had one thousand two hundred sheep, Southdowns, Cotswolds, and half-bloods, and four hundred head of cattle. He worked a dairy with fifty cows, averaging each a pound of butter per day.

Cider-Making in California. — We are not disposed to be envious of our friends on the Pacific shore, but it really is a comfort to know that some things are *not* possible in California. A local journal says: "Many experiments have been made to keep cider for winter use, as is done in the East. In one case an experienced cider manufacturer sent to England and procured a cider mill of the same kind as was used by his father, who manufactured cider for London. He set his mill in operation, put his apples through the same process, and produced a beverage, but it wasn't cider. A gentleman who tried it said whiskey was mild compared with that cider. California cider is excellent when new, but it won't keep. We have never known of an instance where it could be used after a month or two."

Superphosphates. — Since the article upon "Analysis of Commercial Fertilizers" was in print, we learn that Messrs. Upton, Shaw & Co. have greatly improved their works at Brighton, and design to enter upon the manufacture of "superphosphates" of a high standard of excellence. This is an improvement in the right direction.

Boston Journal of Chemistry.

BOSTON, MARCH 1, 1872.

PERSONAL ABUSE IN SCIENTIFIC DISCUSSION.

It is indeed a matter of profound regret, that gentlemen engaged in scientific research cannot pursue their noble and most important labors without stopping to indulge in the degrading, vulgar business of personal abuse. Whilst we ought not perhaps to expect perfection of character or temper among students and investigators, yet education and high mental culture ought to influence a man's nature, and lead him to manifest at all times courtesy, generosity, and a kindly feeling towards his associates and co-laborers. But doctors quarrel, and so do lawyers, and even clergymen; we wish it were otherwise among men of science, but alas! it is not. Jealousy, pride of opinion, arrogance, conceit, all these have their influence in engendering strife, and keeping up animosities which ought not to exist.

Just now, scientific investigators in England are "all by the ears" upon the matter of the "pyschic force," or "spiritual manifestations," and Dr. Crookes the distinguished chemist, Mr. Huggins the astronomer, Mr. Varley the electrician, Lord Lindsay, and others, are assailed in the most violent manner in journals and reviews for their investigations of the phenomena. It would be difficult to find in the literature of any science, art, profession, or business, more spiteful, vindictive, personal attacks than are made upon these gentlemen in several of the last numbers of the *London Quarterly* and *Popular Science Review*.

Dr. Crookes in particular is made the target for a volley of abuse which would quite intimidate any man of less ability, or one less secure in his position. The assailant in the *Popular Science Review* is a Mr. J. P. Earwaker, of Merton College, Oxford, a gentleman whom we never heard of before. His name "Earwaker" suggests noise and clamor, and he is true to his patronym. The article in the *London Quarterly* was written we suppose by Dr. Wm. Carpenter, a man who is well known among scientists here, as well as abroad. Dr. Crookes condescends to reply to this reviewer, and has published a pamphlet, a copy of which has been sent to us. If any of our readers wish to see as fine a specimen of caustic criticism as has ever appeared, let them procure this pamphlet. If the reply does not take the arrogance and conceit out of Dr. Carpenter, he has a tougher cuticular covering than most men. There really is no occasion for this abuse of Dr. Crookes and the other gentlemen associated with him. If any one dissents from his conclusions, why not express it in a dignified and courteous manner? The position of these assailants is highly dishonorable, as they undertake to criticise and overthrow experimental results by personal detraction. They act the part of empirics and charlatans by meeting systematic, careful observations and scientific tests with cheap dogmatism and spiteful innuendoes. But Dr. Crookes is fully able to take care of himself, and in his defence he does not find it necessary to imitate the bad temper of his assailants.

We turn from this controversy among scientific men to another which is nearer home, and which we are happy to say is conducted in a better spirit. Prof. Hunt, the eminent chemist and geologist, in his address before the American Association at Indianapolis, last summer, made some observations or statements respecting rock crystals which Prof. Dana of Yale regards as erroneous. Prof. Hunt also, in a mild way, attacked Prof. Dana's views upon some points in crystallography, and when any one attempts to criticise so able and careful an observer as Prof. Dana, he must look well to his weapons of defence, for his antagonist is a giant. We well remember his tilt with Prof. Horsford of Cambridge, a dozen years ago, upon the theory of the formation of coral reefs, and the source of carbonic acid in the waters of the Florida Keys. Although not professing to be a chemist, he proved that he was a formidable antagonist when chemical points were under discussion. Prof. Dana's reply to Hunt appears in the last number of the *American Journal of Science and Arts*, and doubtless it will provoke further controversy. The subject is one which would hardly interest our readers, and therefore we will not bring it before them. The able journal to which we have alluded can be consulted by those who wish to know more of the matter.

ANALYSIS OF SWEET CORN.

We made in our laboratory, last autumn, a careful analysis of sweet corn, the ordinary eight-rowed variety, as found for sale in Faneuil Hall Market. The specimen was fresh, and the ear and kernels were as perfectly developed as any brought in from the country. The analysis gave of—

Water	72.92
Fat	1.60
Sugar and Gum	7.51
Starch	13.54
Nitrogenized substances	2.73

As the object was to ascertain the nutritive value of the corn, we present only those substances. It will be seen that the corn contained of fat, sugar, gum, starch, and nitrogenized bodies, more

than 25 per cent. These principles give to green corn a high value, and whether it is fed to animals, or placed upon our dinner tables, it has good claims to be regarded as among the important food substances. That we may understand what important changes are wrought in the grain by the process of ripening, we present below the analysis of dry corn, as given in one of Prof. Johnson's books: —

Water	12.00
Fat	4.06
Sugar and Gum	2.07
Starch	54.04
Nitrogenized substances	8.08

Here we notice the great increase of fat, starch, and nitrogenous bodies, which give to ripe corn a still higher value, and render it a more concentrated form of food.

With the view of ascertaining the effects upon green corn of the process of cooking, and also the effects of keeping it in hermetically sealed cans, we made analysis of two specimens found in the market, which were alleged to be preserved under different methods. The two brands are known as Winslow's and Durant's, and both corresponded in physical appearance when the cans were opened. The Winslow corn had, however, a stale, unpleasant odor, whilst the Durant specimen was as fresh as if it came direct from the dinner pot to the table. The variation in the methods of treatment is wholly immaterial, as regards good results, and the observed differences in the specimens are due to the age of the corn, and the cleanliness and care exercised in boiling and canning. The analysis of the two specimens gave the following results:

	Winslow's.	Durant's.
Water	65.31	63.88
Fat	2.06	1.87
Sugar and Gum	11.03	15.54
Starch	16.26	13.88
Nitrogenized substances	3.59	3.51

The water in the cooked corn is less than in the uncooked, as a portion of the natural juice is removed, and also the amount of fat, sugar and gum, and nitrogenized bodies is larger. This may be due in part to changes produced in cooking, and in part to differences in the corn existing prior to subjecting the specimens to this process.

We learn from the results of these labors that sweet corn undergoes comparatively few changes when cooked, and kept many months, if air is excluded. If nice, fresh corn is selected, carefully cooked, and placed in clean glass vessels hermetically sealed, it affords a nutritious and palatable dish in the winter months, and every family should secure a supply.

A VETERAN APOTHECARY.

One of the best known and most highly respected of our citizens is Dr. Hollis, the veteran apothecary on Union Street. Dr. Hollis has occupied the store where he now is for *forty-eight years*, and during this long period has not been absent from his post for ten consecutive days. There have been many years when he has not been absent a single day, and notwithstanding his age, which is seventy, he is still to be found behind his counter, displaying the same care and skill in compounding and dispensing medicines which he has manifested during half a century. He is a thoroughly educated apothecary of the old school, and as a chemist has a deserved reputation. We well remember the excitement produced in scientific circles, and among the people generally, when the first intelligence of Schönbein's discovery of gun-cotton reached this country. The method of manufacture was not fully disclosed, and every chemist went to work endeavoring to produce the agent. Dr. Hollis was the first to succeed, and his store was for a time filled with curious people, anxious to see the wonderful explosive.

It is a pleasure to look in upon Dr. Hollis and observe the neatness, care, and skill everywhere displayed. Here are no plate glass windows, marble counters, and flashy bottles and drawers, to dazzle and bewilder. Everything in the way of fixtures and appointments remains about the same as when the young apothecary first took the store in the early part of the present century. There is noticed a wholesome and agreeable odor of medicines, untainted by the flavor of cigars, confectionery, soaps, or colognes. No miniature marble cathedral stands upon his counter, from which to draw "soda," and a host of strange mixtures called mineral waters.

We somehow have a feeling that better medicinal agents are obtainable in such pharmacies, and are inclined to pass by the showy corner "drug-store," and trust to old-fashioned bottles and drawers for holding, and old-fashioned scales for weighing the remedies we require. But few of these establishments remain. Dr. Webb, of Salem, Dr. Gale, of Portland, and others in the cities and towns of New England, held to the "old ways" as long as they lived, but they have gone, and soon not a single example of the old style of keeping and dispensing medicines will be left.

We hope our venerable fellow-citizen will live, not only to fully complete the half century of business in his store, but for many years to enjoy the fruits of his honest industry and professional skill.

EXPERTS AT FAULT.

The fact that "doctors disagree" has passed into a proverb, and the conflicting testimony given in courts of law by scientific experts is a matter of common remark. The Wharton murder trial has recently furnished a striking instance of the kind, and the New York *Evening Post* mentions another connected with a case recently tried in the Superior Court of that city. The matter in dispute was the right to a "trade-mark" for a certain brand of mustard, and Prof. Doremus (whose name often appears on published "certificates" as an analytical chemist) had testified that mustard contains more than eleven per cent. of starch. The *Post* gives the following account of the subsequent proceedings: —

"Two other analytical chemists, one of them Professor Chandler, of Columbia College, alleged that mustard contained no starch. The evidence was in this conflicting condition when both parties rested, and the case was adjourned until the next morning for argument. In the mean time Professor Doremus applied to the counsel of the defendant to move to so far open the case as to allow him to vindicate by actual experiment in open court the correctness of his statement as to the existence of starch in mustard. The motion was made and granted; and at the appointed time the court-room presented the appearance of a chemical laboratory.

"The Professor, with his assistant, prepared mustard for experiment in open court by pounding the seed in a mortar. He placed the crushed seed in distilled water and boiled the mixture over a spirit lamp. He then threw some of the solution on sheets of filtering paper, applied his chemical test, and exhibited to the court on the paper the characteristic blue iodide of starch. The experiment was varied in many ways with the same result, and at the end of the testimony many sheets of paper were thus colored. The demonstration seemed perfect. On Professor Chandler being called to the stand he made experiments which in his view demonstrated that starch did not exist in mustard, and stated that he was not satisfied with the experiments that had been made by the defendant's witness.

"'Why,' said the defendant's counsel, 'are you not satisfied with the reaction for starch exhibited by Dr. Doremus on the dozen or more sheets of filtering paper?'

"'I am not certain, to begin with,' said Professor Chandler, 'that the paper would not have produced that reaction without the mustard.' Whereupon the counsel handed to the witness some of the clean paper and asked him to apply the test to it himself. He did so, and the result was a deep blue, thus showing the illusory nature of the prior tests, and that the experiment was entirely worthless as proof that starch was contained in mustard."

EDITORIAL NOTES.

War Statistics. — The *Elberfeld Gazette* publishes some curious statistics of the comparative deadliness of the different weapons used in the Franco-German war. According to them, of 3,453 Germans wounded before Metz, no fewer than 95.5 per cent. were struck by Chassepôt balls; 2.7 per cent. only were wounded by projectiles from heavy guns, and there were only 0.8 per cent. of wounds from cold steel. As to the French wounded, it is calculated that as high a proportion as 25 per cent. were wounded by artillery projectiles, and about 70 per cent. by the fire of the needle-gun. No fewer than 25,000 Frenchmen in all were struck by the projectiles of the German artillery. This gives an average of one effective shot in every three fired from the German batteries, a result which appears hardly credible. The losses in the different branches of the German army are estimated as follows by the *Gazette:* Of every 100 men put *hors du combat*, 90 per cent. were in the infantry, 5 per cent. were in the cavalry, and only 3 per cent. belonged to the artillery. The total number of cartridges fired by the Germans in the late war is said to have been 25,000,000, or about 30 per man. The war having lasted — for fighting purposes — just six months, this gives only an average of five cartridges per man per month for the whole army. Taking the total number of French killed and wounded at 100,000, this would give an average of 250 cartridges fired to each man struck.

How to Distinguish Linen, Cotton, Silk, etc. — If a thread of linen or cotton yarn be held by an end in each hand, and then slowly drawn out until it breaks, without receiving any sudden jerk, it will be found that the cotton is more unequally broken, its extremities distended, frizzed, branched, and twisted. Linen, on the other hand, breaks off more cleanly, its ends forming short tufts, of which the section is perpendicular to the axis, and whose filaments are straight. The distinction is readily recognized, and once seen cannot be forgotten. Some investigations on the separation of silk from other fibres were made by Mr. John Spiller, in England, not long ago; and in the course of his experiments he found that hydrochloric acid was an energetic solvent of silk, although it left wool and cotton unacted on, at least for a lengthened period. The practical bearing of this discovery was exemplified by the immersion of several so-called pure silk ribbons and other fabrics in the acid, when the

silk was dissolved away, leaving the threads of the adulterating material intact. A lady, previous to purchasing an alleged silk material, may thus be able to satisfy herself that the fabric is really what it is professed to be, by obtaining a small sample of it and immersing it for a few seconds in hydrochloric acid; or better, by dropping a little of the acid on the centre of the sample, when if it be pure silk a hole will be made, but if impure, the threads left will immediately indicate the nature and extent of the adulteration.

Muscular Christianity. — The Archbishop of York has been proving his claim to be considered a muscular Christian. A correspondent of the *Manchester Examiner* says that "a few evenings ago a man, evidently not suffering from the effects of total abstinence, was found on the road between York and Bishopsthorpe in charge of a horse and cart laden with meat, which had become entangled in a heap of stones. His cries brought to his assistance another man who happened to be passing near the spot, but the efforts of both were insufficient to extricate the horse and cart from its unpleasant position; and thus matters might have remained until now but for the timely arrival of the Archbishop of York, who, at this juncture, with a party of clerical friends, drove up in his carriage. His grace, observing the state of affairs, at once ordered his coachmen to stop, and he and his friends descended into the road. The Archbishop then put his shoulder to the wheel, and with a few vigorous pushes succeeded in setting the imprisoned horse and its load once more at liberty. Nor did his good deeds end here, for, heedless of the mud-stains which he had contracted during his exertions, he administered a few words of salutary advice to the erring wagoner, and then, reëntering his carriage, proceeded on his journey, leaving a most pleasant impression behind him."

Scientific Aids to Swimming. — A French inventor has patented an apparatus for swimmers, but we think that any frog might bring an action against the man for infringement of a device secured to the batrachians by endowment of nature. For the hands he has a large membranous fin, which is held in its place by loops passing over the fingers and a strap around the wrist. The surface presented to the water by these fins is so large as to add greatly to the effectiveness of the strokes of the arm, but not so large as to exhaust the muscular power. Their effect is to reduce very much the effort required to swim without them. But the greatest ingenuity is displayed in the form and fitness of the fins for the legs, which are attached to the ankles, and are so formed that they act upon the water, both in the movement of bringing the legs together and throwing them back. They act so finely in "treading water," as swimmers call it, that one can really walk, if not on the water, at least in it. The difference between swimming with this apparatus and without it, is very much like the difference between rowing a boat with the handle and the blade of an oar. The old swimmer has no trouble in using the fins at first trial, and is surprised to find with what strength he can swim without exhaustion. He easily swims twice as fast with the apparatus as without it, and he can sustain himself for hours upon the water, or swim miles with it.

Carrier-Pigeons in Belgium. — An English journal says: "Pigeon-flying is quite as popular in Belgium as horse-racing is in England, with the very great difference, and credit to them, that, at present, their hobby or passion is not made an excuse for betting and debauchery. The Pigeon Societies, or as they are termed in Brussels, 'Sociétés Colombophiles,' and in Courtrai, 'Société Peristeraphile,' are subscribed to, and supported by, every grade of society, from the worthy king and princes downwards." The breeding and training of the birds is carried on in the most systematic manner, and several times during the year matches are instituted for various distances, from one to 900 miles, for birds of different ages, and which have been trained up to certain journeys. At many of the railway stations in Belgium one may see, almost every week, large numbers of these birds, in charge of a single man, who has his instructions for letting off the occupants at certain stations, given distances from home. Sometimes these men may be seen with as many as a hundred baskets, each stamped and labelled by their respective owners, or by the societies of which their owners are members.

ATOMS.

Dr. Calvert has found that alkaline carbonates have the same property as the caustic alkalies, of preventing the oxidation of iron immersed in their solutions; a plate of iron having been thus kept free from oxidation for two years in a solution of carbonate of soda, and also in sea-water to which soda or potash had been added. — A bed of phosphates, somewhat like the deposits near Charleston, S. C., has been discovered in Russia. — The spectroscope has been employed to measure the rotation of the sun, and the results approximate closely to those obtained by observations upon the spots. — The *English Mechanic* says that the degree of Ph. D., which it wickedly translates as "Doctor of Phudge," is easily bought at the cost of a few pounds. — Chloroform often removes grease or paint from clothing when benzine or bisulphide of carbon fails to do it. — Iron vessels of a thousand tons are now built which draw only eighteen inches of water, and a company has been formed in New Orleans to provide such vessels for the transportation of the products of the Mississippi Valley to that city. — "Crito! I owe a cock to Esculapius; will you remember to pay the debt?" were the last words of Socrates; and, as some one remarks, only a great and a truly good man could think of his doctor's bill at such a time. — Thin milk of lime (if warm, it will act more promptly) can be used for cleansing glass vessels in which petroleum has been kept, as it forms an emulsion with that liquid; and the addition of a little chloride of lime to a second washing with the milk of lime removes even the smell completely. — The Viceroy of Egypt has begun to build a railroad, six hundred miles long, between Lower and Upper Egypt; so that Livingstone may yet be able to come home from Central Africa by rail. — In a school where the pupil is required to write a sentence containing the words given out to be spelled, the word "panegyric" drew forth the following: "A few drops of panegyric, given on a large lump of sugar, is often best with an infant with the stomach-ache." — The skeleton of the whale recently on exhibition in Boston has been "mounted" in the rooms of the Society of Natural History, and is considered one of the most remarkable specimens in America. — Professor Agassiz writes home that he has discovered the nest of a fish in the *sargassum* or seaweed of the Gulf Stream, and has hatched out a dozen or more young fishes from the eggs found therein. — Among the ruins of Chicago is a "clinker" resulting from the melting down of about nine thousand stoves mixed up with enormous quantities of brick and stone, and all efforts to break it up have thus far been in vain. — It is proposed to place a painted window in the parish church at Berkeley (Eng.) in honor of Dr. Edward Jenner, the discoverer of vaccination, who was born in that town and was buried in the chancel of the church; the subject of the window, which is to cost £500, being "Christ Healing the Sick." — The two principal companies engaged in beet sugar culture in California, will extend the field of their operations to one thousand acres during the present year. — An electro-magnetic engine, to be used for driving a plugging tool in the operation of filling teeth, was exhibited at a recent meeting of the Franklin Institute in Philadelphia. — There is no end to the jokes on Greeley's agricultural advice that appear in the papers, one of the latest being the statement that he says that "The best way to raise early popcorn is to start it *now;* put the corn (any kind will do) into a corn-popper, and suspend in the sun over a pan of water till the shoots grow out between the wires; then in the spring set it out in pots or beds, and before June the popped corn will be hanging in little paper bags all over the branches." — It has been suggested that printer's ink is a cheap remedy against the ravages of the canker-worm; whereupon some one remarks that the best way to use it is in the shape of good agricultural literature. — "Diamonds" have been discovered in Arizona; but their estimated worth is from forty to sixty cents a bushel. — As an evidence of the progress of civilization in Japan, it is stated that many fires have lately occurred in Yedo, "caused by the careless use of kerosene." — M. Sezille has described, before the Agricultural Society of France, a method of preparing wheat, by which he claims that out of one hundred pounds of wheat twenty pounds more of bread are obtained than by the ordinary method of grinding and bolting representing an increase of about 25 per cent. of the nutritive value. — Dr. Crookes's pamphlet in reply to the *Quarterly Review* and other critics, to which we have referred elsewhere, is published by Longmans, Green, & Co., Paternoster Row, London, and the price is one shilling (twenty-five cents). — The deepest mining shaft in North America is said to be one at the Gould and Curry mine, in Nevada, which has gone down perpendicularly fifteen hundred feet. — A plant known as the *Andromeda Leschenaultii*, growing in India, has been found to yield carbolic acid of a very pure quality, but the cost of its extraction is such that the discovery, though interesting as a botanical and chemical fact, is of no practical or commercial importance. — *Harper's Weekly* uses fifteen tons of paper every week, and the average cost of engraving for each number is $600, or $30,000 a year, with as much more for drawing the pictures on the wood, exclusive of the sums paid to artists for the designs. — In consequence of the numerous frauds committed by forged checks, some of the Vienna bankers have adopted the custom of sending, with their letter of advice, a photograph of the person in whose favor the credit has been issued, and to stop payment when the person who presents himself does not resemble the picture. — The committee appointed to investigate the gun-cotton explosion at Stowmarket, England, have come to the conclusion that the *manufacture* of gun-cotton is perfectly safe, all the operations being conducted while the material is in a damp and consequently non-explosive condition; but that the drying should be carried on at a distance from other buildings, and that the store-houses of the dried product should be similarly isolated. — Prof. Henry, of the Smithsonian Institution, commenting upon the popular belief that the removal of forests tends to diminish the average rain-fall, stated that the observations of the Institution, which extend over a period of twenty years, have as yet failed to establish a theory of this kind, and that it must therefore be regarded as a gratuitous hypothesis, unsubstantiated by fact.

LITERARY NOTES.

The *Commonwealth* (Boston) of February 10th, has the following notice of Mr. Rolfe's edition of Shakespeare's *King Henry the Eighth*, just published by the Harpers: "It is a tasteful 16mo of 210 pages, and is prepared on the same plan as the author's 'Merchant of Venice,' and 'The Tempest.' The text is the result of a careful collation of the folio of 1623 with all the modern editions that have any critical value. A valuable introduction gives us the history of the play, a history

of the sources of the play, and sundry critical comments on it. Then follow the play in delightfully clear type, and the notes. We have been struck with the patience and erudition manifest in this edition of this play, and feel that every lover of Shakespeare who may chance to see the volume will heartily thank the author therefor. As a text-book for schools and reading-clubs, nothing can be more complete and satisfactory. It gives all the incidental information needed by the references of the text, and cites the best critics thereon to establish the true meaning of the great dramatist. These, with its numerous finely drawn illustrations, make it at once a beautiful and comprehensive edition of this great work."

The Harpers have also issued Vol. I. of Tyerman's *Life and Times of the Rev. John Wesley* (to be completed in three volumes); *The Land of Desolation*, a personal narrative of observation and exploration in Greenland, by Dr. Hayes; and Smiles's *Character*, which seems to us a worthy sequel or companion to his "Self-Help."

Messrs. Hurd & Houghton have recently published two little collections of poetry of more than average excellence, — Mrs. Celia Thaxter's *Poems*, mainly lyrics of the New England sea-shore, as characteristic in their way as Whittier's "Ballads" — and *Landmarks and other Poems*, by John James Piatt, whose verses bear as unmistakably the local coloring of the West as hers do of the East.

Dr. Ely Van de Warker, of Syracuse, N. Y., has sent us his valuable monograph on *Criminal Abortion*, published by Mr. James Campbell of this city. It is a very sensible and thorough treatise on this important subject, and should be read by the profession everywhere.

We have also received from Dr. B. F. Dawson, of New York, his paper on *Vascular Nævi*, reprinted from the November number of the "American Journal of Obstetrics." It is an important contribution to the literature of this branch of surgery, and one for which the author deserves the thanks of his professional brethren.

Medicine.

AN ALLEGED NEW DISCOVERY.

Dr. J. R. Chadwick, now at Vienna, in a letter to the editor of the *Boston Medical and Surgical Journal*, describes a new discovery made by Dr. Lostorfer in reference to the blood. He claims to have discovered in the blood of syphilitic patients morbid or germinal growths, which he denominates "syphilitic corpuscles." According to Dr. Chadwick, the whole "medical world" of Vienna is in a state of excitement over this alleged new discovery. Prof. Stricker and the renowned Prof. Hebra have become converts to the new truths revealed by Dr. Lostorfer's microscope, and the doctor has been examining blood drawn from Prof. Stricker's veins. This he pronounces "full of filth," or it "contains more filth than that of any other living man." This statement, which sounds to us very much like that of an empiric, is assented to by Prof. Hebra, and he has commenced tapping his patients in the hospital, endeavoring to find a specimen of blood as "full of filth" as that of Prof. Stricker. He is reported not to have succeeded in this, and therefore Prof. Stricker, so far as investigations have gone, stands at the head for "bad blood." The discovery of "syphilitic corpuscles" in the blood of those affected with this disease may be new in Germany, but it is not in this country. More than two years ago, Dr. Graves, of the Marine Hospital, Chelsea, placed the syphilitic wards of that hospital at the disposal of Dr. Cutter, of Woburn, and numerous microscopical examinations were made, in which the morbid growths were distinctly seen in the blood of the patients. We were present, and with a Tolles $\frac{1}{5}$ objective used in connection with Cutter's clinical microscope, the blood of some of the patients was seen to be charged with the "algoid vegetations," as described by Dr. Salisbury of Cleveland.

To Dr. Salisbury belongs the honor of first pointing out these strange morbid growths in the blood, and his researches with the microscope have not been so highly appreciated as they ought to be in this country. He is a most indefatigable student, and in the course of his investigations some discoveries have been made of the highest importance in medicine. We think this excitement in Vienna, described by Dr. Chadwick, will serve to turn the attention of medical gentlemen towards the researches of Dr. Salisbury, and that due credit and honor will be awarded him.

THE CINCHONA TREE IN INDIA.

It is pretty certain that the attempts of the British Government to cultivate the cinchona tree in India will prove successful; indeed, from recent accounts it would appear that the tree is flourishing in that country, and that it not only yields its normal proportion of alkaloids, but in some species at least, there is a large increase.

At one time it was feared that the length of time needed for the trees to renew their coating of bark, after this had been partially removed, would have constituted a serious obstacle to the remunerative culture of cinchonas in India. This difficulty has been removed by accelerating the production of new bark by the simple application of moss kept continually damp. New bark forms under such circumstances rapidly.

What renders this process of renewal the more important is the fact that the quantity of alkaloid found in the bark of the third time of renewal is not only larger, but is in a state that is more easily purified, and better fitted for the extraction of quinine, than the bark in its normal condition. This circumstance, as well as the comparative analyses of various portions of the trees, seem to point to the bark as the seat of the formation of the alkaloid.

With regard to the mode in which the alkaloid is formed in the bark, the general result of experiments goes to show that there is originally in the plant but a single substance, which assumes different characters according as it is exposed to or excluded from the action of light. There are, as is well known, two opposite modes of respiration in plants: one is carried on in the light and in the exposed parts of plants, and results in the elimination of oxygen and the fixation of carbon; the other manifested chiefly, but not entirely, in the night, and in those portions of the plant not exposed to the light. Experiments have shown that by varying the conditions of growth it is possible to change at discretion the production of chlorophyll into the elaboration of coloring matter similar to that of the roots.

It is surmised, with great probability, that the increased production of alkaloids in bark treated by the above process is due to a similar replacement of one form of respiration by the other; in other words, by making the formative energy of the plant manifest itself in the production of alkaloids rather than in that of chlorophyll.

As to the particular part of the bark which is the chief seat of the formation and deposit of the coveted ingredient, it is supposed that it is in the cellular portion of the bark, not in the wood or bast-cells, that the alkaloid exists chiefly — a conclusion that is so wholly reasonable, and in accordance with analogy, that it seems remarkable that the contrary view could have been held.

MEDICINE AND CHEMISTRY.

Prof. Silliman delivered the introductor lecture to the medical class in Yale College i September, and we have been much interested i reading the published copy he was so kind as t send us. The topic of the lecture, "A Centur of Medicine and Chemistry," is one which it wa found impossible to treat fully in so brief tim and consequently he devotes the hour to the di cussion of anæsthesia and the history and chem istry of anæsthetics. It is decidedly the bes *résumé* of the subject which has appeared, an in its preparation the most thorough research i indicated. We design to make some extract from this lecture at a future time, but at preser have room only for the closing sentences: —

"In reviewing the field of modern chemistry organic and inorganic, in view of its physiologica and therapeutic relations, it is simply impossible t form the slightest rational conjecture of the proba bilities which are in store for the healing art in th near future. The ground gone over in this lectur may appear extensive, but it is only a corner of th vast domain, in every part of which mines of ric ore are waiting only the exploratory work of th physiological chemist to reward humanity with ne blessings, even more fruitful of good, perhaps, tha those the history of which we have so rapidl sketched.

"The time was when chemistry existed only i the hands of the so-called *Iatro-Chemists*, or Doctor Chemists. This name has often been used as term of reproach, but the labors of such doctor chemists as those whose researches we have bee considering, are fast teaching us that great discover ies in therapeutics and physiology are to be mad only by renewing the bond which make the Physi cian and Chemist one; and may we not truly sa that if every chemist is not a doctor, every doctor must be a chemist, if he would march in the van of the great army of those who by searching would find out the truth, and by its skilful and scientific use bless mankind, and crown their lives with happiness and honor."

IODIDE OF CALCIUM.

Dr. Goodman (*Canada Lancet*), at a recent meeting of the Medical Society for Mutual Improvement, spoke in favor of the use of iodide of calcium as a remarkably mild and efficient alterative; it appeared to him to be more easily assimilated in disordered states of the stomach than any other iodide; he had used it lately with marked effect in diseases of the stomach and bowels in the strumous diathesis. — *Georgia Med. Comp.*

Remarks. — The present very high price of iodide of potassium will undoubtedly serve to direct the attention of physicians to *iodide of calcium*, or "*iodide of lime*," as a valuable and cheap alterative resolvent, and tonic. It has been proved capable of taking the place of the other iodine combinations, and it has advantages possessed by no one of them. These advantages may be enumerated as follows: —

1. In the smallness of the dose, and the minute state of its atomic division.
2. In its ready combination with the blood and tissues, manifested by its alterative effects.
3. In not passing off rapidly by the kidneys.
4. In not producing gastro-enteritic and vesical irritation.
5. In being cheaper than the other iodides.
6. In being compatible with most remedies, and admitting of a variety of combinations in extemporaneous prescriptions.

The chemical relations of the iodine are with oxide of calcium, and not wholly with the metallic base. It is probable that the iodine and oxide of calcium exist chemically in a form similar to that which exists between chlorine and lime in the so-called *chloride of lime*, hence we prefer to call it "iodide of lime." The new bodies formed by the combination are iodide of calcium and iodate of lime:

$$6CaO+6I=5CaI+CaO,IO_5.$$

The chemical affinities of the salt are so feeble that it must be kept securely in glass-stoppered vials. It has the disadvantage of requiring to be placed in *solution* before being administered, as the *powder must not be given in dry form.* This disadvantage is, however, of but small account, since the solution is readily made with warm water. The solution is *permanent, colorless,* and almost *tasteless.*

The best and most convenient form for physicians' employment, by prescription and otherwise, is that of the

SYRUPUS CALCIS IODIDI.

This is a concentrated aqueous solution, prepared with sugar, perfectly clear, of very pleasant taste, and it will keep any length of time unaltered. Each fluid ounce holds the active principles of fifteen grains of the iodide of lime, and the dose is a teaspoonful to adults as often as may be required.

Messrs. J. R. Nichols & Co., chemists, of this city, supply the *iodide of lime* in one ounce and one pound packages, and also the *Syrupus Calcis Iodidi,* in one and seven pound packages. The price of the dry salt is 50 cents per ounce; of the syrup, 85 cents per pound.

RICHARD S. SPOFFORD, M. D., died at his residence in this city on Friday morning a little after midnight, in the eighty-fifth year of his age; he having been born on the 24th of May, 1787. When a great statesman or warrior dies the sensation is proportioned to the prominence of his career, but the events of the life of a physician and scholar, like Dr. Spofford, are not such as to bring him prominently before the people. His life was one of study and of beneficence, and his loss will be felt more as that of a personal friend by multitudes in this city and vicinity, than as that of a public man.

Remarks. — The above announcement of the death of a distinguished physician and kind friend appears in the *Newburyport Herald* of January 23d. Dr. Spofford attained the great age of 85 years, and consequently was one of the oldest members of the Massachusetts Medical Society at the time of his death. His father was one of the founders of the society, and Dr. Perkins of Newburyport, his student in medicine in 1825, has recently served as president of the society. Dr. Spofford engaged in the practice of medicine in Newburyport in 1816, and it is quite true, as stated in the *Herald*, that during the half century that Dr. Spofford practised here the people have had an opportunity of learning something of his character. He was generous and unselfish, and where he was called by distress, he went to its relief without asking whence the fee was to come. Indeed, his benevolence leaned to the side of a fault in his character. He was a kind friend, witty and entertaining in conversation, his memory stored with extensive reading of ancient and modern literature and science; he was equally ready with a quotation from Homer or a discussion of Huxley and Tyndall and Darwin; the original text of the Hebrew Scriptures, or a problem in the higher mathematics. The doctor had a wonderful quickness of insight. Those great eyes of his saw everything within the range of their vision, and saw through it at once. Accordingly he was great in the diagnosis of disease; his astonishing quickness of apprehension and perception was of great use to him in this part of his profession, and gave him a reputation in it that would have made him a rich man if he had been of such a disposition as would have led him to gather riches.

This venerable physician was a firm friend of the JOURNAL OF CHEMISTRY, having been one of its patrons from the start. Every number was read as soon as received, and we are indebted to him for many kind words spoken in its behalf. The old landmarks in the field of medicine are passing away, and we must make the most of those that remain.

ON DISINFECTANTS.

DR. A. J. BERNAYS, Lecturer on Chemistry at St. Thomas's Hospital, London, in a letter to the *Times*, writes as follows: —

In employing a disinfectant, it should be borne in mind that we sometimes have to deal with bodies in a state of decomposition, evolving gases more or less known to chemists; at other times with matters not so advanced, in a solid state, but not volatile.

The gases evolved from putrefying animal matter, and those of most injurious quality, are generally hydrogen compounds. Now these should be dealt with by volatile disinfectants; if possible, by gases. Now there is no gas to equal chlorine; there is none so cheap, so thoroughly effective in altering the character for good of noxious gases, and none so easy of application. As long as it is in excess, or, in other words, preponderates over the injurious hydrogen compounds, it can be recognized by its odor. There is only one serious objection to chlorine — its smell; but if it be properly used, and not wasted, this objection is reduced to a minimum. Except in the case of closets, where it is best to dust a small quantity in the pan above the reach of water, a solution of the chloride of lime, in the proportion of one pound to ten pounds of water, is most adapted for disinfecting air. A rag as large as an ordinary handkerchief, steeped in such a solution, wrung out, and suspended in small rooms, will sweeten the air for twenty-four hours. The chlorine, slowly evolved, acts partly in decomposing injurious hydrogen compounds, partly in evolving ozone; chlorine is therefore a grand oxidizing agent.

I will not occupy your space by mentioning other gases, such as sulphurous and nitrous acids, but would only venture to point out that chloralum cannot be substituted for chlorine; a fixed, non-volatile substance cannot take the place as a disinfectant of volatile substances. When we come to disinfect decomposable matter, when it is our task to prevent such matter from decomposing, then we have generally to do with solid bodies. Here is my difficulty. How can I in a few words give an intelligible description? The compounds so capable of mischief are those which contain nitrogen, sulphur, and phosphorus; the best type of them we have in albumen, such as constitutes in a pure state white of egg. These albumen-like compounds form doubtless the germs about which so much is written by medical men. If, then, germs partake of the character of albuminoid bodies, for such there can be no better disinfectant than carbolic acid. Anyhow, as these bodies give rise to the most fetid gases, as they are abundantly present in all decomposing animal matters, and as they are completely coagulated by carbolic acid, it is very difficult to understand why carbolic acid is to be substituted by disinfectants which have no such power. The evil of carbolic acid is not in its poisonous nature; many more have been killed by chloride of zinc, which is nearly equal to chloralum. No, rather is it to be sought in the deceptive character of common carbolic acid. The impurities give the disagreeable and often disgusting smell, and the odors attaching may give quite a false notion of security. Sprinkled against bricks in a sewer, out of reach of water, all the smell supposed to proceed from carbolic acid may continue to be evolved for months, whereas nothing in the way of disinfection is being accomplished. A purer article at a much higher price would be really cheaper, because effective.

In conclusion, carbolic acid is readily diffused through air; chloralum is not. Both are good in their place, but the latter can no more pretend to take the place of carbolic acid than carbolic acid that of chloralum. Carbolic acid may coagulate germs and render them harmless; chloralum could do nothing of the kind.

MEDICAL MEMORANDA.

ROYAL DEATHS FROM SMALL-POX. — By way of impressing the ravages of small-pox in the pre-Jennerian period on people's minds in a manner more picturesque than that of ordinary statistics, says the *British Medical Journal*, Dr. John Gairdner selects the history of a few royal houses. Thus, of the descendants of Charles I., of Great Britain, he finds that of his 42 lineal descendants up to the date of 1712, five were killed outright by small-pox, namely: his son Henry, Duke of Gloucester, and his daughter Mary, wife of the Prince of Orange and mother of William III., and three of the children of James II., namely: Charles, Duke of Cambridge, in 1677; Mary, Queen of England and wife of William III., in 1694; and the Princess Maria Louisa, in April, 1712. This does not include, of course, severe attacks not fatal, such as those from which both Queen Anne and William III. suffered. Of the immediate descendants of his contemporary, Louis XIV., of France (who himself survived a severe attack of small-pox), five also died of it in the interval between 1711 and 1774, namely: his son Louis, the Dauphin of France, in April, 1711; Louis, Duke of Burgundy, son of the preceding, and also Dauphin, and the Dauphiness, his wife, in 1712; their son, the Duc de Bretagne, and Louis XV., the great-grandson of Louis XIV. Among other royal deaths from small-pox in the same period, were those of Joseph I., Emperor of Germany, in 1711; Peter II., Emperor of Russia, in 1730; Henry, Prince of Prussia, 1767; Maximilian Joseph, Elector of Bavaria, Dec. 30, 1777.

AMATEUR PRESCRIPTIONS FOR THE SICK PRINCE. — During the illness of the Prince of Wales many people came from all parts of the country with medicinal remedies for his Royal Highness. The *Pall Mall Gazette* remarks that this is not without precedent. "When Henry, Prince of Wales, was dying in November, 1612, of a fever which commenced with a chill, the only medicine that nearly succeeded in producing perspiration was a 'quint-essence' sent by Sir Walter Raleigh from his prison in the Tower for the use of the Prince, and it even produced a more marked effect than the pigeons which were applied to the head, or the split cock applied to the feet of the royal sufferer. The extreme anxiety shown by strangers to render medical assistance to those who, occupying prominent public positions, are attacked by illness is very remarkable, and speaks well for the general good feel-

ing that prevails in the world in spite of all the harsh judgments that are sometimes passed upon it. It is a well-known fact that when the late Lord Derby had an attack of gout, prescriptions and pill-boxes poured in upon him from all quarters, and were duly acknowledged, to the complete satisfaction of the kindly hands by whom they were forwarded. When Mr. Pitt was at the point of death, a stranger, it is said, appeared at his house at Putney-hill and requested permission to administer a remedy he brought with him, and which he felt convinced would be effectual. The doctors having exhausted all their resources gave the required consent, and a small quantity of what appeared to be a kind of oil was poured down the throat of the dying statesman by the visitor, without producing any other result than increased difficulty of breathing and other symptoms of distress. The effect of the experiment was not, in fact, such as to create confidence in the nostrums of amateurs, who spare the small, but, bottle in hand, hover round the bedsides of the great; still they are often well-intentioned people, and the disappointment they feel at the rejection of their advice is quite sufficient punishment for their offence, if offence it be, without their being made the objects of ridicule."

Women as Nurses. — The London *Saturday Review*, in an article entitled "In Sickness," remarks as follows: "In sickness, too, who but women can nurse? Men make good nurses enough out in the bush, where nothing better can be had; and a Californian 'pardner' is tender enough in his uncouth way to his mate stricken down with fever in the shanty, when he comes in at meal times and administers quinine and brick tea with horny hands begrimed with mud. But this is not nursing in the woman's sense. To be sure the strength of men makes them often of value about an invalid. They can lift and carry as women cannot, and the want of a few nights' sleep does not make them hysterical. Still they are nowhere as nurses, compared with women; and the best of them are not up to the thoughtful cares and pleasant attentions which, as medical men know, are half the battle in recovery. And this is work which suits women. It appeals to their love of power and tenderness combined, and gratifies the maternal instinct of protection and self-sacrifice, while it pleasantly reverses the usual order of things, and gives Samson, blind and bound, into their hands."

Hypodermic Injection of Morphia. — In the London *Practitioner*, Dr. Sleightholme gives his experience in the hypodermic injection of morphia, while house physician to the Manchester Royal Infirmary. He says that he gave at least two thousand injections of morphia to patients suffering with various complaints. From these cases he never saw any immediate ill effect from the injection, and but one instance of ill result from prolonged use. In delirium tremens he found that usually the hypodermic injection of morphia increased the excitement. The delirium from injuries was increased by the same treatment. Neither was acute chorea benefited by injected morphia. In acute rheumatism, valvular disease of the heart, and aneurism, the injection had a most happy effect. In general, he says, when hypodermic injections of morphia are used to relieve pain they invariably succeed, no matter how severe the pain may be; that when sleep was prevented by severe pain, the pain was relieved and sleep followed.

POISONOUS "HAIR RESTORERS."

We have referred more than once to the mischief done by hair dyes, "restorers," etc., containing lead. A medical correspondent of the *Country Gentleman* states that he has under his care two ladies, one of whom "has been paralyzed on the right side for nearly three years, and has been utterly helpless most of that time. Her vision has been very imperfect; her knowledge of past events has utterly departed from her; recently she appears to be recovering her recollection, and can count with tolerable accuracy as high as twenty." He attributes her prostration entirely to the use of a popular hair restorer. "The other case is not so bad, but bad enough. For the past year her eyes have been an occasion of constant torture. The retina has become so sensitive to the light as to make a dark room indispensable. Wheels of burning flame revolve constantly before her eyes, attended by lightning-like flashes, which are terrible to bear. She is another victim to the poisonous lead contained in the same popular hair-restorer."

Since writing the above, we find another case of the kind reported in the *Boston Medical and Surgical Journal* by Dr. J. M. Crocker, of Provincetown, Mass. "R. W., aged 55, laborer, was attacked with what appeared to be muscular rheumatism, affecting mainly the deltoid and other muscles of shoulders, last February. When first visited, he was suffering from pains which he had felt more or less severely for a month or two. Both arms were in this manner crippled. Ordered cotton batting to affected parts, lemon-juice and opiates internally. Made quite a rapid recovery, but when seen in March following, he was suffering from an almost complete paralysis of extensor muscles of fingers and hands, with dropping of wrists. He could readily and forcibly grasp, but found difficulty in letting go. Subsequently, upon inquiry, I discovered that for fifteen years he had used a 'hair renewer,' made by himself of three teaspoonfuls lac sulphur and two teaspoonfuls sugar of lead to a pint of water. With this he had drenched his hair and scalp as often as once a week. Under use of iodide of potassium and galvanism, he has made a good recovery, the hair-dressing having of course been discontinued."

A SIMPLE REMEDY FOR DANDRUFF.

There are doubtless few persons, especially among gentlemen, who do not suffer from the inconvenience of dandruff. Physicians seem to consider it not of sufficient importance to engage their attention, and the poor victims are left either to practise their virtue of endurance, or for a cure, to try some of the many nostrums advertised in the public prints.

The intolerable itching which frequently accompanies the troublesome complaint is not the only unpleasant feature, as, to persons of any pretensions to neatness, the appearance of the white scales on the coat-collar and shoulders is very objectionable.

The writer, during a number of years, tried the different alcoholic solutions of castor-oil, and many other preparations, without permanent benefit, and, as a last resort, was led to adopt the plan of cleaning the scalp with borax and carb. potassa. This proved effectual, but after a persistent treatment of some months the hair became sensibly thinner, and perhaps would have soon disappeared altogether. The belief that dandruff arises from a disease of the skin, although physicians do not seem to agree on this point, and the knowledge that the use of sulphur is frequently attended with very happy results in such diseases, induced me to try it in my own case. A preparation of one ounce of flowers of sulphur and one quart of water was made. The clear liquid was poured off, after the mixture had been repeatedly agitated during intervals of a few hours, and the head was saturated with this every morning. In a few weeks every trace of dandruff had disappeared, the hair became soft and glossy, and now, after a discontinuance of the treatment for eighteen months, there is no indication of the return of the disease. I do not pretend to explain the *modus operandi* of the treatment, for it is well known that sublimed sulphur is almost or wholly insoluble, and the liquid used was destitute of *taste*, *color*, or *smell*. The effect speaks for itself. — *Journal of Pharmacy.*

SELECTED FORMULÆ.

Colors for Druggists' Show Bottles. — *Amber.* — Dragon's blood, in coarse powder, 1 part; oil of vitriol, 4 parts. When thoroughly dissolved dilute with cold distilled water till the required tint is obtained. *Lilac.* — Dissolve oxide of cobalt in hydrochloric acid, adding sesquicarbonate of ammonia in excess, and afterwards sufficient ammonio-sulphate of copper to bring the desired color. *Orange.* — Dissolve bichromate of potash in water and add a little sulphuric acid. *Violet.* — Mix together solutions of nitrate of cobalt and sesquicarbonate of ammonia, adding a sufficiency of ammonio-sulphate of copper to strike the required color. *Blue.* — Take of solution of perchloride of iron 10 drops, yellow prussiate of potash 10 grains, oxalic acid 2 drachms, water 1 gallon. *Red.* — Solution of perchloride of iron 10 drops, sulphocyanide of potassium 10 grains, water 1 gallon. *Crimson.* — Iodine and iodide of potash, of each 30 grains, hydrochloric acid 1 drachm, water 1 gallon. *Green.* — Sulphate of copper 1 drachm, bichromate of potash 30 grains, strong liquor of ammonia 2 ounces, water 1 gallon.

Balsamic Cigarettes for Asthma, etc. — The London *Chemists' and Druggists' Compendium* gives the following recipe: Soak strong unsized paper in a solution of saltpetre; this dry, and treat first with tincture of cascarilla, and afterwards, when nearly dry, with compound tincture of benzoin; cut into squares of a suitable size, and roll into the form of cigarettes.

Transparent Amandine. — The following is from the same authority: Take of fine white honey 4 ounces, fine white soap 2 ounces; mix these well in a mortar, adding one ounce liquor potassa, until the mixture becomes a perfect cream; rub in with caution and slowly 7 pounds of almond oil (sweet), and 1 oz. of essential oil of bitter almonds, adding to taste a sufficiency of oils of bergamot and cloves, and lastly, half a drachm of balsam of Peru.

Lavender Water. — The following is a superior preparation by Dr. Pereira: Oil of lavender (flowers) 3 drachms, oil of bergamot 3 drachms, oil of roses (otto) 6 drops, oil of cloves 6 drops, musk 2 grains, oil of rosemary (best) 1 drachm, honey 1 ounce, benzoic acid 40 grains, rectified spirit 20 ounces, water 3 ounces.

Aromatic Vinegar. — Take of camphor 1 ounce; oil of cloves, 1 drachm; oil of lavender, 40 drops; oil of rosemary, 40 drops; glacial acetic acid, 10 ounces.

Dispensary for Skin Diseases. — A most beneficent charitable institution has been opened in this city at 241 Harrison Avenue. It is a Dispensary for Skin Diseases, a free hospital in which all diseases of the skin are treated on Mondays, Wednesdays, and Saturdays of each week, at 11½ o'clock. Dr. Wigglesworth is the skilful surgeon in charge, and patients in his hands will receive all attention and medical and surgical treatment necessary.

Rush Medical College, Chicago. — We desire to call attention to this medical school, as during the great conflagration in Chicago the college building was utterly destroyed. The college has secured the lecture and clinic rooms of the Cook County Hospital, and the regular session will commence on Wednesday, March 6, and continue until June 26. The college has an able corps of instructors, and students will receive as thorough instruction here as at any institution in the country.

Familiar Science.

THE SOLAR ECLIPSE OF DECEMBER 12, 1871.

BY PROF. C. A. YOUNG.

The article upon this eclipse which appeared n the last number of the Journal, though ›urposely delayed as long as possible, was ıardly in type before fuller accounts of the ob- ervations began to be received in the form of etters published in the different popular and cientific periodicals: thus far communications ıave come to hand from Lockyer, Maclear, ?ringle, Respighi, Janssen, and Tennant.

And first, one or two errors in the previous ırticle must be corrected. It seems that Bekul, ›r Baikul, where Mr. Lockyer observed, is not n or near Ceylon, but on the western coast of ndia, about twenty-five miles south of Manga- ›re. Manantoddy, where Abbay was stationed, s also west of Dodabetta, about half-way be- ween it and Bekul. At this station alone the veather was bad and prevented observation. Poodoocottah, Respighi's station, is on the east- rn side of the peninsula, some twenty miles rom the sea; and the only stations in Ceylon vere at Jaffna and Trincomalee.

A more important correction relates to the emark as to the "Frenchiness" of Janssen's elegrams. I am happy to say it does him in- ustice, for in subsequent letters he removes the round of complaint. Taking the telegram by self, however, it naturally suggests the remark › any one who has had occasion to be familiar ith the cool manner in which, ever since the ays of Descartes, French *savants* have too often nored the previous work of other nationalities, ıd claimed foreign discoveries as their own.

I translate a portion of one of Janssen's tters: —

"In my telescope the spectrum of the corona ›pears not continuous but remarkably complex. found in it the bright lines of hydrogen, which rms the principal element of the protuberances and e chromosphere; the brilliant green line already ›served in the eclipses of 1869 and 1870, and some her fainter ones; and finally some of the *dark* ıes of the ordinary solar spectrum, notably D: ese lines are much more difficult to perceive.

"My observations prove that, independently of the ›smical materials which must exist in the neigh- rhood of the sun, there exists around this body an mosphere very extensive and excessively rare, ith hydrogen for its basis (à base d'hydrogène). his atmosphere, which undoubtedly forms the out- le gaseous envelope of the sun, is fed by the aterial of the protuberances projected with such olence from the bowels of the photosphere, but is stinguished from the chromosphere and the pro- berances by a density enormously less, a lower mperature, and perhaps by the presence of cer- in different gases.

"There is then reason to assign a distinctive me to this new solar atmosphere. I propose to call it the *coronal atmosphere*, a designation which indicates that it produces the principal portion of the luminous phenomena which thus far go by the name of the Solar Corona.

"In announcing this result I do not forget for my part, how much we owe to the labors which have prepared the way for it; notably those of the American astronomers in 1869 and 1870."

The only objection to be made to this is that he should speak of his own observations as proving instead of confirming a discovery made in 1869, and fully established in 1870. The name *leucosphere* was proposed for this "coronal atmosphere" by Lieutenant Brown, last year, but has not been generally adopted.

The observations of M. Janssen at Sholoor, however, agree with those at nearly all the other stations, in demonstrating the presence of hydrogen in this upper atmosphere — an exceedingly important addition to our knowledge. Some of the hydrogen lines were indeed seen in 1870 by nearly all the observers, but since they were also seen almost as well on the surface of the moon itself as anywhere else outside of the chromosphere, their presence was generally attributed to simple atmospheric glare — I certainly thought so, wrongly as it seems. What decides the matter, however, is not that the hydrogen lines were seen, but that the D^3 line, so called, which in the spectrum of the chromosphere is brighter than the F and G lines, was *not* seen: this fact, which cannot be accounted for on the supposition of a mere reflection, comes out very strikingly in the observations of Lockyer and Respighi. Janssen also deserves great credit for his success in bringing out for the first time the dark Fraunhofer lines in the corona spectrum. He owes this success to his magnificent instrument, a reflector of 14 inches aperture and only 56 inches focal length, giving an image from 12 to 15 times brighter than common, and fitted with a corresponding spectroscope.

The observation of the eclipsed sun through a train of prisms, by Mr. Lockyer, which was so confusedly described in the letter quoted last month, gave the following result: He saw four exquisitely colored rings, with projections in each directly above the prominences visible on the sun's limb. One of the rings was a brilliant scarlet, answering to the C line of hydrogen; the second was green (1474); the third blue (F); and the fourth violet (2796). Furthermore, the rings were all of about the same height, estimated at 2′, and the green zone was the faintest. What is singular about the result, and contrary to what might have been expected, is not, as Mr. Lockyer seems to think, the faintness of the 1474 ring, but the fact that it was no larger than the others, and only 2′ instead of 8′ or 10′ high.

Respighi's result, however, agrees better with my own expectations. Observing in a manner essentially similar, but with a telescope instead of the naked eye, he saw the same rings except the one in the violet, and describes them thus:

"The green zone surrounding the disc of the moon was the brightest, the most uniform, and the best defined. The red zone was also very distinct and well defined, while the blue zone was faint and indistinct. The green zone was well defined at the summit, though less bright than at the base: its form was sensibly circular, and its height 6′ or 7′. The red zone exhibited the same form and approximately the same height as the green, but its light was weaker and less uniform."

Both observers agree in this, — neither of them saw any yellow zone corresponding to the D^3 line, nor did they see anything of the coronal streamers through the prism. The significance of the first fact has been already indicated. The second goes to show (though considering their faintness it does not quite make it certain) that the streamers differ in their nature and material from the coronal atmosphere; it does not by any means, however, follow that they are not solar in their origin.

The reversal of the Fraunhofer lines seems to have been satisfactorily observed by Captain Maclear at Bekul, Colonel Tennant at Dodabetta, and Captain Fyers at Jaffna. It was partially seen by Pringle at Bekul, and Respighi at Poodoocottah, and probably by Pogson at Avenashi. How it was with Janssen I do not know. His instrument, however, on account of the small size of the sun's image, was not very well adapted for this observation.

Mosely, at Trincomalee, did not see it. Mr. Lockyer missed it by an accidental derangement of the telescope. He says further, "At the last contact Mr. Pringle watched for it and saw no lines." How the mistake occurred I do not understand, but Mr. Pringle's own words are, "At the end of totality a considerable number of lines flashed in; what proportion of the whole I cannot say, perhaps one third."

Captain Maclear writes, "As totality came on the light decreased, and the lines increased exceedingly rapidly in number and brightness, until it seemed as if every line in the solar spectrum was reversed: then they vanished, not instantly, but so rapidly that I could not make out the order of their going."

This description applies exactly to what I saw in 1870, except that the lines then made their appearance more suddenly — they flashed out like the stars from a rocket head; but the discrepancy is easily enough accounted for by supposing that the portion of the sun's limb last covered by the moon was then more quiet than at the time of Captain Maclear's observation.

As to the polariscopic results, Mr. Lockyer and his associate, Dr. Thompson, found strong vertical polarization over everything. At Jaffna Captain Tupman and Mr. Lewis found it as strongly radial: so also Oudemans at Batavia. Mr. Pogson's result is announced as "satisfactory," but whether that means vertical or radial

I am sure I do not know. The old puzzle evidently remains.

There is nothing further as to the comparison of photographs, 5 of which were obtained at Bekul, 6 at Dodabetta, 3 at Avenashi, and 6 at Jaffna, besides a few others by amateurs at different stations. Probably it will be necessary to wait until the parties have all returned to England before we hear the result, which can hardly fail to be interesting and instructive.

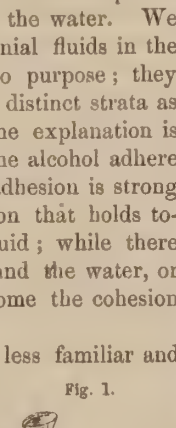
DARTMOUTH COLLEGE, *March* 1, 1872.

THE DIFFUSION OF LIQUIDS.

THE mixing of liquids is a very familiar process, and the fact that certain liquids will not mix is equally well known. If we pour alcohol into water, the two soon become uniformly mingled, but if we try the experiment with oil instead of alcohol, the oil rises to the top and remains entirely separate from the water. We may stir or agitate the uncongenial fluids in the hope of blending them, but to no purpose; they hasten to arrange themselves in distinct strata as soon as we let them alone. The explanation is a simple one: the particles of the alcohol adhere to those of the water, and this adhesion is strong enough to overcome the cohesion that holds together the particles of each liquid; while there is no adhesion between the oil and the water, or none that is sufficient to overcome the cohesion of the liquids.

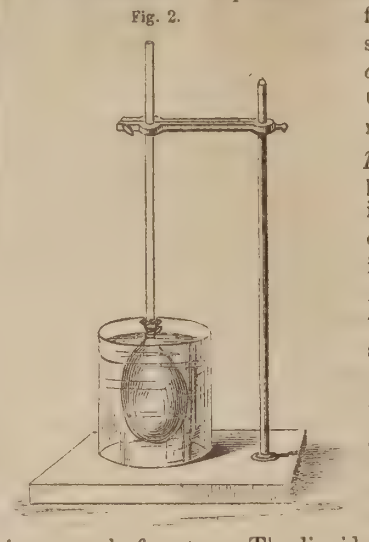
The *diffusion* of liquids is a less familiar and a less simple phenomenon. If we put some colored alcohol into a tall glass jar, and then by means of a long tube, as shown in Figure 1, pour in water very carefully, the latter will remain for some time at the bottom of the vessel, and the line of separation from the alcohol will be sharply defined; but if the liquids are left to themselves for a day or two, the color will show that they have become thoroughly mingled. If sulphuric acid is poured in this way into the bottom of a vessel containing water colored with litmus or red cabbage, the change in the color of the vegetable dye enables us to trace the gradual intermingling of the acid with the water. This mixing of liquids that are merely brought in contact is what is meant by their *diffusion*. The laws of this diffusion have been carefully investigated by Graham and others, but it would take too much space to state them in full. Suffice it here to say that the rapidity of the diffusion varies remarkably with the nature of the liquids, or (in the case of solutions of the same substance) with the strength of the solution, with the temperature, and with certain minor conditions. To illustrate the variation in the rate of diffusion, we may mention that hydrochloric (or muriatic) acid diffuses into pure water seven times as fast as syrup of sugar, and the latter seven times as fast as albumen, or the white of an egg. In some cases, chemical decomposition may be effected by diffusion: thus potassic bisulphate is separated into free sulphuric acid and potassic sulphate.

Fig. 1.



Liquids will mingle even when separated by a thin membrane or porous substance, and this form of diffusion is called *osmose*, from a Greek word meaning *impulse*. A simple experiment in the osmose of liquids is illustrated in Figure 2. Tie the neck of a bladder air-tight about the end of a long glass tube, fill the bladder with alcohol, and immerse it in a vessel of water. The liquid will gradually rise in the tube, showing that water has passed into the bladder. The water in the vessel will also be found to contain alcohol, which has been passing out, but with a slower current, while the water has been passing in. The inward current is sometimes called *endosmose*, and the outward one *exosmose*. The rate of diffusion varies with the liquids used, and with the substance employed to separate them. If we use a small collodion balloon instead of the bladder, the fall of the liquid in the tube shows that the alcohol passes out faster than the water comes in. If the bladder is filled with sugar syrup instead of alcohol, the inward flow of the water is far more rapid than the outward flow of the syrup, as is proved by the rise of liquid in the tube.

Fig. 2.



In cases like this, the phenomena are apparently due to the combined effect of capillary attraction and diffusion. The water is absorbed by the bladder (that is, drawn into its pores by capillary force) more rapidly than the alcohol or syrup. The first effect, then, is to saturate the bladder with water containing a slight admixture of syrup — to confine our attention to that experiment. On the outside of the bladder, this water slightly mixed with syrup is diffusing into pure or nearly pure water, which will necessarily be a slow process; on the inside, water nearly pure is diffusing into strong syrup, and as this will be a quicker process the quantity of water entering will be greater than that of syrup escaping.

But there are other cases of osmose that are by no means so easily explained, and the laws that govern the process are as yet but imperfectly understood. The subject is an interesting and important one, since it embraces such phenomena as the motion of the sap, and of other fluids in plants and animals, with the dependent processes of absorption, secretion, and in short, almost everything that is most intimately connected with organic *growth*.

MAPLE SUGAR.

THE formation of the sugar in the sap of the maple, like many other organic processes, is not perfectly understood by chemists, but the following facts are well ascertained, and afford a partial explanation of the mystery. In the latter part of the summer considerable starch and similar substances are deposited in the cells of the sap wood of trees. These are the stores laid up for the manufacture of the foliage for the next summer. When spring comes the roots of the trees wake up from their winter sleep and imbibe large quantities of water from the soil, long before the buds begin to swell. This water is of course charged with various salts, some of which, like carbonate of lime, are held in solution by the carbonic acid contained in the water, while others are soluble in pure water. This water is gradually carried up the stem of the tree by capillary attraction and by osmose; but as it ascends through the cells it converts some of their contents into sugar, becoming denser and more saccharine as it rises, until finally it reaches the buds. If now the weather is warm enough, the buds expand and soon burst into leaves and flowers. The first energies of the tree are devoted to perfecting these important parts; and when this is accomplished the leaves commence to prepare the material for the growth of another year. This is deposited in the new layer of wood which is formed directly under the bark, ready to be taken up again the next spring for the formation of new twigs and leaves and thus the circulation goes on from year to year. The only part of the trunk that takes any active part in the circulation is the sap or light colored wood. The old dark portion of the wood in the interior has become clogged up with insoluble matter, and is no longer capable either of conducting sap or of performing any other function in the economy of the tree.

If we wish to make sugar from the sap of any tree, it must be tapped at the time of year when it is most abundantly charged with that liquid, and this is usually a month or two before the leaves begin to expand. Nearly all our hardwood trees will yield more or less sugar, but only a very few of them furnish it in large quantities or pure enough for domestic use. The *Acer* or Maple family stands at the head of the list in this respect, and chief among these is the *Acer saccharinum* or sugar maple, the juice of which contains from three to six per cent. of cane sugar. That which comes from the tree when it is first tapped is much richer than that which flows later in the season. The first sap ascending the stem naturally dissolves out the largest proportion of the starch and gum.

After the sap is drawn it is concentrated by boiling until it commences to crystallize, when it is allowed to cool and deposit the sugar. During this concentration of the sap the lime salts which have been held in solution are gradually precipitated as the syrup becomes more dense. This deposit or "nitre," as it is called, consists according to some authorities, of carbonate of lime; others consider it to be malate of lime or saccharate of lime.

The flow of sap varies much with the state of the weather, being most abundant when the nights are cool and the days warm. This has been explained on the supposition that on warm days the air contained in the trunk of the tree expands, thus forcing the sap out; while as the tree cools off at night the air contracts, and the sap rises from the roots to supply the vacuum, to be again forced out the next day. As soon as the leaves commence to expand the flow ceases, because then the leaves are able to evaporate all the water that the roots can supply. But

he continual tapping of the tree and the withrawal of its stores of nourishment soon causes t to languish, and it cannot survive such treatment many years any more than a man could survive the loss of a considerable portion of blood each day.

THINGS WORTH NOTING.

"THERE IS NOTHING NEW UNDER THE SUN." — n "Arthur Young's Travels," published in 1793, here may be found the following suggestion of an lectric telegraph: "In the evening to Mons. Loand's, a very ingenious and inventive mechanic. n electricity he has made a remarkable discovery. You write two or three words on a paper; he takes with him into a room, and turns a machine enlosed in a cylindrical case, on the top of which is n electrometer, a small fine pith ball. A wire onnects with a similar cylinder and electrometer in distant apartment, and his wife, by remarking the orresponding motions of the ball, writes down the ords they indicate, from which it appears he has ormed an alphabet of motions. As the length of he wire makes no difference in the effect, a correpondence might be carried on at any distance; within and without a besieged town, for instance, or or a purpose more worthy and a thousand times nore harmless, between two lovers prevented from ny better connection. Whatever the use may be, he invention is beautiful."

Photography was suggested even earlier. In Dr. Hooper's "Rational Recreation," 1774, is the following method of writing on glass by the rays of the un: "Dissolve chalk in aquafortis to the consistence of milk, and add to that a strong dissolution f silver. Keep this liquor in a glass decanter, well toppered. Then cut from a paper the letters you vould have appear, and paste the paper on the decanter, which you are to place in the sun in such a manner that its rays may pass through the spaces ut out of the paper, and fall on the surface of the iquor. The part of the glass through which the ays pass will turn black, and that under the paper ill remain white."

HOW TO USE THE THERMOMETER. — Signal fficer Singleton, of St. Louis, alluding to some tatements respecting discrepancies between governent reports of the weather, the state of the therometer, etc., and those made by private individuals, ays: "A thermometer should be placed in an open pace, out of the vicinity of high buildings, or any bject that impedes the free circulation of air. It hould face the north, to be always in the shade, hould be twelve inches from every neighboring bject, should be about fifteen inches from the ground, nd should be protected against its own radiation to he sky, and against the light reflected from neighboring objects, or the ground itself. The thermometer should be read as rapidly as possible, as the eat from the body or the breath influences the instruent. I have taken a thermometer belonging to gentleman in this city, that read seven degrees bove the standard instrument in this office, and fter removing the back, which was of metal, painted lack and varnished (with a radiating power of wenty-seven degrees at night), placed it in my nstrument shelter, after ascertaining the error, by y standard (which was three tenths of a degree, he instrument being an imported article and very ne), and I found it to read exactly with the standrd. Out of 470 observations at all hours of the ay and night it varied but once, and then only wo tenths of a degree."

LOW BAROMETER IN POLAR REGIONS AND IN CYCLONES. — Observations show that there is a marked depression of the barometer in the polar egions and in the central part of cyclones; but no ery satisfactory explanation has as yet been given of the cause of this phenomenon. Reliable observations show that there is a depression of *more than one inch* below the average at the equator, in that portion of the Antarctic region which has been visited by observers, and about half as much in the Arctic region. It is also known that during the continuance of a cyclone the barometer stands from *one to two inches lower* in the central portion of the same, than when exposed in the exterior part.

ACCURACY OF TELEGRAPHIC DETERMINATION OF LONGITUDE. — In some work of this kind done for the United States Coast Survey, where the longitudes were estimated by four different circuits, the greatest difference between any two determinations was twenty-eight thousandths of a second, equivalent to about *thirty feet*, the mean error being less than one millionth of the distance between the two objective points, which, in some cases, as in that between Cambridge and San Francisco, was 3,580 miles.

HYGIENIC HINTS.

HARD AND SOFT BOILED EGGS. — It is well known that a soft boiled egg is more easily digested than a hard boiled one; but the difficulty is in the white, not in the yolk. Experiments have shown that the gastric juice will not act readily on the tough tenacious structure of firmly coagulated white of egg, even when cut in pieces as small as peas — or as fine as people usually chew their food — while it acts with facility on the more brittle yolk. To cook eggs so that they will be easily digested, put them into boiling water sufficient to cover them, and let them remain ten or fifteen minutes; keep the water nearly up to the boiling point, but do not let it reach that point. Fresh eggs will cook sooner than old ones, and small ones than large ones. By this process the yolks will be well cooked, while the white does not become tough and hard to digest.

THROAT AND LUNG DISEASES. — Most of the throat and lung diseases, which indirectly lead to consumption, are occasioned by sheer carelessness. A delicate woman often sits for two or three hours in a crowded theatre or church, breathing an atmosphere tainted by the exhalations from the lungs of hundreds of other people, her system is exhausted, her skin is excited by unwonted action, and when she leaves the building and goes out into the cold air her blood is suddenly driven to the interior of the body, and then ensues a more or less permanent congestion or inflammation of some of the internal organs — usually the air tubes in or leading to the lungs. This process being repeated many times, a chronic bronchitis is finally established in persons otherwise healthy, and life is ever after rendered miserable by this periodical overheating and sudden chilling of the body, even if the more dangerous malady, consumption, does not interfere, and put the abused body into the grave.

READING IN RAILWAY CARS. — The *Philadelphia Medical and Surgical Reporter* has the following sensible remarks on this subject, and we commend them to the attention of all who ride much by rail: —

Most, if not all who read on railroads, are sensible of weight and weariness about the eyes. This sensation is accounted for on high medical authority by the fact that the exact distance between the eyes and the paper cannot be maintained. The concussions and oscillations of the train disturb the powers of vision, and any variation, however slight, is met by an effort at accommodation on the part of the eyes. The constant exercise of so delicate an organ of course produces fatigue, and if the practice of railroad reading is persisted in must result in permanent injury. Added to this difficulty is bad or shifting light. The safe and prudent mode is to read little if any. The deliberate finishing of volumes in railway cars is highly detrimental.

IN-DOOR LIFE.

ONE chief respect in which our severe climate and our over-stimulating social condition harass us, is the excessive preponderance of in-door activity which they involve. Now man is not yet an in-door animal, though he seems to be in a fair way to become one ultimately. The intense pleasure and the renewed vigor which we feel in summer picnickings may serve to indicate the extent to which our old barbaric needs still assert themselves in our mental and physical constitution. We cannot, however, again become out-door barbarians; nor is it urged that barbaric life is more conducive to health than civilized life. We may nevertheless learn from the savage one all-important hygienic lesson. In innumerable ways the savage violates the laws of health; but he at least breathes pure air, and his blood is rapidly oxygenated. Now one of the worst features, perhaps the very worst, of our in-door activity is the way in which it interferes with the due aeration of our blood. And this is a feature of in-door life which we can and must obviate. Partly due to imperfect science, but still more to unpardonable carelessness of the plainest rules of hygiene, is the unquestioned fact that our houses, our schoolrooms, our theatres, and our public conveyances are, as far as the atmosphere is concerned, foul dens of corruption. He who will read, for example, the two interesting papers on "Rebreathed Air," and on "Experiments with Air-Furnaces," in Dr. Nichols's just-published "Fireside Science," will not fail to appreciate the justice of our emphatic epithet. In these days of prohibitory liquor laws and anti-tobacco agitation, we may profitably bear in mind that the Indian weed (if practically a poison at all, which may be doubted) is far less poisonous than the carbonic oxide which burning anthracite invariably generates; and that where whiskey has slain its thousands, rebreathed air has slain its tens of thousands. Indeed, it may be seriously questioned whether the latter demon is not a secret but powerful ally of the former, producing as it does that anæmia, or deficiency of red blood disks, which may well be supposed capable of urging the jaded system to solace itself by alcoholic stimulation. From the moral point of view our more just and enlightened posterity will probably regard the Pennsylvania coal monopolists of our time very much as we regard the Rhenish barons of the twelfth century, who used to levy black-mail on every innocent traveller; and from the scientific point of view they will probably look back upon us in our over-heated and foul-aired houses with the same sort of pity with which we look back upon our ancestors in their un-chimneyed, undrained, and plague-producing hovels. However this may be, it is incumbent on us, as our chief hygienic duty, on the one hand, to devise some efficient method of carrying rebreathed air out of our houses, and, on the other hand, either to cease using anthracite for domestic purposes, or to invent (if it be possible) some kind of stove or furnace which will not cause our faces to flush and our temples to throb under the influence of Stygian blasts of carbonic oxide.

In passing, we may observe that Dr. Nichols's little book above mentioned, under the title of "Fireside Science," contains a number of short essays, all of which are well worth reading, and many of which are of considerable practical value. — *Atlantic Monthly.*

THE UNWEARIED ACTION OF THE HEART.

THE effect of everything that touches the heart is multiplied by the intensity of the heart's own changes. Hence it is that it is so sensitive, so true and quick an index of the body's state. Hence, also, it is that it never wearies. Let me remind you of the work done by our hearts in a day. A man's total outward work, his whole effect upon the

world in twenty-four hours, has been reckoned about 350 foot-tons. That may be taken as a good "hard day's work." During the same time the heart has been working at the rate of 120 foot-tons. That is to say, if all the pulses of a day and night could be concentrated and welded into one great throb, that throb would be enough to throw a ton of iron 120 feet into the air. And yet the heart is never weary. Many of us are tired after but feeble labors; few of us can hold a poker out at arm's length without, after a few minutes, dropping it. But a healthy heart, and many an unsound heart, too — though sometimes you can tell in the evening, by its stroke, that it has been thrown off its balance by the turmoils and worries of life — goes on beating through the night when we are asleep, and when we wake in the morning we find it at work, fresh as if it had only just begun to beat. It does this because upon each stroke of work there follows a period, a brief but a real period of rest; because the next stroke which comes is but the natural sequence of that rest, and made to match it; because, in fact, each beat is, in force, in scope, in character, in everything, the simple expression of the heart's own energy and state. — *Appletons' Journal.*

CULINARY RECIPES.

Boiling Potatoes. — To boil a potato well requires more attention than is usually given. They should be well washed and left standing in cold water an hour or two, to remove the black liquor with which they are impregnated, and a brackish taste they would otherwise have. They should not be pared before boiling; they lose much of the starch by so doing and are made insipid. Put them into a kettle of clear cold water, with a little salt, cover closely and boil rapidly, using no more water than will just cover them, as they produce a considerable quantity of fluid themselves while boiling, and too much water will make them heavy. As soon as *just* done, pour off the water instantly, set them back of the range, and leave the cover off the saucepan till the steam has evaporated. They will then, if a good kind, be dry and mealy. This is an Irish recipe, and a good one.

Potato Salad. — Any one who has eaten potato salad at a Parisian hotel will be glad to try it after he gets home. The following is a good formula for the simple but delicious preparation. Cut ten or twelve cold boiled potatoes into slices from a quarter to half an inch thick; put into a salad bowl with four tablespoonfuls of tarragon or plain vinegar, six tablespoonfuls of best salad oil, one teaspoonful of minced parsley, and pepper and salt to taste; stir well, that all be thoroughly mixed. It should be made two or three hours before needed on the table. Anchovies, olives, or any pickles may be added to this salad, as also bits of cold beef, chicken, or turkey if desired; but it is excellent without these.

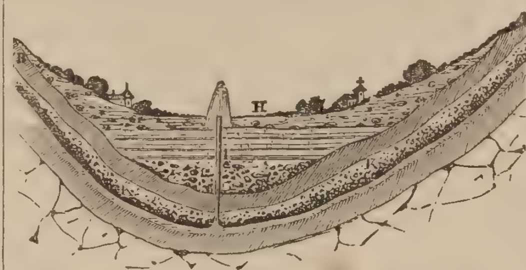
Sweet Potato Balls. — First boil the potatoes, then carefully mash the farinaceous part. Boil in the mean time a pint of milk, put in some lemon peel, a couple of small lumps of sugar, and a little salt. When the milk boils, take it off the fire and add the potatoes, so as to form a paste, or rather a tolerably thick mush. When cool, make it into balls; cover these with crumbs of bread and yolk of egg. Fry to a nice brown color, and serve up with sugar strewed over them.

A Relish for Breakfast or Lunch. — Take a quarter of a pound of good, fresh cheese; cut it up in thin slices and put in a spider, turning over it a large cupful of sweet milk; add a quarter of a teaspoonful of dry mustard, a dash of pepper, a little salt, and a piece of butter as large as a butternut; stir the mixture all the time. Have at hand three Boston crackers finely powdered or rolled, and sprinkle them in gradually; as soon as they are stirred in, turn the contents into a warm dish and serve.

The Arts.

ARTESIAN WELLS.

A correspondent wishes us to explain why the water in artesian wells often rises to the top of the well or even higher, like a fountain supplied by a reservoir situated above the outlet. It is simply because the well *is* virtually such a fountain. The water rises in the effort to regain its level, as the accompanying figure may serve to show. Suppose B and D to be two strata of clay, or some formation impermeable to water, and K to be a stratum of sand or gravel between them. The rain that falls on the hills at



either side will filter down through this sand or gravel, and collect in the hollow between the clay strata where it cannot escape. If now we bore down to K, the water thus confined will rise to the surface at H, or considerably above it. The height will depend upon the pressure of water which has accumulated in the sloping space between the impervious beds.

It will be readily understood that it is only where the nature and arrangement of the geological strata are such as we have described, that artesian wells can be expected to furnish water without the necessity of pumping. The province of Artois in France, from which these wells take their name, is a locality of this character; and the great cities of Paris and London are both favorably situated in this respect. The well at Grenelle in Paris is 1,798 feet deep, and the water rises at the rate of 516 gallons a minute, and with force enough to throw it 32 feet above the surface. In the London basin, as it is called, the porous cretaceous (or chalk) beds rest on the impervious "gault," and are covered with the equally impervious London clay; while on the higher grounds about the city the edges of the chalk bed are exposed and receive the rain-fall. Many wells have been sunk in this basin; among them those which supply the ornamental fountains in Trafalgar Square, and which penetrate to the depth of 393 feet.

Many of the waste places of the earth may yet be made fertile and habitable by means of artesian wells. Borings in the Great Sahara have been successful, and that immense desert may eventually be converted into fruitful fields. Extensive arid districts beyond the Mississippi are likely to be reclaimed in a similar way when the more favored portions of that region have been filled up.

MEMORANDA IN THE ARTS.

Railways in War. — A military committee has just been sitting at Berlin to inquire into the results of the employment of railways during the late war in the conveyance of troops, ammunition, provisions, etc. It is found that when the distance is short, and a considerable force has to be conveyed, it will proceed more rapidly on foot than by railway. An army corps of 36,000 men will go a distance of eighteen German miles in less time than if it were conveyed by a double line of railway, and a distance of twenty-seven miles in less time than if it were conveyed by a single line. A saving of time is only to be obtained in forwarding large bodies of troops by railway when the proportion of troops to German miles is as 2,000 to 1 on a double line, and as 1,333 to 1 on a single line. The French frequently suffered great losses from not observing this rule, while, on the other hand, they surpassed the Germans in employing railways for the conveyance of provisions. For this purpose so-called "magasins mobiles" were formed, each of which contained ten days' provision for an army corps, and was always kept ready on the line to be despatched wherever it might be wanted.

New Instrument for Measuring Speed at Sea. — The difficulties hitherto experienced in measuring the speed of ships, by any of the devices thus far produced, are said to be overcome by an ingenious instrument called the *rhysimeter*, lately invented in England. The indicator, which resembles a barometer in size and appearance, is located in the captain's cabin, a column of mercury showing constantly by its variations the speed which the vessel is making. Its accuracy is said to be perfect, there being no appreciable interference by friction or otherwise; and as the machine is self-registering, it may be made to keep a complete record of the speed of the ship throughout the voyage. The log and all substitutes for it heretofore employed have been found unreliable, especially in changeable weather, or under a heavy sea in either direction.

The rhysimeter is also designed for indicating the velocity of flowing liquids, which is in fact one of its most valuable uses, as it will greatly assist in the solution of many problems in practical hydraulics.

To Deodorize Kerosene Oil. — The odor of a substance is in most cases adherent, like color or any other physical property, and not accidental or extraneous. Where, as in the case of kerosene oil or the lighter petroleum naphthas, the substance is a mixture of many constituents, it is difficult to decide which of them is the objectionable one, and so long as this has not been determined, we can devise no rules for getting rid of it, or for destroying it in any other way. Practically, therefore, we are unable to deodorize the products, and especially the lighter ones, of the distillation of petroleum; but we may conceal them in the same way as formerly the disagreeable odors incidental to sick rooms and even to ordinary apartments were hidden by the liberal use of strong smelling liquids or the fumes of incense. The *Druggists' Circular* suggests that the best fluid for this purpose is the artificial oil of bitter almonds, or mirbane oil; a little of it will go a great way in disguising the odor of petroleum effectually, and as it has a very high boiling point, it will accomplish its purpose most durably.

Sodium for Blasting. — The application of sodium for the purpose of blasting is made as follows: Two glass bulbs 50 cubic centimeters capacity are blown with a neck of glass between them; one bulb is filled with sodium and the other with water, and between the two is fused a soluble salt. The length of time required to dissolve the salt can be ascertained by experiment, and the connecting tube be made so as not to have the charge fired prematurely. The bulbs, with the sodium below, are let down into the drill hole, the water gradually dissolves the salt, and thus comes into contact with the metal, and the explosion follows.

A New Thing for Photographers. — The *Scientific Press*, of San Francisco, describes a little contrivance invented by a photographer of that city, which will, we think, be found especially useful in

taking the pictures of children, as it dispenses with the great black cloth with which the tube of the camera is covered, and the removal and replacement of which, while the picture is being taken, tend to impair the result, by distracting the attention of the sitter. Instead of the cloth or brass cap which covers the tube of the camera, there is a disk of brass or other metal, consisting of two semi-lunar portions, which open and close like the blades of a pair of scissors. They are worked noiselessly and instantaneously by the slight pressure of a little knob on the top of the instrument, and the plate is exposed and closed again without any manipulations that can be seen by the sitter. The operator waits until the child assumes a favorable expression, when he presses the spring, exposes the plate, and takes the picture without making any motion that attracts the attention or causes a motion of his sitter. Like all useful inventions, this is exceedingly simple, and may be attached to any photographic camera.

PRACTICAL RECIPES.

Fine Green Bronze. — First boil the work in a strong solution of potash to get off all the old lacquer and grease; next wash in clear water; after that let the work stand a day or two in a weak solution of nitric acid, then take out, wash, and dry; then coat the article with some good black lead. Polish until you have a good black, glossy surface; then put on yellow lacquer, which, upon a black surface, gives a green bronze.

Useful Cement. — The following cement is found to be excellent for use in cases where it is desirable to join or close vessels for containing the vapor of acids, or highly corrosive substances. Beat and sift finely dry pipe clay; add painters' drying oil, and mix, in a mortar, to a moulding consistency. Use this lute in cylinders, flattened, and applied to the joinings. The points to which it is applied must be perfectly clean and dry.

Joining Rubber. — Rubber is easily joined and made as strong as an original fabric, by softening before a fire and laying the edges carefully together, without dust, dirt, or moisture between. The edges so joined must be freshly cut in the beginning. Tubing can be united by joining the edges around a glass cylinder, which has previously been rolled with paper. After the glass is withdrawn the paper is easily removed. Sift flour or ashes through the tube to prevent the sides from adhering from accidental contact.

Liquid Black-Lead Polish. — A recent English invention consists of black lead, such as is used for polishing stoves and for other uses, combined with turpentine, water, and sugar or saccharine matter, and the proportions which have been found to answer well are, to each pound by weight of black lead, one gill of turpentine, one gill of water, and one ounce of sugar; but these proportions may be varied, and in some cases all the ingredients are not necessary.

Elastic Varnish for Leather. — Take two parts by weight of resin, and one of india rubber, and heat them in an earthenware vessel till they are fused together; after which they should be stirred till they are quite cold; a little boiled linseed oil may be added while the materials are hot.

To Improve Gilding. — Mix a gill of water with two ounces of purified nitre, one ounce of alum, one ounce of common salt; lay this over gilt articles with a brush, and the color will be much improved.

A perfume for note paper, said to be that used by the Queen of England, is made of powdered starch, one half ounce; ottar of roses, ten drops. Put this in bags and keep in the desk with paper.

Agriculture.

FARM PENCILLINGS AT LAKESIDE.

MUCK.

The term *muck*, as used by farmers and agricultural writers, has a somewhat ambiguous meaning. It is often applied to cow-dung and stable manure, but usually the term is employed to designate the black, unctuous deposits found in meadows and low basins, and upon the margins of ponds. As these deposits differ most essentially in composition, the significancy of the word is not well defined. To obviate the confusion or perplexity which exists, we think there should be a distinction made between *peat* and other low land deposits, and they should have different names. Peat is the proper term to apply to the vegetable matter found in meadows in different stages of decay, and which is unlike the heavy, dark deposits, consisting of sand, clay, and vegetable *débris*, found in slough holes, ponds, etc. The difference between peat and this wash is very great, and the advantage in maintaining a distinction is obvious, as farmers will be better able to understand what deposits have some value and what have none. Peat, or pure vegetable deposits, may under some circumstances be worthy of attention, but wash or *mud* seldom is.

During the present winter we have observed, in our rides and walks in the country, farmers busily engaged in removing the heavy deposits from ponds left dry from the absence of rains. This labor, from the worthless character of the substance sought, was wholly unremunerative. An examination of one of these deposits in process of removal showed that sand and clay formed nearly fifty per cent. of the bulk of the material, water and a small amount of partially decomposed leaves and rushes made up the remainder. The black fragments of vegetable material gave to the mass a *dark* appearance, and hence it was supposed to have manurial value. Most fields would be positively injured by applying to them this heavy silt or mud, and the loss of time and labor to the farmer in removing it was a serious one. Before carting away such deposits, he should have taken a handful of the mixture and thoroughly diffused it in a quart of clear water. The sand and clay fall to the bottom of the vessel, and the lighter particles of vegetable material settle above, and by decanting or turning off the water after standing a few hours, a clear idea of the nature of the muck could have been obtained.

We are certain that the value of peat or muck, as a source of plant food, has been greatly exaggerated, and we hesitate not to say, that one of the most absurd books ever written is a "Muck Manual," compiled and published a dozen or more years ago; it has led farmers into quagmires and shaky bogs after materials which they were induced to suppose possessed a fertilizing value closely approximating that of animal excrement. This is a delusion which still exists to a very considerable extent, and occasions considerable disappointment and loss. What is the actual manurial worth of peat or the decomposed vegetable matter found in our meadows? Let us look into its nature carefully; let us dry it, weigh it, analyze it, and thus learn something positive concerning it. From a considerable number of analyses of peat, taken from different localities in New England, we will select two made the present winter as fairly representing both extremes, one a very good, the other a very poor article. The first and best was sent to us by J. S. Potter, Esq., of Newton, Mass., and it gave of —

Water	84.95
Ash	4.83
Organic matter	10.22
	100.00

The second came from Swampscott, Mass., and gave of —

Water	63.73
Ash	28.56
Organic matter	7.71
	100.00

A ton of the first specimen held *seventeen hundred pounds* of water, the second, *twelve hundred pounds*. The best contained about two hundred pounds of vegetable matter, the worst one hundred and sixty. What fertilizing value the specimens possessed is to be found in the ash and organic matter. The ash of the first was composed of sand, sulphate and carbonate of lime, oxide of iron, with traces of magnesia and soda; the second was largely made up of clay and sand with small quantities of lime. These mineral constituents are insignificant in value, although in one of the specimens large in amount. It may be said that the ash constituents of the last specimen are, practically, of little account, and the first holds but traces of the costly materials of plant food.

As regards the organic portion of peat it may possibly furnish food for plants both directly and indirectly, but our experiments with it in the field — and these experiments extend over a period of nearly ten years — have not afforded encouraging results. It is asserted by some writers that it furnishes carbon to plants, but this is doubtful. The leaves of plants elaborate carbon from the carbonic acid of the atmosphere; if the roots absorb it at all, it is in very limited quantities. There is no doubt whatever that peat, in its decay in the soil, furnishes carbonic acid in large quantities, but whether this is of any advantage to plants is not a settled point. Peats do contain nitrogen, but the amount is small; those found in the bogs of Massachusetts seldom rising above *one per cent.* of the dry mass. Assuming that dry peats of good quality supply on an average one per cent. of nitrogen, and the whole amount is utilized by plants, then one ton of raw peat yields three pounds, which at thirty cents gives the nitrogen value of the ton ninety cents. This nitrogen does not exist in the form of ammonia, as we have invariably failed to find ready formed ammonia in peats, and they do not contain nitric acid; therefore the nitrogen must occur in some inert or insoluble form, not perhaps largely available as plant food. It is impossible to state what the actual value of the nitrogen of peats may be, but we have good reason to believe that under the influence of moisture and air in soils, a portion of the gas at least is converted into ammonia or nitric acid, and therefore becomes available as a fertilizing agent. So far then as nitrogen goes, we have reason to believe that peat furnishes *some* valuable plant nourishment. If peat has the power of absorbing free nitrogen from the air, and if it is oxidized to nitric acid in the soil, then its *indirect* value should be regarded. We have a most ex-

cellent deposit of peat upon our farm, and have applied it to various kinds of soils, and, as before intimated, have studied its effects. Several of the years, or seasons, have been unfavorable for trial, from the extreme droughts; much of the dry, light vegetable matter lying upon the surface of our fields has been taken up by the winds and carried away. When perfectly dry it is as light as chaff, and is therefore easily moved by winds. Thus far, when treated with and without lime, we have failed to observe the least beneficial influence upon our crops. As an absorbent in cattle pens and barn cellars, it serves a good purpose, and if farmers can afford to draw and handle it, it should be collected. It also supplies a good adjunct to the compost heap, and seems to absorb ammoniacal and other gases; and its presence promotes changes in animal matter and in other fertilizing substances. We have not space fully to discuss this important subject in this number of the JOURNAL, and therefore it will be taken up again at a future time.

LOBSTER-SHELL MANURE.

Upon the coast of New England in the summer months, immense quantities of lobsters are taken, and after cooking are placed in hermetically sealed cans, and sold as food in all parts of the country. Some canning establishments in Maine consume in this industry thousands of tons each season; and consequently little mountains of shells accumulate, which are a source of annoyance to the owners of the factories. To utilize this product, the shells have been ground up and sold to farmers as manure. In order to ascertain the value of this substance, we have been employed to make analysis of it as sold in the market. It was found to contain of —

Water	15.90
Organic substances	42.13
Inorganic "	41.97
	100.00

In 100 parts it contains of —

Ammonia, actual and potential	3.50
Insoluble phosphoric acid	4.00

The insoluble phosphoric acid corresponds to 8.73 per cent. of bone phosphate, and the remainder of the inorganic portion consisted of carbonate and sulphate of lime. We learn from this determination that the lobster-shell manure has not a high value, — is not worth as much as a good quality of fish pomace. We presume the article as prepared at different factories would vary considerably in value, but the analysis will afford a very fair idea of its actual worth.

BONE CHARCOAL.

One of the important uses to which bones are applied is the production of a charcoal, which is largely used in decolorizing syrups in sugar refineries. If bones are burned in the open air, the animal portion is destroyed, and they crumble to a white powder; if they are placed in iron retorts and subjected to the influence of heat, a portion of the animal constituent is carbonized, and bone charcoal results. By either process, the earthy phosphates are not in the least disturbed, and the very best superphosphate of lime can be made from the substances by treating them with acids. We are this year using bone charcoal for making superphosphates for farm use, and we find no difficulty in producing an article which yields, upon analysis, *fifteen per cent. of soluble phosphoric acid.* This article we predict will "make the corn jump," as the phrase is, when the growing season fairly comes round. We have great confidence in well prepared phosphates, and fully believe that if we supply phosphoric acid in assimilable condition to soils, great benefits will result to our crops. The phosphates we *must* supply to exhausted lands, as not a plant can grow without them, and from no incidental sources can they proceed. Nitrogen, which has so great value in our manurial substances, may be furnished in abundance from the atmosphere or from rain water. It is certain that organic matter in soils has the power, to a greater or less extent, of changing atmospheric nitrogen into the two compounds from which alone it is made available as plant food. We are led from year to year to adopt more confidently Liebig's views upon this important point, inasmuch as we have observed that the nitrogenous element, when not directly supplied, was not wanting in any variety of plants if the phosphates were furnished generously.

HOME-MADE FERTILIZERS.

In preparing superphosphates upon the farm it is perhaps better to employ bones that have been calcined or charred, as a dry powder results from a proper admixture of acid with such materials, and the trouble of drying and a second grinding is avoided. Raw bone dust, when acted upon by acid and water, forms a pasty mass which requires time and labor to dry properly. It is undoubtedly better for the farmer who has collected a quantity of raw bones which he desires to convert into superphosphate, to make a pile, allowing them to rest upon rough stones, surrounded with a low wall. This constitutes an extempore furnace, in which, with the aid of wood to kindle, the bones can be burned to whiteness, thereby becoming very brittle, so as to be easily ground to a powder. The loss in organic matter will be a little more than 25 per cent., but this does not detract from the value of the superphosphate which can be made from the bones. If bone charcoal is employed, such as has been used in refineries or laboratories, it is all ready to be acted upon by the acid. Calcined bones can be ground in a common plaster or grist mill. We are using in our laboratory what is known as the Bogardus Mill, which grinds bones, coal, and burnt bones with great facility and rapidity. It is a small mill, made of iron, and requires what is equivalent to a three or four horse power to move it. In preparing superphosphate, use of sulphuric acid or oil of vitriol 50 lbs. to each 150 lbs. of the fine bone. The equivalent of acid, or enough to fully decompose the bone, requires rather more than one pound to two; but there is danger, in imperfect manipulation, that some free or unchanged acid may remain, a result not desirable. It is better to dilute the acid with water by turning into the vessel 3½ gallons, and then adding the 50 lbs. of acid. Into this shovel the 150 lbs. of bone, stirring it constantly with a hoe. If bone charcoal is employed, it will be dry enough and sufficiently fine to apply to the fields as soon as cool. There is much said among manufacturers about superphosphate "going back" after it is made. This means that the soluble phosphate changes by standing into the insoluble condition. We incline to think that this only takes place in the presence of organic substances, and that it is only those mixtures of fish pomace or dried animal matter with superphosphate of lime, that undergo spontaneous change. We are engaged in a series of investigations in our laboratory upon this point, which we trust will throw light upon it. For some purposes for which we use our home-made fertilizers, we add to each 1,500 lbs. of the dissolved bone, 300 lbs. of chloride of potassium, and 200 lbs. of nitrate of soda, thus supplying the potash and nitrogenous elements. We modify the combinations to meet the wants of different crops. But to explain all this fully would require a book, and we pass to other topics.

KAINIT.

We have before referred to this potash salt which comes from the Stassfurth salt mines in Prussia. It is very largely used in England, France, and Germany, in agriculture, and from a careful examination of the statements made respecting it we incline to regard it favorably. Mr. C. D. Hunter, chemist at Mr. Lawson's experimental farm, Blennerhasset, England, has used it with success upon potatoes and other crops, and many others have used it with satisfactory results. Our experiments at the farm with kainit have not been long enough continued to justify confident opinions. Kainit is composed of about 25 per cent. of sulphate of potash, 20 per cent. of sulphate of magnesia, 40 per cent. of chloride of soda or common salt, and 15 per cent. of gypsum and chloride of magnesium. The potash is the most valuable ingredient, and if we estimate the value of that in each ton, we reach the following result: sulphate of potash contains 54.08 per cent. pure potash, 45.92 per cent. sulphuric acid; and therefore 2,000 lbs. of kainit averaging 25 per cent. of sulphate of potash would give 270.4 lbs. of pure potash. Commercial potash contains but 75 per cent. of pure alkali, and hence its cost at present prices is fully 10 cents a pound. The pure alkali therefore in one ton of kainit would be worth about $27.00. The salt, gypsum, and magnesia have considerable value as manurial agents. The salt is largely in excess of the other ingredients, and we fear it may be too large for some soils. Kainit is manifestly a substance worth trying, and since through the efforts of Wm. Grange, Esq., of Baltimore, it is placed within reach of farmers, we hope it will receive extended trial in this country. Mr. Grange offers to supply it at $13.00 the ton, currency, which is a very low price compared with that of some dealers, who have been asking $40.00 the ton. The integrity of the article as furnished by Mr. Grange is guaranteed, each cargo being accompanied by the sworn certificate of Dr. G. L. Ulex, chemist, at Hamburg. We presume farmers can obtain quantities as small as a single ton by addressing Mr. Grange at Baltimore, but of this we are not certain. All desired information may be obtained by addressing him.

ANALYSIS OF SOILS.

MUCH interest is manifested by agriculturists regarding the value of soil analysis, and we are often solicited to express views upon this point. Careful experiment and observation have led us to conclude that less practical or positive knowledge is gained by analysis of soils than many suppose. We entered upon the work ten years

ago with much enthusiasm, and expected to be unerringly guided in our farm operations, by the results attained. It was found that while we had no difficulty in learning the exact ingredients of our soils, we could not ascertain in what states of combination they existed. Many soils examined were found to be quite similar in chemical composition, but they differed widely in their productive powers; and also, soils which were found to contain in rich abundance all the elements of plant nutrition did not grow crops as we had reason to expect. Soil analysis fails to throw light upon the mechanical or physical conditions which have a most important bearing upon crops, and the growth of every kind of plants.

Simple analysis of top-coverings, without taking into account the nature of subsoils, location, mechanical conditions, etc., is not to be relied upon as a certain guide in the management of lands. Nevertheless chemistry, directly and indirectly, affords great aid in soil cultivation, and in some cases soil analysis may be valuable. For instance, if lime or potash be wanting in soils it will inform us of the fact, and we can supply these important substances with great benefit. A single analysis of the soil of a wheat or potato field may show the absence of some one of the elements of food upon which the plant depends, and if it were not supplied the crop would be a failure. Soils come from the rocks, and their character depends upon the nature of the rocks from which they have resulted. Some are rich in potash, others in lime; and a soil rich in one or the other of these ingredients is not benefited by their application. Thus, analysis teaches us how to prevent loss in two ways: loss of crops, by supplying needed plant-food; and loss in using unnecessary manure upon lands where it exists in abundance. It also teaches us that certain lands are naturally barren, and cannot be reclaimed with profit, and that others have soluble salts in such large proportions that they cannot grow crops.

There are a large number of enigmas in soil cultivation which chemistry has thus far failed to explain. It is known, for instance, that superphosphate greatly benefits a turnip field, and yet analysis of the plant reveals the fact that but little phosphoric acid enters the plant; and also, it is probable that potash and other salts may exist in such peculiar combinations in soils as not to be readily detected by chemical tests, as we find that potatoes, which require much potash, will sometimes grow upon soils in which we fail to detect this agent.

This subject is an important and interesting one, but it would require an extended treatise to give it proper consideration.

A VERY GOOD COMPOST.

A gentleman residing at La Grange, Ga., wrote to us some time since, that the following mixture had been used upon the cotton fields of that section with excellent results:—

Nitrate of Soda	40 lbs.
Sulphate of Ammonia	60 "
Muriate of Potash	20 "
Bone Dust	200 "
Gypsum	200 "
Salt	50 "
Soil or Muck	1,430 "
	2,000 lbs.

This mixture embraces quite all the great essentials of plant food, but we think it is too much attenuated. The proportions might be doubled (leaving out half the soil) with advantage, as it would not be so heavy to handle. We would however suggest an improvement in the proportions employed: instead of 60 lbs. of sulphate of ammonia it had better be, for cotton, 100 lbs.; and good, true superphosphate might take the place of the bone dust with advantage. The cotton plant needs the active influence of phosphoric acid to push it forward vigorously. If the planters will combine together and purchase these commercial articles, good and true, at the lowest wholesale rates, and make this compost, they will save the tens of thousands of dollars thrown away upon the factitious mixtures sold so freely in the South.

To Dissolve Ground Bone.—"S. C. S.," Aiken, S. C., asks, What proportion of sulphuric acid is required to dissolve ground bone? 22 lbs. of acid will dissolve 100 lbs. of bone. But the Charleston phosphate is not bone, and contains no animal matter; and a larger proportion of acid is necessary to dissolve it; we do not know the exact quantity, but it can be easily determined on trial; probably 50 lbs.—*American Agriculturist.*

Remarks.—A journal of so high character as the *Agriculturist* ought not to publish an item like the above. It must mislead, and therefore do injury. No amount of acid will *dissolve* ground bone. To liberate the phosphoric acid and form the new combinations which as a whole are called "superphosphate," much more acid is required. How is a farmer to "determine by trial" the amount of acid necessary to "dissolve" the Charleston phosphates? Is he to continue to pour on acid until the phosphates are *dissolved* or placed in solution? Before this is effected he will require more acid than any manufacturer can supply. It would have been much better to have answered the correspondent's inquiry by saying that the writer did not know anything about dissolving bones.

Wild Plants for Hanging Baskets.—Those who have tried to grow the *trailing arbutus* in the parlor have usually failed, but a lady correspondent of the *Horticulturist* has succeeded in doing it for several consecutive seasons. "Early in April," she says, "as soon as the snow was gone, we gathered trailing arbutus, partridge-berry (*Mitchella repens*), winter-green (*Gaultheria procumbens*), ferns and moss, with sometimes a plant of the yellow-blossomed wild strawberry (*Fragaria vesca*). The basket was first lined with soft moss, and then filled with light forest mould. A strong root of fern was planted in the centre, the other plants filled in, and the whole kept well watered. For many weeks the basket was kept gay and fragrant with the successive blooms of the arbutus, and as they disappeared the delicate bells and bright scarlet berries of the *Mitchella*, nestling amid the rich foliage and soft moss, made a thing of beauty the entire season.

The conditions observed were: 1st. To renew the materials of the basket every spring. 2d. To select plants with good roots, growing in light leaf mould, and, in case of the arbutus, to obtain plants plentifully filled with buds. This plant will not form buds in a hanging basket; and, indeed, so far as my observation goes, it will only do so when growing over a rock. 3d. And quite as important as all the other items, the basket was kept well watered and in the shade. No sunshine was ever allowed to strike it, a cool situation near a north window being found the most favorable place for it."

Boston Journal of Chemistry.

BOSTON, APRIL 1, 1872.

HOUSEHOLD ELECTRICITY.

During the extraordinary clear cold weather which prevailed in February and March the electrical phenomena observed in some houses excited much interest. In our own dwelling, for many days, no member of the family could walk across a room and come in contact with a metallic substance without receiving an electrical shock, accompanied with a spark and report. The door knobs, stop-cocks connected with steam radiators, gas-cocks, registers, etc., were so electrically spiteful that they were handled with caution. Our children amused themselves in the evening by lighting the gas with their fingers, and altogether the electrical condition of the atmosphere was quite unusual. In order that this exhibition of household electricity may be witnessed in perfection, it is necessary that the weather be clear and cold, and that the rooms be carpeted with heavy carpets, and these should be insulated by paper mattings beneath. Under these favorable conditions, a person scuffling or even walking across a room becomes so charged with electricity that he can ignite a gas-jet readily, by applying to it the tip of his finger.

Observing this play of one of the mysterious forces of nature, we could not help reflecting upon the fact, that with all our knowledge we to-day know no more of what electricity *is*, than the ancient Romans, Grecians, or Egyptians. It is an agency or force which has never been *seen*, *measured*, or *weighed*, and in *itself* is as illusory, intangible, incomprehensible, as the "stuff that dreams are made of." All we know of it relates to its *effects*, and it is not probable that human knowledge will ever reach beyond this boundary.

It is a force that we have been able to put in harness, and by complying with the conditions under which it acts, we can compel it to serve important ends in benefitting the race. It is probable that at present we understand most of the laws or conditions which govern it, and that we have utilized the agency so far as it is capable of being utilized. Its relations to matter, and to the phenomena of life, are also quite well understood. This being conceded, it is evident that *as yet we are utterly unacquainted with a sufficient number of forces to do the work of the universe.* Every day the student and experimenter is brought face to face with phenomena which he is wholly incompetent to explain, and although electricity is a convenient agency to which to refer everything inexplicable, yet it is a very unsatisfactory pack-horse upon which to crowd our difficulties.

There are many things yet to be learned, and proud as we are and have reason to be of our philosophy, as the ages roll on, what we know to-day will stand comparatively as the science and knowledge of the ancient Romans stand to the great light of the present age.

THE TEA HOUR.

The tea hour, in thousands of happy homes, is the hour of the day looked forward to with most intense delight, as it calls around the table

the members of the household after the various cares and labors of the day are completed, and a season of rest and social intercourse is anticipated. The dining hour is with most people the time when the appetite is craving, and the sense of hunger is apt to beget a considerable amount of impatience or perhaps fretfulness. If there is any hour in the day when the man of business is unamiable or testy under his own roof, it is just before dinner, when he is waiting for the signal which is to summon the family to the dining-room. Children, guided by their quick instincts, seldom ask for favors at such unpropitious moments; and often family pets, the dogs and cats, learn to skulk away into some quiet corner, and wait until the meal has fairly begun, before they venture to intrude themselves into chairs, or come within reach of the paternal boots. Dinner may be called the *business* meal; it is the one which requires the most labor and expense to provide, and it is too apt to be partaken of when the mind is loaded with the business perplexities of the day. In the nature of things it cannot be the season when the family shut themselves in from the outside world, and turn the current of the thoughts upon pleasant themes.

At breakfast there is more or less hurry. The mind, refreshed with sleep, is elastic, confident, eager to encounter the labors and duties which have come with the morning sunlight, and there is little inclination to talk or think of other matters than those which are connected with the work of the day. It must be conceded, that in this country the tea hour is the time, and the tea table the place, for the introduction of topics of conversation which require a forgetfulness of everything that is personal or selfish. It is peculiarly the time and place for social converse upon the wonderful and beautiful things in nature which modern research has so clearly unfolded, and which when understood are so well calculated to make us not only wiser but better.

It is the duty of every parent to introduce at the table topics of conversation such as will interest and improve the minds of the younger members of the family. Every number of the Journal of Chemistry contains essays and items bearing upon the welfare of individuals and communities, and they furnish appropriate subjects for conversation and discipline. There are but few families that will not be made wiser, happier, better, by turning the thoughts upon the interesting facts of science and art as presented from month to month in the pages of this journal.

WONDERS IN THE SUN.

The solar "explosion" or eruption of September 7th, 1871, observed by Professor C. A. Young, and described by him in the Journal of last November, has excited great interest in scientific circles, both in this country and in Europe. The London *Spectator* makes it the theme of an extended article, and says that "it must be regarded as absolutely the most striking phenomenon yet witnessed by observers of the sun." Mr. R. A. Proctor, in the *Popular Science Review*, speaks of it as a "solar outburst the most wonderful by far that has yet been witnessed, and affording highly significant evidence respecting the mighty forces at work in the sun's globe." The *Cornhill Magazine*, in an article on "Meteors," and several other leading English periodicals, refer in language equally emphatic to its imposing character, and its important bearings upon the problems in solar physics that are now engrossing the attention of scientific men throughout the world.

It is clear that this wonderful phenomenon furnishes evidence in favor of the theory that the *corona* of the sun (and we may now consider it settled that it *does* belong exclusively to *the sun*, and is nowise due to an effect of our own atmosphere) is partially caused by solar eruptions. It had been a question whether the range of the forces that produce these eruptions could extend through distances so vast as the coronal rays are seen to reach. Astronomers become familiar with the most stupendous energies exerted on a scale so grand and through spaces so immense that the imagination is wearied in the effort to conceive of them; but here it was necessary to suppose volcanic forces that even an astronomer dared not assume to be possible until he should have some positive proof of their existence. And such proof is furnished by this unprecedented eruption, in which glowing hydrogen was *seen* to rise from a height 100,000 miles above the solar surface to double that height in ten minutes, or with the velocity of 167 miles a second!

And it must be borne in mind that it was *hydrogen*, the lightest of all substances known to us, that was hurled to this inconceivable height with this inconceivable velocity, and *against the resistance of the solar atmosphere*. From its velocity between the limits observed, we can prove by mathematical calculation that its motion was greatly retarded by this resistance. But it is not likely that the erupted matter consisted solely of hydrogen. It was probably accompanied by heavier matter — perhaps the metallic vapors that have been recognized in the "eruption prominences" of the sun — and these would be retarded much less and consequently thrown much farther. "Compared with the heavier erupted matter," as the *Spectator* remarks, "the filmy wisps of hydrogen were but as the smoke from a cannon's mouth compared with the cannon-ball." Knowing the actual velocity of the hydrogen in the upper part of its ascent, we can show that the velocity of heavier matter would probably be so great that portions of it would be hurled away from the sun, never to return.

This remarkable eruption therefore tends to support another recent theory, namely, that *meteors* have their origin in such solar outbursts. This theory is discussed at length in the article from the *Cornhill Magazine* to which we have alluded above (reprinted in the *Living Age* for February 3d), but our limits will not allow us to make more than this passing reference to it here. Mr. Proctor's article in the *Popular Science Review* is reprinted in the *Eclectic* for March.

We may remark incidentally that, while in the majority of cases due credit has been given to the Journal by those who have copied or commented upon Professor Young's communication, the English magazines mentioned above have not deigned to make the proper acknowledgment to our little monthly.

☞ For the Publishers' Notice, etc., heretofore put at the head of the editorial department, the reader is referred to the last page of advertisements.

THE ANXIETIES OF AN INVENTOR.

We have on a former occasion alluded to the exacting and exhausting character of experimental and inventive labor. He who is engaged in planning or executing a new industrial enterprise, especially if it be one involving great expenditure of money, and affecting the interests of many beside himself, never lays down his burden of care and solicitude until his task is successfully consummated. No waking hour is free from anxiety, and no sound and refreshing slumber relieves the wearied brain.

Twenty-two years ago to-day (it is the 5th of March when we write) the first locomotive engine passed through the Britannia Tubular Bridge, which was a new experiment on a grand scale. What an anxious day must that have been for Robert Stephenson! It was then that he won his greatest fame as an engineer. It was, indeed, a great triumph to carry a train through a tubular bridge over the Straits of Menai. The largest arched span that had been previously constructed was only 240 feet, and here rigid iron tubes 460 feet long were stretched in mid air where the tallest ships could sail beneath them. So broken had Stephenson's rest been whilst planning this great enterprise, that when he got the first tube floated, and was satisfied that all was safe, he said, "*Now I shall go to bed!*" But although so far successful, the anxieties connected with the enterprise were not at an end, for the Britannia Bridge, which is now the wonder and marvel of the traveller, had only been commenced; and so exhaustive was the gigantic undertaking, that in referring to it after its completion, Stephenson says: "It was a most anxious and harassing time with me. Often at night-time I would lie tossing about, seeking sleep in vain. The tubes filled my head! I went to bed with them, and got up with them. In the gray of the morning when I looked across the square in which I resided (in London), it seemed an immense distance across to the houses on the opposite side. It was nearly the same length as the span of my tubular bridge!" When the first tube had been floated a friend remarked to him, "This great work has made you ten years older;" to which he replied, "I have not slept sound for three weeks!"

BAD WATER.

As an illustration of the bad character of water often used for domestic purposes, we present the analysis of a specimen taken from a well in Woburn, Mass., which has, we understand, supplied several families during the past year.

The water contained, in each United States gallon, of—

Organic matter	10,783 grains.
Inorganic "	62,713 "
Total solid contents	73,496 grains.

This water was largely contaminated with nitrates, and afforded evidence that it was receiving from some source animal and vegetable *débris* in unusual quantities. A well water recently sent to us from Andover, Mass., for analysis, furnished results nearly as unsatisfactory as the above, and almost every day we have occasion to point out to heads of families the fact that the water used is the true source of ailments which for a long time puzzled the medical attendant.

ZINC POISONING.

Having clearly and persistently pointed out the dangerous nature of the galvanized iron pipes when used for water conduction, during the past year, we have not alluded to the subject for some months. The poisoning of individuals and families through this agency still continues in some sections, and we are led to raise another note of warning. We hear of a family of four persons in Portsmouth, N. H., made very ill by using water drawn through the zinc-covered pipes. Dr. Jackson examined some of this water, and found six grains of oxide of zinc in the gallon. Hundreds have suffered to a greater or less extent from zinc-impregnated water, and legislative enactment should forbid the use of the galvanized pipes if there is no other way of reaching this desirable end.

EDITORIAL NOTES.

How Gunpowder is Exploded by an Electric Current. — One of our correspondents is puzzled to understand how a current of electricity conducted by a wire can be made to explode gunpowder at a distance, when a telegraphic wire is not perceptibly heated by the passage of the fluid, and will not ignite gunpowder placed in contact with it. We may receive the *spark* from an electrical machine or a Leyden jar in the midst of gunpowder without igniting it. In fact, experimenters sometimes find it no easy thing to get up an explosion in that way. In using galvanic electricity for the purpose, advantage is taken of the fact that if the current is sent through a *fine* wire of *poorly* conducting metal, the resistance it meets causes it to ignite the wire. Good conducting wires are therefore used for conveying the current to the gunpowder, and fine wire is used for connecting these within the cartridge, a common form of which is shown in the figure. It consists of a tin tube filled with gunpowder, and tightly closed at both ends. Two copper wires, properly insulated, pass into it, and are connected within by a fine steel wire soldered to each of them. When the current is sent through the wires this fine wire is burnt up, and thus the powder is ignited. The copper wires can be refitted with a fresh piece of steel wire, and used again and again.

Following the Sun Round the World. — The journey round the world is scarcely more of an undertaking at the present time than a trip to Europe was a few years ago. "The actual travelling time," as Rev. Dr. Prime states in the preface to his "Around the World," just published by the Harpers, "has been reduced to seventy-five days, distributed as follows: From New York to San Francisco, by rail, six days; from San Francisco to Yokohama and Hong Kong, by steamship, twenty-seven days; from Hong Kong to Calcutta, by steamship, twelve days; from Calcutta to Bombay, *via* Allahabad, by continuous rail, a journey of 1,450 miles through the heart of India, three days; from Bombay to Suez, by steamship, eleven days; from Suez to Paris or London, by steamship and rail, six days; from London to New York, ten days." One would not like to spend less than six months on the tour, which if his plans were carefully laid out in advance would enable him to glance at the chief points of interest *en route.* What he can accomplish if he takes a year for the journey, Dr. Prime's book will show; and there are advantages in devoting just that period to the tour. By starting at the right time (about the first of August), and going westward with the sun, "the traveller will be in each country, and on every sea, at the most favorable season; whereas a longer period would inevitably bring him into some oriental region in midsummer, when the heat is almost intolerable even for residents, or among the typhoons and cyclones of the tropical seas." In this way the circuit of the earth may be made as safely and comfortably as an ordinary summer excursion to Europe. California, Japan, China, India, Egypt, and Palestine, may thus be visited in turn, and time enough will remain for a run through Italy, Switzerland, Germany, France, and the British Isles, before the year has elapsed.

Anæsthetics in the Slaughter-House. — Now that so much is being done to prevent man's inhumanity to the brute subjects of the realm which he rules as "lord of creation," it is not to be wondered at that measures are proposed to reform the long established barbarous methods of slaughtering them for purposes of food. There can be no doubt that the suffering inflicted upon animals in killing them is not only great, but wholly unnecessary. An interesting paper on this subject was lately read by Dr. Richardson before the Medical Society of London, and the matter will probably be taken up by the Society for the Prevention of Cruelty to Animals. Although some animals appear to witness the death of others without emotion, yet this is not universally the case, and the pig especially has a great fear of impending death. Dr. Richardson has discovered an anæsthetic composed of coal gas combined with bichloride of methylene, which he recommends for general use in slaughter-houses. It is simple, easy, and safe in application; it does not interfere with the flow of blood or in any way affect the quality of the meat. He has also invented an apparatus consisting of a tin reservoir made to hang on a nail in the wall of the slaughter-house, and intended to contain the bichloride of methylene. To this reservoir two india-rubber tubes are attached, one to be connected with a common gas jet, the other terminating in a tin funnel large enough to receive the nose of a sheep and capable of being fastened like a muzzle on the head. The muzzle being placed, the tap of the gas is turned, and the gas bubbling through the bichloride is breathed by the animal. In a minute perfect insensibility to pain is produced, and animals breathe the gas quietly without struggling or apparent dread. For large slaughter-houses Dr. Richardson has designed a sort of passage divided into chambers, the central chamber being filled with the mixed vapor; mere passage through it will render the animal insensitive to the knife.

A Royal Clothing Factory. — A report by Mr. Redgrave, the Inspector of Factories, recently issued, gives an interesting account of the Royal clothing factory at Pimlico, at which clothing is made for the army. The separate pieces of the garments are chalked out in the usual manner upon the surface of the cloth, and the piece of cloth with the pattern so chalked upon it is placed above seventy-nine similar pieces of cloth, when the whole are cut out at one operation by a band knife resembling a band saw, but without teeth. The sewing of the parts together, to make garments, is performed partly by sewing-machines and partly by hand. The seams, after having been sewn, are ironed in the usual manner; but the irons are heated by jets of gas, and the iron is pressed down upon the ironing board by a pedal, to reduce the labor of the operator. The work is paid for by the piece. The price paid for making a tunic is 3*s.* 4*d.*, and for making a pair of trowsers is 1*s.* A woman can make about one tunic per day, or four pairs of trowsers.

ATOMS.

The corn raised by the Iowa Agricultural College costs only twice its market value; which is quite creditable for one of those institutions, and better than their average achievement. — A wire rope, six thousand yards long (about three miles and a half) and capable of bearing a strain of fifty tons, has been made for drawing trains through a tunnel on the North British Railway, in Scotland. — The *American Practitioner* says that "Fireside Science" is a book that "ought to be found in every family circle where there are young minds to be interested in the study of physical science;" and the *Philadelphia Medical and Surgical Reporter* remarks that "it is particularly adapted to the instruction and entertainment of the younger members of the family, though it is by no means too simple and commonplace to instruct older and well-read persons." — We see by advertisements in English papers that "the Great Northern Telegraph Company now forward messages to Hong Kong, Shanghai, and Nagasaki, by way of Russia, at the uniform rate of £4 8*s.* per message of twenty words;" so that a message may now be sent from San Francisco across this continent and the Atlantic, and then by the above route to China, as promptly as a few years ago it could have been transmitted from Boston to Chicago. — It has been rather chilly out in Montana, where the thermometer at Fort Benton is reported to have gone down to 59° below zero. — In six coal counties in Pennsylvania, last year, 822 persons were killed and injured; leaving 220 widows and more than 400 orphans. — The Supreme Court of Maine has decided that an oyster is a fish; a zoölogical "ruling" to which exceptions are likely to be taken in scientific if not in legal circles. — Those who have travelled in foreign lands come home and lecture on what they have seen; and now a man who has been in the Wisconsin State Prison is going to give a course of three lectures on "Our Prisons, their Uses and Abuses." — Bone-dust is occasionally adulterated with the turnings and raspings of vegetable ivory (*Phytelephas macrocarpa*); a fraud readily detected, as the spurious matter leaves a much smaller amount of ash than bone-dust, and lacks phosphate of lime. — Some of the agricultural papers are wondering at the fact that "a plant may be raised from a seed in a flower-pot, receiving no nourishment but pure water, and yet far exceed in weight all the soil in which it grew;" as if there were anything strange in that, when the merest smattering of botany suffices to show that plants draw their nutriment largely from the air. — Iron filings are sometimes mixed with the pulp in making wrapping-paper; a fraud on the purchaser, which is made up to *him* when the paper is weighed along with the articles he puts up in it. — The *Literary World*, advertised in our last number, is invaluable to those who would keep track of what is going on in "the literary world," and everybody that reads a specimen number is pretty certain to become a permanent subscriber. — The man that originated the Cardiff giant has retired from business with a snug fortune; which illustrates the advantages of having a natural turn for geological pursuits. — A stationary engine of three thousand horse-power, said to be the largest in the world, has just been started up in the Lehigh zinc works, Friedensville, Pa. — The metric system has been legalized by act of Congress, but it has not been introduced into New Jersey, where an editor, who read in the cable dispatches that "Bazaine has moved twenty kilometers out of Metz," sat down and wrote an editorial, in which he said he was delighted to hear that all the kilometers had been removed, and that the innocent people of Metz were no longer endangered by the presence of those horrible engines of war; and then he went on to describe some experiments made with kilometers in the Crimea, in which one of them exploded and blew a frigate out of water. — The Massachusetts *Teacher*, which a critic not long ago unfeelingly called "a seedy magazine," has greatly improved this year, both outwardly and inwardly, and is now one of the best educational journals in

the country. — The *Connecticut Common School Journal*, which has passed into the hands of those enterprising publishers, Chatfield & Co. of New Haven, begins the volume for 1872 in new and enlarged form, and is every way better than of old. — Forty barrels of "pop-corn" have been shipped from Illinois to England, where the article is a novel luxury. — An English druggist received the following: "please sur if you wold hif you would send me up some stofe for a child aboit to years old she is verrey bad and had to cunvelesons fits and she is cutting her duble teeth it tis whate you call the dum fever."

POISONOUS PAPER COLLARS. — A clergyman residing in Sussex County, Delaware, having been greatly troubled with numbness in his limbs, and other symptoms which led his physician to suspect lead poisoning, sent to us the ash resulting from the combustion of one of the paper collars worn by him, and we found upon analysis that it contained carbonate of lead in considerable quantity. This dangerous substance is used in the glazing of some cuffs and collars made of paper, and when the hands and neck perspire or any abrasion of the skin occurs, the lead is absorbed and poisoning results. The brand of collars containing the lead was represented to be what is known as the "Dickens" collars.

A DISTINGUISHED gentleman in Massachusetts writes us as follows regarding the JOURNAL: —

"Your publication is so universally pronounced excellent, that words of commendation may seem stale to you. But you must allow us readers the pleasure of saying that few papers or magazines of any kind convey so much desirable and practicable knowledge as the JOURNAL OF CHEMISTRY."

LITERARY NOTES.

MESSRS. SCRIBNER, ARMSTRONG, & CO., successors to the well known house of Chas. Scribner & Co., have begun another popular series of books entitled "The Illustrated Library of Travel and Adventure." It opens well with Bayard Taylor's *Japan*, an admirable description of a land in which everybody is interested just now, on account of the visit of the Japanese embassy to this country. If the succeeding volumes are not inferior to this, the success of the new series is assured.

The same publishers have issued Vol. II. of *Curtius's History of Greece*, which we have before commended. The revision of the translation by Prof. Packard, of Princeton, makes this edition as much better than the English as it is cheaper. Vol. III., completing the Peloponnesian War, will soon be ready, and will contain a full Index to the three volumes, — another good feature of this edition.

The Harpers have just published *Around the World*, by E. D. G. Prime, D. D., the record of travels through many lands and over many seas — a book to which we have alluded elsewhere; *Paul's First Epistle to the Corinthians*, by Rev. Dr. Barnes, another volume of the revised edition of his "Biblical Commentaries;" and *Twenty Years Ago*, from the Journal of a Girl in her teens, edited by the author of "John Halifax," and much the best thing that has yet appeared in her series of "Books for Girls." Mr. Rolfe's edition of Shakespeare's *Julius Cæsar* will be ready by the first of April; and in reply to many inquiries from teachers and others, we would say that this play, with the three previously published, will then be bound in one volume for those who prefer them in that form. This book, as well as the others mentioned above, may be found at Noyes, Holmes, & Co.'s.

Under the title of *Half-hour Recreations in Popular Science*, Messrs. Lee & Shepard, of Boston, propose a monthly series of papers selected from the works of eminent scientific writers of the day; and they have issued a sample number containing Mr. R. A. Proctor's "Strange Discoveries respecting the Aurora," and "Recent Solar Researches." Single numbers are to be furnished at 25 cents; twelve monthly numbers, postpaid, for $2.50. The plan is a good one, and we hope it may be carried out.

☞ WE have received subscriptions from the following persons; but as they do not give their post-office address, we are unable to send the paper until we hear from them again: —

JOHN GILMORE,
DR. DA CAMARA,
J. W. MCCLEARY,
P. MOULTON,
GEO. C. WILSON.

Medicine.

DOCTORS IN COUNCIL.

THE peculiar duties of physicians would not seem to be favorable for the development of oratorical powers, or for acquiring skill in debate; but we have observed in the meetings of the Councillors of the Massachusetts Medical Society, during the past three years, that these accomplishments were by no means wanting. We do not believe that any class of men can be brought together in deliberative assembly, who transact business with more directness, accuracy, and despatch, than this body of intelligent medical gentlemen. And in debate, we have been surprised at the clearness, force, and eloquence which these watchers at the bedside of the sick and suffering are capable of exhibiting. Parliamentary rules are better observed and enforced, nice points more quickly seen and understood, and personalities more completely avoided in their meetings, than in assemblies of lawyers, politicians, schoolmasters, or legislators. We believe this is generally true of all meetings and assemblages of educated physicians in this country and Europe. We must not be understood as intimating that doctors never disagree, or indulge in sharp controversies when met together, for such intimations would certainly excite a smile upon the countenance of every reader; but we do say that physicians manage and conduct public meetings with unusual tact and propriety, and show in debate a quiet, unostentatious force and directness, worthy of imitation in all classes of public speakers.

The school in which physicians are educated is eminently a practical one, and is as unlike that in which lawyers and politicians are reared, as anything can well be. They are able to study human beings under circumstances not possible to others, and to obtain an insight into motives and character, when all masks are thrown aside. They are compelled to meet exigencies, and give succor in hours of anguish, and in times of peril. Hence, they learn to act promptly, decidedly; the judgment is quickened, the moral force strengthened, the sensibilities aroused.

This kind of education when brought into deliberative bodies has its influence upon the proceedings, and gives to them the practical directness and business-like air to which we have alluded. We never heard a physician make a *long* speech, and doubt if it is possible for one who has been long in active medical practice to "talk against time," upon any occasion. The essays read at medical meetings are sometimes long and heavy, but they are oftener brief and interesting. Altogether, we have a high opinion of the educated, cultivated medical man, not only when his talents are displayed in the sick-room, but when met for deliberation, and the discussion of professional and public affairs.

A REMEDY FOR SMALL-POX.

FOREIGN medical circles appear to be somewhat excited over the alleged discovery of a specific for small-pox, which is said to have been tried in a Berlin hospital by Dr. Zuelzer with remarkable success. This new remedy is *xylol*, also known under the euphonious synonyms of xylyl-hydrogen, xylen, xylenyl-hydrogen, and dimethylbenzol, among which the reader is free to choose the appellation that is most acceptable to his own ear or tongue. It is one of the products of the distillation of coal-tar oil, is homologous with benzol and toluol, and possesses a specific gravity of 0.8309. It was first found by Cahours, in 1850, among the distillation products of wood. By the addition of water to crude pyroxylic spirit xylol is separated; then it is agitated with sulphuric acid. After several hours' standing, a mixture consisting of xylol and other hydrocarbons is found floating over a brown liquid. This is first washed with a solution of hydrate of potash, afterwards with water, then dried over chloride of calcium and anhydrous phosphoric acid, and afterwards subjected to distillation. Xylol is then found in the liquid running over at 120° to 130° C. It is best administered in form of oil emulsion with cinnamon syrup, or in gelatine capsules. The dose for an adult is ten to fifteen drops, for children three to five drops, hourly or every three hours. Dr. Zuelzer expressly remarks, that the good effects of xylol are only apparent when it is perfectly pure and entirely free from toluol and benzol.

Pure xylol can be obtained of Messrs. J. R. Nichols & Co., chemists, of this city.

OVERTAXING THE MINDS OF CHILDREN.

THE *New York Medical Journal*, for March, gives some extracts from a lecture on "Physical Disease from Mental Strain," by Dr. Richardson, of London. After treating of the ailments caused by excessive mental labor in various classes of adult brain-workers, he considers the injury done to the young by overtaxing their minds in school. The extent of this injury, as he remarks, varies according to the kind and character of the work. In the very young it gives rise to direct disease of the brain, to deposit of tubercle, if there be any predisposition to that disease, to convulsive attacks, or even to epilepsy. In less extreme cases, it causes simple weakness and exhaustion of the mind, with irregularity of power. The child may grow up with a memory overburdened with technicalities, and rendered almost incapable of the acquisition of other knowledge; and often the brain, owing to the labor put upon it, becomes too soon mature, so that in manhood it is merely a large child's brain, very wonderful in a child, and equally ridiculous in a man or woman. The development in an excessive degree of one particular faculty is also a common cause of feebleness.

As an illustration of the danger of constantly forcing a single faculty, he tells the story of a boy whose originally good memory was cultivated to such a degree that he could learn fifty lines of "Paradise Lost" at a single reading. On going from school to the University he was beaten by every fellow-student in the learning of detailed and detached facts. For a long time he made mistakes that were most annoying; he was unable, for instance, to cast up accurately any column of figures, he forgot dates, he ran over or under important appointments, misnamed authors in speaking of works of art or letters, and, in reasoning, his want of analytical power was painfully felt. It took him full ten long years to unlearn his wonderful technical art.

"For the reasons given," says Dr. Richardson, "I have always persistently opposed the special prize system in schools. A teacher, with some experience of results of teaching, I can recall no single instance in which noted prize-men *in early youth* bore away more than other men the prizes, that is to say, the successes, of after-life. I have, however, many, many times known the successful prize-man in the class the least successful afterward, and as often have known the most ordinary youths, in class, come out as the best men in life. Overwork in the child and in the student defeats its own object; it does not develop the powerful brain so necessary for the man: for life is ever a new and great lesson, and some young brain must be left free for the reception of lesson on lesson. Of this there need be no doubt, and there we may leave the first and leading fact. But the danger of overwork is, unfortunately, not confined to the brain; it extends to the body as a whole. When the brain is overworked in the growing child, however well the child may be fed, and clothed, and cared for, there will be overwaste of substance in proportion to the overwork. There will be stunted growth, and the formation of a bad physical body."

POISONOUS PAPER HANGINGS.

We long ago warned our readers against arsenical wall-papers, but we have recently seen it stated in the journals of the day, that, except in the case of a certain bright green, arsenic is rarely, if ever, used in coloring these papers. It appears, however, that the English "Social Science Association" takes the contrary ground, and in their "Transactions" for 1871, a paper on the subject is printed, from which we make the following extract:—

The fact that nearly all the green coloring now in use is arsenical has been indisputably proved by eminent analysts. Specimens can be produced of pale green papers containing six, nine, and even fourteen grains of arsenic to the square foot, and papers containing only a leaf or line of green in the pattern are arsenical and injurious. Yet such papers are to be seen everywhere; in royal palaces, in the mansions of our nobles and gentry, in lodging-houses, and the homes of the middle and industrial classes in town and country. Medical men have these poisonous papers on their walls, and suffer from them unawares. Arsenic was first employed in the manufacture of wall-papers about the beginning of this century, and its use has been on the increase year after year up to the present time. If we cover our walls with a poison which is not only deadly but volatile, can we wonder at deterioration of health? My own experience of the danger of arsenical wall-papers extends over a period of fourteen years, during which my entire household, numbering fourteen persons, suffered severely. But now follows an important point, proving that arsenic is not confined to green coloring, as supposed, but is used in papers of all colors, and even in white. Our papers containing green were replaced with others totally devoid of green, but in a few months' time many alarming symptoms reappeared. Suspecting arsenic again, I had all these papers analyzed, and arsenic was found in the paper of every bedroom in the house, though not one contained even a speck of green. On removing these papers, and coloring the walls with whiting and size, tinted with safe colors, relief soon followed, and health has since steadily improved. It often happens that dangerous arsenic papers are concealed underneath harmless ones, owing to the pernicious custom of putting one paper over another. A very severe case of poisoning by this means has recently come under my notice. Many of the pigments now in use appear to contain arsenic; therefore, in substituting paint or wash for paper, it is important to know of what the colors are composed. There is, I am told, a "new blue" used for coloring walls, which contains arsenic, and the green distemper wash so often used instead of paint is almost invariably arsenical; being totally unglazed, it is all the more rapidly injurious. But the gaseous exhalations of arsenic have been found dangerous, both from glazed papers and oil paint, as was proved at Munich in 1860. The Prussian Government, recognizing the danger, "forbid the use of arsenic in any colors, whether distemper or oil, for indoor work." Yet in this country arsenic paint is freely used on the walls of our rooms, and on Venetian blinds; the green paint used for these latter articles containing about seventy-five per cent. of arsenic.

[The above article was in type before we had seen the new Report of the State Board of Health, which devotes considerable space to this subject. We also see by recent foreign journals that arsenic is largely used in the coloring of *carpets*, both in greens and in *reds;* which is especially dangerous to health, since the wear to which carpets, are exposed promotes the diffusion of the poison in the air.]

PHOSPHORUS FOR SLEEPLESSNESS.

Major A. B., aged about 40 years, served three years in the late war. Being very energetic and trustworthy, his labors were arduous and exhaustive. On his return home he resumed the duties of his trade — that of a carpenter. Engaging in building a hot-house, he was exposed to the sun's heat under glass in the summer time. This exposure was followed by symptoms of disturbance of the nervous system, evincing a loss of nerve force. Naturally of a cool temper, he became excitable. The mathematics of his business became very troublesome, and he found it very difficult to cast accounts or make calculations. His steps were rapid and his manner nervous. There was but little excitement of the pulse; appetite fair; bowels regular. Sleeplessness was the most prominent and perplexing symptom.

Chloral hydrate, bromide of potassium, opium, sulphate of morphia, and valerianate of morphia, were successively tried without avail.

Finally, reasoning that here was a case in which there was a loss of nerve force, and knowing that phosphorus was a most important nerve food, I concluded to put him on its use. He took one fiftieth of a grain thrice daily in pill form. In a few days he slept as well as ever, and discontinuing the pills has since enjoyed his natural sleep.

Post hoc propter hoc is not always a reliable guide. Still, as I have witnessed the calmant and hypnotic effects of phosphorus in other cases, I am disposed to attribute the result in this case to the agent employed. As phosphorus is an irritant poison, great caution should be observed in its employment. None but the right preparation should ever be used, and then only under the direction and advice of a competent and regularly educated physician.

Woburn, Mass.

DISSECTING ANEURISM OF THE AORTA.

Mrs. N. P., aged sixty-eight years. Previous health apparently good, with the exception of slight rheumatic pains and lameness. Was heard to fall from her bed about five o'clock on the morning of February 18. Placed back in bed at once. I was immediately summoned, arriving between six and seven o'clock. Found her tossing about in bed, skin cold, with clammy sweat, pulse feeble, pupils natural; no paralysis, no clutching at any part of body or bedclothes; constantly repeating, "O Lord, O Lord." Could not be made to answer questions, although apparently conscious, as she resisted the introduction of anything into her mouth, with "I beg, I beg" — indistinctly uttered. I was unable to make a diagnosis, and told the family I did not know what was the matter with her, and asked counsel — expressing the opinion, however, that it was of no use, as I considered her dying. Tossing became less and less, coldness continued, all articulate expression ceased, and she died about eleven o'clock same morning, about six hours after being found in the "fit."

In studying her case before death, I had excluded cerebral and pulmonary apoplexy and congestion, aneurism, embolus, cardiac lesions, etc., etc. The question then was: "What was the cause of death?" Permission to examine the body was obtained, and I found a large aneurismal sac ruptured just at origin of aorta, *within cavity of pericardium*, which was, of course, full of blood; no escape of blood into mediastinum. But what renders this case doubly interesting is the fact that the aneurism was what is known as the *dissecting* aneurism — the rupture of the middle two coats being *transverse* and near the origin of the innominata — *dissecting backwards towards the heart.* There was extensive atheromatous and calcareous degeneration of the arch of aorta.

Otisco, N. Y., *March 1st*, 1872.

THERAPEUTICS A HUNDRED YEARS AGO.

The following extract is from Prof. Silliman's "Century of Medicine and Chemistry," noticed in the last number of the Journal: —

"If any one yet desires to ask what the century of chemistry now closing has done for therapeutic medicine, let him take up any formulary of a century old, and look for almost any of the more familiar articles which form the staple of medical practice to-day. He will find set forth in the pharmacopœias of a century agone, with the greatest prominence, such simples and carminatives as balsam of tolu, syrup of marsh mallow, camphor, red coral, Castile soap, ginger, wormwood, James's powder, musk, mace, mummy, album græcum, powdered spiders, viper, millipedes, stomachic tincture, and aqua pura. Of the more potent medicines then known but little use seems to have been made. Iron and its salts, opium, mercury, jalap, and rhubarb were comparatively rare medicines. Peruvian bark finds its place among astringents, in which category fall also calomel and rhubarb. Burnt sponge is used as an alterative, in all innocence of iodine, which was as yet unknown for more than a generation. Alcohol seems to have been used chiefly for tinctures, and there is no class known as tonics. If we examine the prescriptions, it is difficult to say whether a feeling of amusement or disgust at the utter empiricism evinced is uppermost. Viper broth and spermaceti for consumption; oak-bark and gall-nuts for diabetes; musk, decoction of intestines of fowl, red coral, burnt rhubarb, chalk, etc., for diarrhea; tartar-emetic for hooping-cough; calomel and sulphur ointment for itch; are a few examples of the therapeutics of the leading physicians of London a century since. Not to do these worthy men the injustice to suppose that they dealt only in such extreme simples, it must be remembered that there was one form of iron which was an unfailing *vade mecum* and cure-all with them, and that was the *lancet*, with which they made their practice truly heroic."

MEDICAL MEMORANDA.

Glycerine in Putrid Sore Throat. — Dr. J D. Palmer, in the *Journal of Pharmacy*, says: "I have found this an invaluable remedy in putrid sore throat, as well as in many other affections. Not long since a case occurred in which its healing properties were fully tested. The patient, a little girl, seven years of age, had been suffering several days before I saw her, and the various remedies employed

had made no impression on the disease. As it was with great difficulty and pain she swallowed, and her pulse being very weak and quick, it was important that the remedy adopted should possess healing, nourishing, and antiseptic properties; and glycerine possessing these properties, was administered in teaspoonful doses every six hours. The first dose caused some smarting, the second less, and before giving the third there was obvious improvement. The case was dismissed in three days."

CUNDURANGO IN THE ENGLISH MARKET. — The London *Chemist and Druggist* says: "Cundurango, which was lately described by an enthusiastic American writer, as 'the brightest jewel in the crown of Ecuador,' is decidedly losing its lustre here. This much-vaunted remedy for cancer cannot now command a bid of five shillings a pound, although but a short time since forty shillings was paid for a parcel at public auction, and it has been disposed of in America at the extravagant price of twenty-five dollars per pound. Three bales were offered at the London sales on the 7th inst., and were bought in, amid derisive remarks, at five shillings per pound. How have the mighty fallen!"

COLLODION IN CHILBLAINS. — Dr. C. Green, in the *Buffalo Medical Journal*, states that he has used collodion in chilblains with the most decided success. In one case the patient had her feet for a time exposed to severe cold, which produced erythematous inflammation of several of the small toes. They were swollen, red, tender, and itching. He completely enveloped them in a thick coating of collodion, and the contraction which took place on its drying produced so much compression of the vessels that the toes were as pallid as frozen ones. The pain and itching were relieved, and in twenty-four hours these members were nearly well. He has cured pernio of the heel also with this article.

FROZEN BEEF ESSENCE. — Dr. H. B. Hare (*Philadelphia Medical Journal*) writes that, in a case of scarlet fever in a child, the patient could not be induced to swallow the beef-tea which his condition required. As he took ice with avidity, the father suggested that if the beef-tea were frozen he might then be induced to take it in that form. The suggestion was carried out, and the child took the frozen beef tea readily. This expedient may in many cases be advantageously adopted.

GLYCERIZED COTTON FOR DRESSING WOUNDS. — The *Journal de Pharmacie* states that Professor Gubler, at a recent meeting of the Academy of Medicine, exhibited specimens of wadding prepared by saturating it with a certain quantity of glycerine, which he had found to render it permeable to all medicinal liquids, without causing it to lose any of its suppleness and lightness. He suggested that in this state it might prove a useful substitute for charpie, in the event of a scarcity of that article. Dr. Delaborde has already employed it with advantage. In order to prepare this dressing, it is only necessary to pour a small quantity of glycerine over the square sheet of wadding, and afterwards express it as strongly as possible.

NEW METHOD TO DETERMINE THE ALKALOIDS IN PERUVIAN BARKS.

IN testing Peruvian barks, it is not of so much value to the manufacturer to know how much alkaloid they contain as to know how much of sulphate of quinia they will yield.

On trying the different methods recommended, not one of them was found to meet all requirements, whereas the one used by Carles leaves nothing to wish. 20 grm. of the bark, in fine powder, are weighed off, rubbed in a mortar with 8 grm. hydrate of lime, previously mixed with 35 grm. of water, the whole allowed to dry upon a plate by a gentle heat, then rubbed fine, transferred into a glass tube, closed below with lint, and exhausted by means of chloroform; of the latter about 150 grm. suffice. The end of this operation is known when the drops evaporated upon a saucer leave no residue; or one which, when mixed with dilute sulphuric acid, chlorine-water, and liquor ammoniæ in succession, will not assume a green color. If no chloroform shall be lost it may be displaced by water. When the last traces of chloroform have been driven off from the remaining powder, it is kneaded several times with small portions of a ten per cent. solution of dilute sulphuric acid — 10 to 12 cc. of acid are sufficient. The united liquors, put upon a dampened filter, pass through colorless, leaving resinous particles behind. The filtrate is raised to boiling, and so much of ammonia added that a slight acidity prevails. Soon after the quinine crystallizes; collected upon a double filter, the adhering mother-liquor removed by a few drops of water, pressed, dried between paper and weighed. (It is preferable to dry at 100°, but then the twelve per cent. of water which is lost by this operation has to be added when weighing. The salt then contains 75 per cent. of quinine.) The other alkaloids remain in the mother-liquor, and may be obtained by precipitation.

This method always gives satisfactory results. It requires but a few hours' time; is simple, for all the quinine is obtained at once as white sulphate, and the other alkaloids perfectly colorless. Lastly, it is also very effective, for the same bark gave a larger quantity by this process than by that of Rabourdin and that of Maitre, as follows:

From 20 grm. of a cortex chinæ regius were obtained, —

According to Rabourdin	23.00 sulphate.
" Maitre	22.30. "
" Carles	26.55 "

From 20 grm. of another bark were obtained, —

According to Rabourdin	29.50 sulphate.
" Maitre	26.75 "
" Carles	31.25 "

As strychnia and brucia are soluble in chloroform, this method might, perhaps, also be used to determine the alkaloids of the strychnæ. — *Wittstein's Vierteljahrschrift.*

TANNIN AND GLYCERINE.

TANNIC acid is frequently prescribed in concentrated solution with glycerine; but tannin, commercially obtained, possesses various impurities, which either remain as insoluble turbidity or discolor the solution. Firstly, a green resinous coloring matter, insoluble in water but soluble in strong alcohol and glycerine, invariably occurs. This contamination results from the solvent action of the ether in the original process of extracting the tannin. Secondly, metallic chips of copper, iron, etc., from the vessels in which the tannin was dried, are never absent.

A concentrated solution of tannin is nearly indispensable among the requisites of the prescription department. An aqueous solution, however concentrated it may be, will spoil. An alcoholic solution is often objectionable, but an aqueous solution, containing glycerine, can be utilized on most occasions.

This solution is best adjusted by weight; it is perfectly stable, clear, and transparent, and contains one troy ounce of tannic acid in two troy ounces of the solution, that is, half tannin by weight. The solvent is the other half, or $\frac{1}{4}$ each by weight of glycerine and water. More than this proportion of glycerine cannot be used to advantage, as the liquid becomes too thick to pour conveniently. This solution cannot be prepared, however, by directly combining the three ingredients, as the impurities must first be removed; and the only preliminary solvent for this purpose, which the writer has found to answer perfectly, is a mixture of equal measures of strong alcohol and water. A very concentrated solution, in the proportion of two parts of liquid to one of tannin, can be formed with the aid of heat, which filters with the greatest facility, leaving the resinous coloring matter and the metals untouched.

Alcohol alone, in the proportion of four to one of tannin, would not filter well. Water, in the proportion of at least four to one of tannin, would not filter even as rapidly as the solution with alcohol; and whilst the alcoholic solution becomes turbid with water, the aqueous solution never became clear from the first, and moreover was always much darkened by the metallic impurities forming colored soluble tannates. The preliminary solvent and permanent solvent above proposed are therefore the only available ones. These form a light green, thin syrupy solution, miscible with glycerine and water in all proportions without losing their brightness, and forming in a more dilute condition colorless solutions.

From these observations the following formula is deduced. Take of —

Tannin	8 troy ounces.
Glycerine	4 " "
Strong Alcohol	8 fluid "
Water	8 " "

Mix the alcohol and water; add the tannin and apply heat until the tannin has dissolved. Filter hot, then add the glycerine, and evaporate by a careful heat until the solution weighs 16 troy ounces. — *The Pharmacist.*

SELECTED FORMULÆ.

FOR WHOOPING COUGH. — The *Georgia Medical Companion* commends the following as "safe, pleasant, and effective": —

℞	Argenti Ioduret	gr. x.
	Sacch. Alb.	gr. lxx.
	Pulv. G. Tragacanth	gr. viii or x. — M.

Rub well together, moisten with a few drops of water, make pill mass, and divide into 80 pills. Each pill will contain one eighth of a grain of the salt.

S. — To a child 2 or 3 years old, one pill 3 to 5 times a day. To children 6 to 10 years old, 2 pills at a dose.

IODIDE OF STARCH POULTICE. — The following is from the same authority: Take two ounces of starch and mix with six ounces of boiling water to form a jelly, then add, before cold, half an ounce of tincture of iodine. The poultice is now ready for use. It is recommended for sloughing sores, etc.

STIMULATING EXPECTORANT — Recommended by Tanner as useful in pulmonary affections of children, when it is desired to give tartar emetic without producing depression:

℞	Vini Antimon.	f. dr. i.
	Spts. Ammo. Aromat.	f. dr. iss.
	Syr. Tolutani,	f. dr. i.
	Tr. Camph. Comp.	f. dr. ij.
	Aq. Camph.	f. oz. iss. — M.

S. — One or two teaspoonfuls every third or fourth hour.

CARBOLIZED GARGLE FOR DIPHTHERIA. — Carbolic acid, 20 minims; acetic acid, ʒss.; honey, tincture of myrrh, each f.ʒij.; water, to f.℥vj. The acids to be shaken together well before the other ingredients are added.

CHLORIDE OF POTASSIUM. — Dr. Lander has substituted the chloride for the bromide of potassium in the treatment of epileptics with a success which he declares to be identical. He begins with smaller doses; but doses of 75 to 105 grains daily have been borne without inconvenience for months in succession. He states that it is more active, one sixth of the price, and without the inconvenient secondary effects of bromide of potassium. He believes that, in the stomach, bromide is converted into chloride of potassium; and that, for many reasons, it is desirable to administer it at once in that form. — *Philadelphia Med. and Surg. Reporter.*

Familiar Science.

ZINC MINING AND MANUFACTURES.

Not many years ago Mr. C. W. Roepper, of Bethlehem, Pa., in his rambles over the mountains in that locality, chanced to discover some zinc ores at the little village of Friedensville, about four miles from Bethlehem. As a result of this discovery large zinc works have arisen within the last twenty years at that town, and the working of zinc mines, and the manufacture of the oxide of zinc and other products, has become an immense industry. A visit to these mines and works, not long ago, afforded opportunity to learn much that was of interest to ourselves, and doubtless will be to our readers.

The mines at Bethlehem were long worked as open quarries, the supply of ore being abundant and near the surface. In this way a huge opening was excavated, but as the depth increased and the ore was not so rich, they abandoned the open quarries, and now the mines are carried on under ground, like copper or coal mines. The ores here are chiefly silicates and blende, the latter being a sulphide. When they are first brought to the surface they are carefully sorted, the silicates and sulphides being kept separate. After all the large pieces have been picked out by hand, the mud and small pieces are washed in the same manner as copper ore. By this means nearly all of the mud and lime is removed, and nothing is left but good ore. It is then thrown on wagons and hauled across the South Mountain to the works.

The richer ores are used for making spelter, while the poorer are sent to the oxide works. The company keep a chemist in their employ, whose business it is to determine the value of the ores and slugs. The sulphides are first roasted to drive off the sulphur and convert the zinc into an oxide, and the silicates are calcined to drive off the water. The subsequent treatment of the ores is the same. They are ground in a mill with a certain proportion of stone coal, which mixes them thoroughly with the coal, and at the same time reduces them to a coarse powder. If they are intended for making oxide, they are taken at once to the furnace house. This consists of a long range of furnaces resembling those of a brick kiln. Into these the mixed ore and fuel is fed; the ash pit is then banked up tight with ore, and the fire door is also almost closed. The operation then goes on for eight hours without much attention from the workmen. The zinc, being intensely heated in contact with the fuel is reduced to the metallic state. As the metal is volatile, it at once rises in the form of vapor; but a stream of air being allowed to flow over the surface of the burning mass, the zinc at once takes fire in this and is converted into oxide. This is carried forward mechanically by the strong current of air that is continually drawn through the furnace by a powerful fan. By this means it is drawn through a falling sheet of water, which removes any unburnt particles of zinc or carbon, and the oxide issues from the tower perfectly pure, but still of a yellow color. It then passes through the fan and is blown into a large settling chamber, where the coarser particles of the oxide are deposited, and whence they are removed from time to time and returned to the furnaces to be worked over again. The finer particles by this time having become cold and snow-white pass on into the bag room. This is a large room hung with rows of long cotton bags, reaching from ceiling to floor and doubled up at the lower end, which lies for a yard or more on the floor. This room presents a singular sight when the fan is running and all the bags are fully inflated. These bags serve to filter the oxide from the air with which it is mixed. This, however, they only partly do, for the oxide, when shaken from them and collected in other short bags, is still a very light, bulky powder, full of air. In order to render it more dense it is passed beneath a roller several times on a table so arranged that it rises toward the roller at each passage. The bag which goes into the machine fat and portly comes out shorn of its fair dimensions.

The oxide is then packed in barrels lined with paper, and is ready for market. It is very extensively used for inside paint work, and in situations which are exposed to sulphuretted hydrogen is far superior to lead, as it maintains its white color where lead is quickly defaced. It is not, however, equal to the lead paint in brilliancy or in covering power.

The portion of zinc ore destined to be converted into spelter, which contains, we believe, all the roasted sulphide as well as the richer portions of the silicates, is then taken to the spelter furnace. This consists of four separate furnaces built into one block, the two pairs facing opposite ways, with two furnace doors at each end. These furnaces each contain forty-eight clay retorts. These retorts are about seven inches in external diameter, and three feet long. They are made of very refractory clay, so that they can stand prolonged heating. The company manufactures its own retorts in another part of the works. The men will remove one retort from the furnace and insert another without cooling off the rest. These retorts are all closed at the end that rests upon the back wall of the furnace; the outer end, which is placed lower than the inner, is open. The workmen fill these retorts with a semi cylindrical shovel, and then pass an iron rod into each so as to make an open passage at the top. They then place an earthenware adapter on the mouth of the retort, cementing it with clay. This is of a conical form, about a foot or so in length, and serves as a condenser, and being inclined upwards while the retort is inclined in the opposite direction, it forms a sort of cup or basin at its union with the body of the retort. In this basin the melted zinc collects. To the end of this adapter is fixed a *prolonge* of sheet-iron which serves to catch any zinc that may have escaped the adapter. In this prolonge are often found most beautiful crystals of zinc resembling moss in their delicacy. The furnace being charged, the work of reduction soon commences. The zinc, oxide, and coal react on each other, and the zinc is reduced to the metallic state while the coal escapes as carbonic acid and carbonic oxide. The metallic zinc, being volatile, is sublimed and carried along with the current of carbonic oxide, and is deposited mostly in the adapters, which become hot enough to keep it melted. Some little, however, escapes to the prolonges, and a little is carried still further and burns along with the carbonic oxide at the end of the prolonge. These burning vapors and the red glare of the furnace give the place a rather uncanny look after dark.

The furnaces are kept going day and night until they wear out. The melted zinc is withdrawn from time to time by a small scraper (the prolonges having first been removed) into large iron ladles, from which it is poured into the ingot moulds. These are of iron, and have the name of the company cast upon them in raised letters so that every ingot is marked. If it is intended for the market it is now ready, and we may say in passing that the spelter manufactured here is superior to any foreign product in the market, being free from all impurities except a trace of iron and carbon. Arsenic is never found in it, while that of foreign makes is rarely free from this impurity. If the spelter is to be rolled into sheets, it is taken to the rolling mill and placed in a reverberatory furnace, where it is again melted; from here it is dipped out in iron ladles and cast in broad, flat ingots; these are not marked, but are perfectly smooth. These ingots are heated up to the proper temperature to make them tough (which is from 212° to 280° F.), and then passed through rollers, one at a time at first, then two or three together, and finally a number of them at once, the workmen taking care to keep them at the proper temperature by returning them to the annealing furnace as often as they get cool. They also in the process of rolling continually shift them so as to bring fresh sheets next the rollers. When the sheets are finished they are trimmed at the edges and then weighed and marked, and packed in barrels for shipment. Many of the workmen employed here are Belgians, who were brought to this country by the company. There are also some Irish and a few Germans among the workmen. As a result of this the local dialect of South Bethlehem is an exceedingly curious one. We have often been amazed at hearing a boy, evidently of Irish extraction, talking a mixture of English, French, and German.

LUNAR LANDSCAPES.

Our readers do not need to be told that the moon is our nearest neighbor among the heavenly bodies, but possibly they may have a somewhat vague idea of *how much* nearer she actually is than any other of these celestial "outsiders." All the planetary distances are on so vast a scale compared with those to which we are accustomed on the earth, that we have no clear conception of them. We know that some are much greater than others, but the least and the largest really seem quite alike to us. It is only when we manage to bring them into direct comparison with our every-day measures that we can approximate to an appreciation of either their absolute or their relative magnitude. Before we make our imaginary visit to the moon, let us try by some such comparison to estimate the extent of the journey that lies before us.

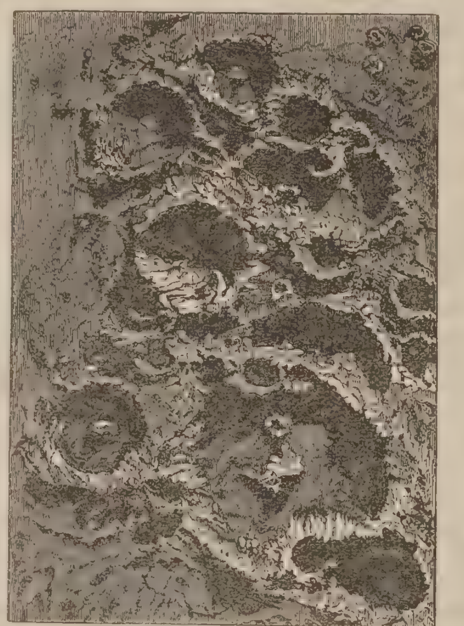
The mean distance of the moon, — no mean distance in itself, though insignificant when compared with the planetary intervals, — is about 240,000 miles. This is some nine times the circuit of the earth, or eighty times the distance from Boston to Liverpool, or across the Continent to California. A railway train, running day and night at the rate of thirty miles an hour, would get there in about *eleven months.* That would be a sufficiently tedious trip, but if we were going to the *next station,* in other words, to the planet Venus, which is about *twenty-five millions* of miles distant when nearest the earth, it would be more than a hundred-fold further, and some *ninety years* would elapse before we arrived at "the star of love." If we were bound for the sun (about sixty-seven million miles further in the same direction) it would take nearly two and a half centuries more to accomplish the distance.

It is evident that railway travelling is too slow for even the shortest of these little extra-terrestrial excursions. Let us take "the wings of the morning," and fly with the speed of the dawning sunbeams over the spaces that separate us from other worlds. A ray of *light* will reach the moon in a little more than a single *second;* while it will take more than *two minutes* to flash across the interval that divides us from Venus, and about *eight minutes* to travel back from the earth to the solar orb whence it emanated. A comparison of these periods of time will serve to show how much nearer to us the moon is than either Venus or the sun.

Of course, our satellite is proportionally near as seen through the telescope. Viewed with the highest magnifying powers, her surface is virtually not farther from our eyes than the outer portions of the terrestrial landscape visible from the summit of a lofty mountain. Objects three or four hundred feet in length can be distinguished, and if the "lunarians," or lunatics (or whatever the men in the moon are to be called), should erect buildings as large as some of ours, we could doubtless recognize them. Thus far, nothing of the kind has been detected, nor have we indisputable evidence of any change whatever in the lunar topography. Such changes have often been suspected, but more careful observations have failed to confirm them. Many keen eyes are now systematically watching the lunar surface, in hope to detect minute changes in its configuration, and we may expect that if volcanic or other forces are even moderately active there, the fact will soon be established beyond a doubt.

But what are the main features of the lunar topography? With the naked eye we see that the surface of the moon is diversified with light and dark regions, which at once suggest the idea of continents and seas like those on our own globe. And the early astronomers believed that the darker portions were seas, and they are called *maria* (Latin for *seas*) on lunar maps to this day, though it is doubtful whether there is any water at all on the moon.

An examination with more powerful telescopes has shown that these so-called *seas,* like every other portion of the lunar surface, are more or less uneven and rocky. There can be no doubt that they are simply vast plains, rough and rugged in many parts, but lying at a lower average level than the more luminous or mountainous regions. The moon is really far rougher and wilder in its mountain scenery than the earth. The loftiest lunar mountains are 23,800 feet high, or nearly as high as the Himalayas, while the diameter of the moon, (about 2,160 miles) is little more than one fourth that of the earth. They are, therefore, relatively as lofty as mountains sixteen or eighteen miles high would be on our planet.



On every part of the lunar surface, so far as we see it (it must be borne in mind that we see but one side of the orb), we perceive *ring-like* mountains, some very small, others from fifty to a hundred miles in diameter. These are doubtless of volcanic origin, though the largest far exceed the dimensions of any terrestrial craters. One of our illustrations shows a group of these craters or ring-mountains; the other is a view of *Copernicus,* one of the most remarkable of these annular formations. This huge crater is about fifty-five miles in diameter, and the greatest elevation of the mountain wall is 11,250 feet (more than two miles) above the surrounding plains. The wild and jagged outlines of the western wall are reproduced in the black shadow thrown on the interior level. The opposite peaks are seen in the full glare of the sunlight, broken only by the dark clefts and ravines into which its rays do not penetrate. It is these shadows that enable us to measure the heights of the mountains, and this can be done with great accuracy.

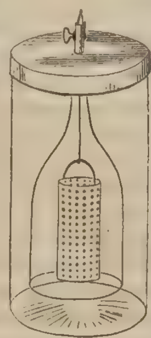
We have said that there is probably no water in the moon; and it is also certain that there is no atmosphere, unless it be one with very little depth or density. *Twilight* is the result of the refraction and reflection of light in its passage through the air, and there is no perceptible twilight on the moon. The same absence of refraction is noticed when a star is *occulted* by the

moon; that is, when the star is hidden by the moon's passing in front of it. If there is a lunar atmosphere, it cannot be a thousandth part as dense as ours; in other words, it is of greater tenuity than the best *vacuum* we can obtain by an ordinary air-pump.

Over the dreary and desolate landscape of the moon, therefore, no twilight ever softens the transition from day to night. The setting sun blazes with noontide splendor until it sinks below the horizon, and the blackness of midnight instantly supervenes; and no auroral crimson in the East gives prophecy of his rising, when, after a night that has lasted through fourteen of our days and nights, he bursts forth with dazzling brilliancy to begin a day of equal length. No clouds ever veil his steady glare, or add the varied beauty of their forms and colors to the unchanging sky. No breeze ever blows across those barren plains, or through those wild valleys. No rain, or dew, or snow ever falls there; nor can there be any other of the phenomena, either in the heavens above or on the moon beneath, that depend on the presence of water or of air. No sound is possible, — at least, none that is transmitted by atmospheric vibrations; but silence as of death reigns far and wide over a world destitute of all vegetable and animal life. If any form of life *does* exist there, it must be wholly unlike any with which we are acquainted, or of which we can conceive. We will not set limits to Divine power, nor deny that beings may have been created capable of living and enjoying life in such a sphere as the moon appears to be; but it would be no less presumptuous, on the other hand, to assume the existence of such beings before we have any evidence of the fact, direct or indirect. So far as the present condition of the moon is known to us, it seems to be, as some one has aptly called it, "a world in ruins."

A SIMPLE HYDROGEN GENERATOR.

The ordinary form of hydrogen generator, lustrated in the accompanying figure, is doubt-ss familiar to most of our readers that are iterested in chemical experiments. It consists f a glass vessel with a metallic over, through which, by an air-ght joint, a tube passes into the lass bell within. The latter is pen at the bottom, and a perfo-ated copper bucket is hung inside. he bucket is filled with granu-ated zinc or zinc cuttings; and ie outer vessel with sulphuric cid diluted with about ten parts f water. When the stopcock is pened, the air is driven out from ie bell, and the dilute acid com-



ig in contact with the zinc causes a brisk evolu-ion of hydrogen. If we close the stopcock, the ccumulation of the gas forces the liquid out of the ell, and the chemical action ceases until the cock ; opened again and the hydrogen allowed to es-ape. The *automatic* character of the apparatus nakes it extremely convenient, but it costs more han some amateur experimenters may be able to fford. If so, they can make a cheap and sim-le substitute by using instead of the outer vessel large wide-mouthed bottle, closed with a cork, nd for the bell a smaller bottle, with one or more oles drilled through the bottom of it, into which ie zinc is put without any bucket. Let the neck f the smaller bottle pass through the cork of the arger one, and close the smaller one with a cork tted with a stopcock or something that will nswer the same purpose. A glass tube with a mall cork will do, but the stopcock is worth the lditional cost. The cork or cover of the larger ottle must *not* be air-tight, but that of the naller one must be absolutely so; and of course are must be taken to drive out all the air before sing the hydrogen, especially in *burning* it, as ie mixture of hydrogen and atmospheric air is ighly explosive.

WINE-MAKING IN BURGUNDY.

An interesting work on "The Origin, Nature, id Varieties of Wine," by Drs. Thudichum id Dupré, has recently appeared in London. he description of some of the processes of ianufacture must be peculiarly appetizing to ie lovers of certain "brands" of wine. An nglish reviewer quotes the following from the iapter upon Burgundy, and we remember read-ig a humorous account of the same operation Flagg's "European Vineyards" (published a ear or two ago by the Harpers), in which it is iggested that it is intended to "give a *body* to ie wine:" —

"Now comes a phase in the production of Bur-indy, which is unparalleled by any proceeding in iy wine-producing country. The fermentation is implete, and the wine has to be drawn; but it is esired to impart to the wine all the color that can e extracted from the husks. For this purpose the usks which are collected in the *chapeau* [crust] ave to be thoroughly mixed with the alcoholic uid. The top of the *chapeau*, which is mostly a ttle rotten and sour, is therefore taken off, and vo or three men, having laid aside their clothes, ount to the top of the *chapeau*. The *chapeau* is dense that the men can stand upon it for some me. Each of the men works a hole with one foot rough the crust; he then gets his other foot through, and gradually succeeds with much trouble in causing his body to sink down through the crust into the wine below. While thus engaged, the whole *chapeau* is broken to pieces and worked together with the wine. These men now work the whole of the murk, and mix it thoroughly in all directions with the wine for about half an hour. They then emerge from the liquid covered with a dark red dye, and after wiping their bodies with the shirt they pulled off, they put on a fresh shirt and re-dress. After the lapse of several hours, the *chapeau* has again risen as before. The men then again descend into the fluid, and mix it with the *chapeau* as before. During this operation the men perspire profusely, not only from the intense labor which they perform, but also from the poisonous effect of the carbonic acid gas exhaled by the fermenting mass. They are mostly deadly pale or blue, and pant and hang their heads over the edges of the *cuves*, gasping for fresh air."

THE VELOCITY OF VISION.

We say "quick as sight," and the popular notion doubtless is that the phrase is synonymous with *instantaneous*. It is certain, however, that it does take time for the impression made upon the eye by a visible object to pass to the brain by the telegraphic line of the optic nerve and thus to reach the mind; but the time is so brief that we might suppose it impossible to measure it. But scientific men, after tracking the speed of light and electricity, were not to be baffled by a problem like this. Some time ago, Helmholtz and Exner demonstrated, by a series of experiments, that if a number of letters printed on white paper be presented to the eye, sometimes one, sometimes two or more of them, are distinguished from the rest, according to the duration of the impression and that of the image formed by it. More recently M. Baxt, of St. Petersburg, has been experimenting with an apparatus similar to that employed by Helmholtz, consisting of two discs, which could be made to rotate at known speed, the posterior one with twelve times the velocity of the anterior. The results at which he has arrived are summed up in a paper communicated to Pflüger's *Archiv für Physiologie*, of which the *Academy* gives the following abstract: —

"From the numerous experiments given, it appears: 1. That the consciousness of a given excitation is only realized or perfected by degrees; and 2. That, under the particular circumstances of his experiments, a period of one twentieth of a second must elapse between the occurrence of a relatively simple excitation of six or seven letters suddenly placed before and withdrawn from the eyes, and its reception or formation in the consciousness. In other experiments he found that the time required for the comprehension of a complex figure was much greater than that for a simple figure, the proportion between an ellipse and a pentagon, for instance, being as 1 to 5. Researches on the time requisite for the production of consciousness with various strengths of illumination gave the result that this time was proportionate, within rather wide limits, to the degree of illumination; but if illumination was excessively strong or weak, it increased."

HYGIENIC AND CULINARY HINTS.

Lemon Syrup. — When lemons are abundant and cheap, as they are now, it is a good plan to purchase several dozen at once, and prepare them for use in the warm, weak days of spring and summer, when acids, especially citric and malic, or the acids of lemons and ripe fruits, are so grateful and so useful.

Press your hand on the lemon and roll it back and forth briskly on the table to make it squeeze more easily, then press the juice into a bowl or tumbler, never into tin; strain out all the seeds, as they give a bad taste. Remove all the pulp from the peels and boil in water, a pint for a dozen pulps, to extract the acid. A few minutes' boiling is enough, then strain the water with the juice of the lemons, put a pound of white sugar to a pint of the juice; boil ten minutes, bottle it, and your lemonade is ready. Put a tablespoonful or two of this lemon syrup in a glass of water, and you have a cooling, healthful drink.

Lemon Butter. — One pound of white sugar, one quarter pound fresh butter, six eggs, juice and grated rind of three lemons, taking out all the seeds. Boil all together a few minutes, till thick as honey, stirring constantly; put in small jars, or tumblers, covered with paper dipped in white of egg. One teaspoonful is enough for a tart or cheese-cake. This will keep a long time in a cool, dry place.

How to Mix Mustard. — Mustard should be mixed with water that has been boiled and allowed to cool; hot water destroys its essential properties, and raw cold water might cause it to ferment. Put the mustard in a cup, with a small pinch of salt, and mix with it very gradually sufficient boiled water to make it drop from the spoon without being watery. Stir and mix well, and rub the lumps well down with the back of a spoon, as mustard properly mixed should be perfectly free from these. The mustard-pot should not be more than half full, or rather less, if it will not be used for a day or two, as the mustard is so much better when fresh made.

Cooking Raisins. — It is well to cook raisins before putting them into pies, cakes, or puddings. Soaking them is not sufficient. Steaming them by pouring a small quantity of boiling water amongst them in a tightly closing dish, and allowing them plenty of time to cook before opening, is a good plan. When raisins are rightly cooked before using, they are plumper, and more palatable, and can be eaten without injury by most dyspeptics.

Chicken Cheese. — Boil two chickens till tender, take out all the bones and chop the meat fine, season to your taste with salt, pepper, and butter, pour in enough of the liquor they were boiled in to make it moist, put into whatever mould you wish, and when cold turn out and cut into slices.

HOUSEHOLD RECIPES.

A Good Cement. — The following has been tested for cementing wood, iron, leather, glass, paper, and almost all kinds of household materials: Best isinglass, half an ounce; rub it between the hands until it breaks down into a powder, put in a bottle, and put as much common acetic acid to it as will just wet the mass through, stand the bottle in some boiling water, and the paste will dissolve and be fit to use at once; it will be solid when cold, but is easily warmed up the same as before. Leave the cork out when warming, or there is danger of bursting the bottle.

Zinc White for Polishing Silver, Britannia, etc. — Those who have tested it say that the very best article for cleaning silver, and other metallic ware is the zinc white (No. 1 quality) used by painters. Rub it fine with a knife, sprinkle it on a soft flannel cloth, with which rub the ware; then brush off with tissue paper or any clean soft cloth.

To Preserve Pegged Boots and Shoes. — If pegged boots are occasionally dressed with petroleum between the soles and upper leather, they will not rip. If the soles of boots and shoes are dressed with petroleum they will resist wet and wear well. The pegs, it is said, are not affected by dryness after being well saturated with the liquid.

The Arts.

FIRE-PROOF FLOORS.

A valuable paper on this subject was lately read by Professor Lewis, before the General Conference of Architects in London, an abstract of which we believe will interest many of our readers.

In dwelling-houses, the floor timbers usually bear at each end on a wall or partition; and even if the latter is of wood, it can be made almost fire-proof by filling in between the timbers either with plaster or with brick and plaster. The filling, however, must be carried up the whole extent of the partition, without vacancies between the floors.

The wall-plate should not be supported by stone or iron corbels, for these are liable to be shivered under the action of fire. A safe bearing may be obtained by forming "oversailing" courses of brickwork, which are proof against the fiercest fire.

In a dwelling-house, wrought iron joists, filled in with plaster "pugging," are a good protection, provided the under side of the joists is well protected by plaster; but *wooden* joists answer as well, filled in with a thick layer of pugging, if the latter is combined with the plastering of the ceiling, so as to form the two into one mass. The constructional difficulties in this case are greater than with iron joists, but by no means insurmountable. It may be noted incidentally that the slight joists used nowadays are a poor defense against fire, compared with the heavy timbers that we see in old houses. On this point Professor Lewis says: —

"As architect to one of the chief insurance offices, and also to the London Fire Brigade, I have seen several thousand cases of fire, and it has been very rare indeed in the case of a dwelling-house, that a solid piece of lumber has been burnt in more than an inch or so. A girder would be safe; but such an injury to one of our light joists would be fatal."

But the real difficulties of fire-proof construction begin where there is a great mass of combustible matter, as in warehouses. In a conflagration these become glowing furnaces, hot enough to melt brass and iron. Here the usual dependence is on iron; but the iron may melt, and long before it is heated to that point it will soften and lose its strength; and even before it begins to soften it may be snapped asunder when suddenly cooled by water thrown upon it. This last risk is the most serious, and it is mainly owing to the "exposure of the iron to the direct action of the flames," a radical defect in nearly all the so-called "fire-proof flooring."

There is another objection to iron girders. They are expanded by the heat, and strain the walls; while the burning of wooden ones would leave the walls intact. In fact, it is safer to use thick wooden girders and brick arches, than to depend upon iron. In the case of a large warehouse in London, all the iron girders snapped in two under the action of fire, while wooden girders in the same building were burned an inch deep, but were otherwise uninjured.

The writer speaks of the plan of having the iron girders and columns hollow, and keeping them filled with water, as a "favorite" one in England; but, aside from the danger of leakage, a fire will soon convert the water into steam and blow it off, if the hollow work is open to the air; while if it is closed, "the whole of the iron work will soon assume the conditions of a steam-boiler with its safety valves screwed down."

The conclusion to which Professor Lewis comes (and which, by the way, we know to be indorsed by good architects in this country) we will give in his own words: —

"In fact, the result really seems to me to be that the only secure protection from fire is a structure of brick arches on brick supports. Nothing else that I can call to mind will stand the effects of great heat and the action of flames; stone and granite fly to pieces, but good brick-work never does. Perhaps the strongest case of endurance against fire known of late years was that at Tooley Street, where an immense range of cellars were filled with oil, which ignited. For weeks this oil was burning, a rolling sea of fire. The cellars were vaulted with brick. They had this glowing mass below, and the heated *debris* above; and yet, after a careful scrutiny, when the oil was got out, I could detect scarcely a trace of injury. If this mode of construction cannot be used, I would trust strong wooden timbers thickly pugged and supported on strong wooden posts, in preference to iron girders on iron columns. But I cannot repeat too strongly, that, with a large mass of fire, no construction under any circumstances could be really fire-proof, except solid arches on brick supports."

MEMORANDA IN THE ARTS.

Danger in the Use of Copper Gas-Pipes. — The French *Journal de l'Éclairage* states that a workman, who with a triangular file had cut almost half through a gas-pipe of copper, $\frac{3}{8}$ inch interior diameter, which supplied the Liège station, was removing the tool, when an explosion took place, with a noise like the report of a rifle, and the man was much burnt. A similar explosion, but less violent, happened subsequently, and the workman, who was not injured, did not report the circumstance. Some gas-pipes having been taken down, they were found covered with a blackish coating, and they showed evident signs of corrosion from ammoniacal condensation. The black matter was analyzed, and was found to consist of acetylide of copper, which explodes between 203° and 248°.

Moving a Chimney. — The Cabot Company, of Brunswick, Maine, in order to enlarge their cotton mill, moved their large smoke-stack chimney — 78 feet high, 7 feet 9 inches square at base, and 5 feet square at top, containing more than 40,000 bricks, and weighing more than 100 tons — twenty feet, without rollers or balls or guys or braces to steady it — one of the greatest feats ever performed in the State. It was planned and carried out by the Company's Superintendent, not one of those engaged having ever witnessed the moving of such a body. It was accomplished by building such ways as are used in launching ships, surfaces planed, greased, chimney wedged up, and moved by two jack-screws in four and a half hours. The flues were disconnected from the boiler at 1 o'clock p. m., and $9\frac{1}{2}$ o'clock the same evening the flues were again connected, fires going, and steam up.

Weights of Wrought Iron and Steel. — Rules: *For Round Iron.* — Multiply the square of the diameter in inches by the length in feet, and by 2.63, and the product will be the weight in pounds avoirdupois, *nearly. For Square Iron.* — Multiply the area of the end of the bar in inches by the length in feet, and by 3.36; the product will be the weight in pounds avoirdupois, *nearly. For Square, Angled, T, Convex, or any Figure of Beam Iron.* — Ascertain the area of the end of each figure of bar in inches, then multiply the area by the length in feet, and that product by 10, and divide by 3; the result will be the weight in pounds avoirdupois *nearly. For Square Cast-Steel.* — Multiply the area of the end of the bar in inches by the length in feet, and that product by 3.4; the product will be the weight in pounds avoirdupois, *nearly. For Round Cast-Steel.* — Multiply the square of the diameter in inches by the length in feet, and that product by 2.67; the product will give the weight in pounds avoirdupois, *nearly*.

New Method of Nickel Plating. — A simple and cheap method of nickel plating, which, not being patented, is open to the use of all, has been invented by Prof. F. Stolba. The process is, in brief, as follows: Into a vessel of porcelain or metal, preferably copper, is poured a concentrated solution of chloride of zinc, made by dissolving commercial zinc in common hydrochloric acid. From once to twice the volume of water is added, the solution heated to boiling, and hydrochloric acid added drop by drop until the precipitate (formed on diluting the chloride of zinc with water) is redissolved. As much zinc powder as will cover the point of a knife is now added, whereby the metal of the vessel becomes zinc plated. Enough nickel salt (the chloride or sulphate or the double sulphate of nickel and potassium) is introduced to color the liquid distinctly green, after which the articles to be plated, with surfaces perfectly free from fat and rust, and with them some small cuttings of zinc, are put in and the liquid again boiled. The work is finished in about 15 minutes. If any part of the articles is not plated, the boiling is continued, fresh pieces of zinc and, if necessary, fresh nickel salt being added. It is important, if the coating of nickel is to be brilliant, the liquid on boiling shall not be cloudy from basic zinc salt, or acid from free hydrochloric acid. The plated articles are well washed with water and cleaned with polishing chalk. The same liquid may be used repeatedly for plating. The nickel salt need not be chemically pure, but must contain no metals precipitated by zinc.

Phosphor-Bronze for Guns. — Experiments upon phosphorized bronze as a material for guns are now engaging the attention of many of the European Powers. For some time past important trials have been going on with guns of this material in Prussia, and, it is said, with the most satisfactory results. The Swiss Government have under trial a breech-loader of phosphorized bronze; the Dutch Government, a muzzle-loader; the Italian Government, having repeated the statical tests which were applied to this material by Messrs. Montefiori-Levi and Künzel, of Liège, have resolved upon proceeding to the trial of guns of the material; and in Vienna some phosphorized bronze guns are about to be tested. Finally, the French Government are about to make some guns with this bronze, supplied from Liège.

Railway through the Alps. — There is a prospect of a fourth railway being made through the Alps before long. The Brenner Pass was the first, the Cenis tunnel was the second, arrangements have been made for constructing the third by the St. Gothard, and now active negotiations are on foot for traversing the Splugen. It is stated that two contractors have offered to make the line for two millions sterling. The cantons of Grisons and St. Gall are willing to furnish one half of the amount. It is proposed to work the line by bogie engines, so as to take the trains round very sharp curves. In this way a tunnel of less than a mile would be sufficient. The St. Gothard line will have a tunnel of eight miles.

PRACTICAL RECIPES.

To Bronze Articles of Plaster of Paris. — To a solution of soda soap in linseed oil, cleared by straining, add a mixed solution of four parts blue vitriol and one part copperas, which precipitates a

mixed cupreous and ferruginous soap; wash with cold water, strain, and dry. The product has a peculiar bronze hue. The dry powders are thus applied. Boil three pounds of linseed-oil with twelve ounces of finely-powdered litharge, strained and allowed to clear by standing. Fifteen ounces of this, twelve of the metallic soap, and five of whole wax, are mixed together by the aid of a water-bath, and the melted product applied with a brush to the plaster cast, which is previously heated to about 200°.

Blue-Black Copying Ink. — Aleppo galls, bruised, $5\frac{1}{2}$ ounces; cloves, bruised, 2 drachms; sulphate of iron, $1\frac{1}{2}$ ounce; sulphate of indigo, $1\frac{1}{2}$ ounce; sulphuric acid, 35 drops; rain water, cold, 40 ounces. Macerate the galls and cloves in 20 ounces of the water for eight days, decant and add to the solid residue 20 ounces of water, macerating for four days; decant. Mix the whole of the liquor, and finally add, in the order named, the sulphate of iron, the sulphuric acid, and the indigo.

To Stain Wood Black. — A correspondent of the *English Mechanic* gives the following directions: Brush the wood over with hot limewash, to remove all grease. Then give it a good dressing two or three times with logwood and nut-galls in decoction, first having removed the lime with a hard brush, and levelled the grain of the wood; afterwards dress with some vinegar, in which some old nails have lain. When black enough, rub well with a piece of black cloth and linseed oil, and, either varnished or polished, it will look equal to ebony, and will stand all weathers for years.

To Draw a Curve. — A plan but little known among draughtsmen, and most efficient for drawing fair curves, is the following: Cut a strip of soft pewter similar to that used for covering bar counters, about one sixteenth of an inch thick, and from one eighteenth to three sixteenths of an inch wide, the length of the longest curve required. Dress it straight, and smooth the edges with a file. By drawing the strip through the closed fingers of the left hand, or over the thumb, a very regular curve may be obtained, which can be altered at will till it matches the line to be drawn or copied. For fine or quick curves a slighter strip should be used.

To Fix Pencil or Crayon Drawings. — This may be done cheaply, simply, and without injury to the drawings, by varnishing them on the back with an alcoholic solution of white gum-lac. This solution quickly penetrates the paper, and enters even into the marks of the crayon on the other side. The alcohol rapidly evaporates, so that in an instant all the light dust from the crayons and chalk, which resembles that on the wings of the butterfly, adheres so firmly to the paper, that the drawing may be rubbed and carried about without the least particle being effaced. The following are the accurate proportions of the solution: 10 grammes of common gum-lac are dissolved in 120 grammes of alcohol; the liquid is afterwards bleached with animal charcoal.

A New Power. — We find the following in an exchange: "A Philadelphia mechanic claims to have invented a hydro-pneumatic engine which by means of one pound of water will produce one thousand pounds of power. The agents employed are air and water, by a new method of application. If this power is one third of what is claimed for it, steam, turbines, etc., have seen their last days." We do not, however, consider that those who are interested in the manufacture of steam-engines, turbines, etc., need have any serious apprehensions that their occupation is gone. Half a dozen of these "new powers" are announced every year, but we never hear anything more of them. That improved substitutes for the old motors will yet be found is not improbable, but even Yankee ingenuity has failed as yet to discover and perfect them.

Agriculture.

CONFUSED FARMERS.

How few husbandmen have any clear or settled convictions regarding the best methods of conducting farm operations! Bring together a hundred men engaged in soil cultivation, and how many of them will perfectly agree upon any one point which comes under discussion? Scarce half a dozen. Let a farmer give his views regarding the best method of growing a cabbage, and he will be confronted with opposing views from a score of his associates, and no two of the disputants will coincide in opinion. There is positively more confusion and doubt among farmers regarding the best and most effective treatment of soils, than there is among medical men regarding the proper treatment of disease; a condition of things quite extraordinary and unnecessary, to say the least.

Whenever a new man (that is, a merchant or manufacturer, retiring to the country) commences with much enthusiasm to till his freshly acquired acres, he feels that he needs information, and forthwith orders a supply of agricultural journals, and hurries to attend farmers' meetings and cattle shows. It is indeed curious to watch the effects of the information he obtains through these channels. The first year he says but little, plants his corn in a meadow according to the advice of Mr. A, and the last journal he read, or he ploughs a field upon a dry hill and drops his seed there, according to the suggestions of Mr. B, or some newspaper writer; he buries his manure a foot or two deep, or spreads it upon the surface, according as he is influenced by the last authority consulted; he uses phosphates and manures lavishly, or he don't believe in anything but cow dung, at ten dollars a cord, because at the last Farmers' Club he attended, on a close vote there was one majority against all kinds of mineral fertilizers. And so he moves on, covered by a cloud of doubt. The first season goes by, and at harvest time he gathers in what crops are worth saving, and still he is silent. The next year he reverses all his operations, feeling certain that success must lie in exactly the opposite direction from whence came failure. The results are still unsatisfactory, and the third year he spends in experimenting according to whatever whim or caprice may govern him. The fourth year the farm is advertised for sale.

This is no exaggerated view to present of the evils and losses which result from the empirical views and statements which find currency through the press and in discussions at agricultural meetings. Unfortunately those that know the least write and talk the most, and it is difficult to suggest a remedy for the affliction. Farming is a pursuit which demands intelligence, common sense, and a capability of discriminating between cause and effect. It is a calling encumbered with much prejudice and many absurd notions handed down from past generations. We must aid in dispelling these evils, and in placing agriculture upon a higher plane; the intelligence and progress of the age demand it.

Now, we believe there are some settled points in agriculture, — some facts, some principles which should be considered as removed from the field of controversy; and if we ever expect to make progress we must endeavor to multiply these settled facts. At another time we will endeavor to point out some of the fixed principles which may be regarded as safe to follow in soil cultivation.

FURTHER REMARKS REGARDING KAINIT.

The observations regarding Kainit, made in the last number of the Journal, have attracted much attention, not only among farmers but among importers and dealers in the agent. It is asserted by some large importers in New York, that kainit cannot be laid down in this country at \$13 the ton, and consequently the proposition of Mr. Grange of Baltimore to supply at that price is not made in good faith. We are unacquainted with any of the parties who offer to furnish the Stassfurth potash salts in this country, but it is due to Mr. Grange to say that he is not a jobber in these articles, but an *importer*, and he only proposes to supply kainit by the *cargo* at the low rate which we have mentioned. If farmers unite and give orders for several hundred tons, to be distributed among themselves upon arrival, they can have it at a low price, according to Mr. Grange's proposals.

One thing is certain: the compound called kainit is not worth to any farmer \$45, \$35, or even \$30 a ton, and if dealers will not furnish it at rates less than that, we advise every soil cultivator to let it alone. We do not advise farmers to purchase in large quantities at present, as we have not sufficient confidence in its fertilizing capabilities to lead us to do that. It contains much common salt (nearly one half), and that we regard as positively pernicious when used upon most soils and for most crops. We have never seen the least benefit from the use of salt; on the contrary, by its employment we have rendered some small patches in our fields almost barren. The most careful observers and experimenters in England have reached similar conclusions, and salt is but little used there at present. The potash element is the most valuable, and indeed we may say the *only* costly ingredient in kainit, and the explanations made in our last number will afford a fair idea of its true value. We incline to regard the Stassfurth *muriate of potash*, at present prices, as the cheapest agent. It can be purchased at about \$60 the ton, and it will give on analysis 90 per cent. pure chloride of potassium. This is a valuable salt, not as valuable as the sulphate of potash, since hydrochloric acid is not so desirable an acid as the sulphuric for soil application, but the agent has a marked influence upon the potato and other crops requiring large amounts of potash. In the use of all new agents proposed as valuable fertilizers, it is best to employ them sparingly until by repeated experiments we are made fully acquainted with their true value. We have much yet to learn regarding the *best forms* in which to employ each of the four great essentials of plant growths. It is not every compound that holds potash, or nitrogen, or phosphoric acid, that promptly and economically nourishes our cereal grains and roots, but much depends upon the *nature* of the combination, and to this department of study we must give earnest attention if we hope to attain satisfactory results.

THE EFFECT OF THE FOOD OF COWS IN THEIR MILK.

The Editor's Scientific Record, in *Harper's Magazine* for July, has the following: "It has lately been announced, as the result of careful and long-continued investigations, that the nature of the food given to cows does not produce the slightest effect upon the character or richness of their milk; the only difference being a greater or less percentage of water. The experiment was tried of feeding the same animals successively with hay alone; then, successively, with hay mixed with starch, oil, rape-seed, clover, etc., thus giving a greatly varying proportion of nitrogenized food. The milk was very carefully analyzed, after each change of food, without showing the slightest variation in its chemical constitution. The conclusion was, therefore, arrived at that the variation or improvement in the quality of the milk is to be accomplished rather by a careful regard to the breed than to the food supplied to the animal.

These remarks, of course, do not apply to the peculiar taste imparted to milk in consequence of the character of the food of the animal; since it is well known that the milk of cows which have fed upon garlic very soon furnishes evidences of that fact to the taste."

Remarks. — We do not regard the above statement as correct. The experiments made upon our herd of cows prove that the *quality* of the milk is sensibly influenced by change of food and treatment. The *caseine* and *butter globules* can be largely increased in the milk of cows by modifications of diet. Some cows at the farm, purchased of owners who treated them badly, and fed them poorly, improved wonderfully under better treatment, not only in the quantity of the lacteal secretion, but in the *quality.*

By the "richness" of milk, we suppose is meant the nutrient principles found in the fluid, and it is upon this understanding of the term that we base our dissent from the statement.

SEEDS AND CUTTINGS.

A New Fact in Agricultural Chemistry. — It has long been known that the quantity of nitrogen contained in cereal crops frequently very far surpasses the amount contained in the manured earth from which they are grown; and the manner in which the additional nitrogen has been acquired is one of the many puzzles of agricultural chemistry. That it is derived from the air, there is no question, but in what manner? Has it been absorbed by the plants directly from the air, or has it been first withdrawn from the atmosphere by some of the constituents of the soil, with which it could form compounds which were capable of vegetable assimilation? According to *Les Mondes,* M. Deherian seems to have succeeded in demonstrating that *in the presence of organic matter oxygen combines directly with nitrogen,* forming a compound analogous to the ulmic or humic acid, produced by neutralizing an acid with the potassic solution of garden mould. Into a perfectly dry tube he introduced oxygen, nitrogen, ammonia and glucose, and on heating the mixture found that a black nitrogenous matter was formed, while at the same time a portion of the nitrogen disappeared from the atmosphere of the tube.

Rain to Order. — The new system of weather signals is likely to enable the farmer to know pretty certainly when rain is coming; and it is not impossible that he may yet be able to have rain when he wants it, whatever the weather predictions may say. In England, where experimental agriculture is carried to an extreme almost unknown with us, the invention of methods of irrigation has been very ingenious. At Stoke Park, a tract of twenty acres is irrigated by artificial rain, the system being quite successful. The water was applied every night last summer in showers, except when natural rain made it unnecessary. The apparatus consists of pipes laid in the ground, supplied from an elevated reservoir, into which water was pumped by machinery. The financial exhibit made by the results of the experiment is said to be a good one. The interest on the money invested in the necessary machinery, and the cost of operating it, aggregated \$95 per acre for the entire tract of twenty acres. Likewise the income per acre aggregated \$200, being made up of the proceeds of one crop of grass and grazing in the autumn of 1870, and two crops of hay in 1871. The net profit was thus \$105 per acre. On land of the same tract and same character, used for the same purpose, but where the irrigation was omitted, the net profit per acre was but \$45.

A New Use for Fresh Eggs. — The *Scientific Press* quotes the testimony of a gentleman in San Francisco with regard to the value of fresh eggs in affording nourishment to weak animals. He remarked that he had known a young colt which to all appearances was nearly dead, the breath of life being barely perceptible, to be quite instantly revived by giving it one or two fresh eggs. The same results, in several cases to which he was knowing, have followed the administering of eggs to weak calves, and also to feeble and chilled lambs. A remedy so simple, so easy at hand and so effectual in the cases mentioned — which often occur with calves and lambs — should be remembered by our readers.

Keeping Cream. — Next in importance to having the milk perfectly pure and sweet, and freed from all animal odors, comes the matter of keeping the cream after it is taken off the milk. In the first place, the less milk there is with the cream at the time it is set in the cream jar, the better. A great deal of carelessness is shown in this matter, for be it known that milk makes cheese, while the cream only makes butter, and the more milk there is in the cream at churning time, the more cheesy-flavored will be the butter, and therefore the more likely to spoil afterwards unless excessively salted. Really pure good butter requires very little salt, while butter as ordinarily made will soon spoil unless well salted, or kept covered in brine.

Secondly, the cream jar must be of the very best quality of stone-ware; thick glass would be still better; and it must have a cover that will exclude all dust and insects.

Thirdly, the cream jar should be kept in a place where no noxious odors or gases can be absorbed when the jar is open to add more cream, and also where the temperature can be kept cool and equable, say at about 60°; and, lastly, the cream is to be made into butter as soon as it just begins to sour, and when the jar is emptied it is to be thoroughly cleaned and scalded in boiling water before being again used.

Grafting Wax. — The following recipe is from a practical nurseryman of large experience; resin, six pounds; beeswax, one pound; tallow, one pound; melt, and work until cold. This is to be used warm, when working in the house. For out-door work, use one pint of linseed oil in place of the tallow in the above formula; or take one to two pounds less of resin, one half to one pound more of beeswax, and one and one half pints of linseed oil; to be melted, made in a mass, and applied by hand.

Fowls Poisoned with Lead. — An English clergyman lately sent the editor of *Land and Water* some ducks and chickens which he thought were suffering with lead palsy, and it appeared from a *post mortem* examination of one of the ducks, which died soon afterwards, that his suspicions were well grounded. It seems that in the vicinity of lead works, especially in Wales, poultry and other animals often suffer from drinking the water of streams polluted by the lead ore washings. Horses and cows sometimes become diseased in this way. Mr. F. Buckland, commenting on the subject, says: "On the South Tyne I lately heard of an old hen-wife who, when her chickens are poisoned by lead ore, simply takes a knife, opens their crops, turns out the poisonous material with her finger, sews up the crops again and lets the birds go; they don't seem to mind having their crops cut open. I also heard of a whole flock of geese being poisoned by drinking water from a lead mine. In this case the loss to the owner was not very great, for he simply picked up his dead geese, and, instead of driving them alive in a flock into the neighboring town, he carried them in a cart and sold them as dead birds — without of course, giving 'the cause of death.' I never heard that anybody was poisoned by eating those geese. . . . . In the case of lead ore poisoning of chickens, ducks, and other birds, I think the fatal effects are produced not so much by the lead — as the miners do not allow much of *that* to go as waste into the river — but by the mundic sulphate of barytes and sometimes arsenic, which is contained in the lead ore washings."

As we have formerly reminded farmers, the animals they keep are as liable to suffer from the use of impure and polluted water as they themselves are; and yet they are often extremely careless with regard to the water furnished to their cows and other stock. This is to be both inhuman and blind to one's own interest. It is as unthrifty as it is cruel.

Poultry-Keeping for Women. — We have urged the importance of gentleness in the treatment of cows, and it is quite as important in the care of other domestic animals. The *Poultry World* (an excellent journal, published monthly in Hartford, Conn., at one dollar a year) incidentally refers to this point in recommending poultry-keeping for women. It says: "There are many women, who, especially within the last half-dozen years, while the price of eggs has been so high, make money much faster by tending poultry than by sewing. It is an occupation especially suited to women, because it involves patience and constant attention to details rather than strength. Then, again, the hardest thing for many men to learn, in handling either poultry or bees, is gentleness. How many times we have seen boys, and men with no more sense than boys, jerk hens roughly from their nests, enter the poultry-house abruptly and frighten the occupants till they rush in a fluttering mass into the farthest corner, and keep the poultry community in constant agitation and distress. But all domestic animals appreciate the manners of women attendants when they are fortunate enough to be cared for by them. Now that there are women gardeners and florists who by commendable industry and business qualities have risen to eminence in those callings, and while one of the most successful, if not *the* most successful, bee-keepers in the whole country is a woman, we hope to see others give poultry more attention than it has hitherto received. Aside from profit, the keeping of fine poultry for fancy is an elegant pastime very popular with English ladies, and we see no reason why the fashion should not be adopted here."

MAXIMS FOR THE FARMER.

1. *Only good farming pays.* He who sows or plants, without reasonable assurance of good crops annually, had better earn wages of some capable neighbor than work for so poor a paymaster as he is certain to prove himself.

2. *The good farmer is proved by the steady appreciation of his crops.* Any one may reap an ample harvest from a fertile virgin soil; the good farmer

alone grows good crops at first, and better and better ever afterward.

3. *It is far easier to maintain the productive capacity of a farm than to restore it.* To exhaust its fecundity, and then attempt its restoration by buying costly commercial fertilizers, is wasteful and irrational.

4. *The good farmer sells mainly such products as are least exhaustive.* Necessity may constrain him, for the first year or two, to sell grain, or even hay; but he will soon send off his surplus mainly in the form of cotton, or wool, or meat, or butter and cheese, or something else that returns to the soil nearly all that is taken from it. A bank account daily drawn upon, while nothing is deposited to its credit, must soon respond, "No funds;" so with a farm similarly treated.

5. *Rotation is at least negative fertilization.* It may not positively enrich a farm; it will at least retard and postpone its impoverishment. He who grows wheat after wheat, corn after corn, for twenty years, will need to emigrate before the term is fulfilled. The same farm cannot support (nor endure) him longer than that. All our great wheat-growing sections of fifty years ago are wheat-growing no longer, while England grows large crops thereof on the very fields that fed the armies of Saxon Harold and William the Conquerer. Rotation has preserved these, as the lack of it ruined those.

FLORICULTURAL NOTES.

Tenacity of Life in Portulacaceous Plants. — Specimens of *Lewisia rediviva*, a portulacaceous plant, large-flowered and fleshy, growing in British Columbia, Oregon, and California, will grow, although they have been dried and in the herbarium for two or three years; and indeed the samples are often troublesome from sprouting whilst between the papers. One species, collected by Dr. Lyall of the British Navy, was "immersed in boiling water" to stop this growing propensity, before submitting to the drying process, and yet more than a year and a half afterwards it showed symptoms of vitality, and subsequently it produced its beautiful flowers in the Royal Gardens at Kew. That pest of our gardens, purslane, belongs to the same family, and is almost equally hard to kill.

Sleeping Flowers. — Almost all flowers sleep during the night. The marigold goes to bed with the sun, and with him rises weeping. Many plants are so sensitive that they close their leaves during the passage of a cloud. The dandelion opens at five or six in the morning, and shuts at nine in the evening. The goat's-beard wakes at three in the morning, and shuts at five or six in the evening. The English daisy shuts up its blossom in the evening, and opens its "day's eye" to meet the early beams of the morning sun. The crocus, tulip, and many others, close their blossoms at different hours towards the evening. The ivy-leafed lettuce opens at eight in the morning, and closes forever at four in the afternoon. The night-flowering cereus turns night into day. It begins to expand its magnificent sweet-scented blossoms in the twilight; it is full-blown at midnight, and closes never to open again with the dawn of day. In a clover-field not a leaf opens till after sunrise. Those plants which seem to be awake all night have been called "the bats and owls of the vegetable kingdom."

Change of Habits in a Plant. — We referred, some months ago, to a singular instance of a recent change of habit in the case of the *Kea* or mountain-parrot of New Zealand. The same observer, Mr. Thos. H. Potts, has noted in *Nature* a somewhat similar instance of the change of habit in a plant. The *Loranthus micranthus* is one of the most showy parasites belonging to the New Zealand flora, and is nearly allied to the English mistletoe. Originally parasitic on native trees belonging to the orders *Violarieæ* and *Rutaceæ*, it appears now to have nearly deserted these in favor of trees introduced since the colonization of the island by Europeans, especially the hawthorn, plum, peach, and laburnum. The latter tree was only introduced in 1859, and appears now to be one of its most favorite resorts, where it is abundantly visited by the European honey-bee, also of recent introduction.

Loudon, the Landscape Gardener. — Loudon was a man who possessed an extraordinary working power. The son of a farmer near Edinburgh, he was early inured to work. His skill in drawing plans and making sketches of scenery induced his father to train him for a landscape gardener. During his apprenticeship, he sat up two whole nights every week to study; yet he worked harder during the day than any fellow-laborer. During his studious hours he learned French, and, before he was eighteen, translated a life of Abelard for an Encyclopædia. He was so eager to make progress in life, that when only twenty, while working as a gardener in England, he wrote down in his Notebook: "I am now twenty years of age, and perhaps a third of my life has passed away, and yet what have I done to benefit my fellow man?" An unusual reflection for a youth of only twenty. From French he proceeded to learn German, and rapidly mastered that language. He now took a large farm for the purpose of introducing Scotch improvements in the art of agriculture, and soon succeeded in realizing a considerable income. The Continent being thrown open on the cessation of the war, he proceeded to travel for the purpose of observation, making sketches of the system of gardening in all countries, which he afterwards introduced in the historical part of his laborious "Encyclopædia of Gardening." He twice repeated his journeys abroad for a similar purpose, the results of which appeared in his Encyclopædias — perhaps among the most remarkable works of this kind, and distinguished for the immense mass of useful matters which they contain, all collected by dint of persevering industry such as has rarely been equalled.

A Correction. — In our "Atoms" last month we stated, on the authority of one of our Western exchanges, that the corn raised at the Iowa Agricultural College cost double its market value. The fact is, that in the very dry season of 1870, when the crops in many neighboring fields were a total failure, the cost of the corn raised by the college was more than the *present* market price, but much below the price at that time. The corn raised last year appears to have cost only about *half* its market value, and the yield to the acre was nearly double the average in the vicinity for the same variety of corn. This is much to the credit of the college, and results like this will be the best possible argument in favor of the establishment of such institutions. We are heartily glad to make this correction, for while we have felt obliged to criticise the management of some of the agricultural colleges, we know that others are doing excellent work, and among these none, in our opinion, stands higher than the Iowa College.

A Point in Botany. — A correspondent, referring to the article in our last number, on "Wild Plants for Hanging Baskets," copied from the *Horticulturist*, in which "the yellow-blossomed wild strawberry (*Fragaria vesca*)" is recommended, says: "I have never seen, never heard of a yellow-flowered strawberry before." Perhaps, as he suggests, the writer had in mind *Waldsteinia fragarioides* of Gray's Manual; but there *is* a "yellow-blossomed strawberry" (*Fragaria Indica*, growing in Pennsylvania and the South, according to Wood), and she may have meant that plant.

BOSTON, MAY 1, 1872.

POPULAR SUPERSTITIONS.

It is the work of true science to dispel absurd and superstitious notions from the human mind, and to replace distorted and foolish beliefs by those founded upon the ascertained laws of nature, and the positive facts resulting from intelligent research. This work of science has been in a great measure performed, and many of the old superstitions have been rooted up and fully discarded. Still, there are some that remain, and they exert a decided influence not only upon the uneducated and the vulgar, but upon those of the opposite class.

Superstitions in especial reference to thunder and lightning seem to have abounded in every country from a very early period. It is believed among the Mohammedans at this day that safety from the destructive effects of thunder and lightning is insured by the presence of children, whose innocence is supposed to appease the wrath of the Almighty against the guilty; and this supposed charm is commemorated in some old Spanish verses. The German writers contribute amply to the general fund of mystic lore in connection with this subject, and the works of fiction of both French and Italian authors abound in similar allusions.

Lord Byron observes, "The eagle, the sea-calf, the laurel, and the white vine, were amongst the most approved preservatives against lightning in ancient times; Jupiter chose the first, Augustus Cæsar the second, and Tiberius never failed to wear a wreath of the third when the sky threatened a thunder-storm. These superstitions," he remarks, "may be received without a sneer in a country where the magical properties of the hazel twig have not lost all their credit; and perhaps (he continues) the reader may not be much surprised to find that a commentator on Suetonius has taken upon himself gravely to dispute the virtues of the crown of Tiberius, by mentioning that, a few years before he wrote, a laurel was actually struck by lightning at Rome.

"The Curtian lake and the Ruminal fig-tree in the Forum, having been touched by lightning, were held sacred, and the memory of the accident was preserved by a *puteal*, or altar, resembling the mouth of a well, with a little chapel covering the cavity supposed to be made by the thunderbolt. Bodies scathed, and persons struck dead, were thought to be incorruptible; and a stroke not fatal conferred perpetual dignity upon the man so distinguished by Heaven.

"Those killed by lightning were wrapped in a white garment and buried where they fell. The superstition was not confined to the worshippers of Jupiter; the Lombards believed in the omens furnished by lightning, and a Christian priest confesses that by a diabolical skill in interpreting thunder, a seer foretold to Agilulf, Duke of Turin, an event which came to pass, and gave him a queen and a crown."

It seems indeed an amusing idea that any one should write seriously in condemnation of such superstitions as these, in the nineteenth century. However extraordinary it may appear, it is

nevertheless an indisputable fact, that absurdities similar to the foregoing are actually believed and confided in for safety in England, to this hour; and by persons too not, in the ordinary sense of the word, uneducated. The fears of superstition, as well as its consolations, are peculiarly within that class of feelings which are said to begin in the nursery and end only in the grave; and so congenial to weak understandings is the love of the marvellous, and so despotic the control of the horrors of the supernatural, that the age of manhood is not always or necessarily the harbinger of the age of reason.

There are a great many popular superstitions in reference to other subjects, equally irrational with those on the subject of lightning, and which are very commonly resorted to by the ignorant. Among others, that in cases of persons drowned, if quills filled with quicksilver be stuck in loaves of bread, and thrown into the water, they will by some magic influence float about till they come directly over the spot where the dead body lies, and there remain stationary; little less ridiculous than the Irish legend, that the dead body, touched by the hand of its murderer, will indicate symptoms of reanimation. It is commonly believed among English farmers that bacon from pigs killed when the moon is on the wane will not be good; and in some places an idea prevails that in the construction of feather-beds the exclusion of certain feathers is indispensable for making an easy death-bed.

The highest and most educated, even the most eminent judges and divines, have been tainted with similar infirmities. It is yet barely a century since the penal statutes against witchcraft were repealed in England; and the superstitious trial by wager of battle was demandable so late as 1819. But the light of the present day is fast dispelling such foolish beliefs in this and all other countries, and soon they will cease to be remembered.

PROFESSORS TREADWELL AND MORSE.

WITHIN a short time America has lost two great inventors of whom she may well be proud. Professors Treadwell and Morse were both born in the year 1791, and have died within a month of each other. Prof. Morse's name is known throughout the world. Wherever the click of the telegraph is heard, there also has been heard the announcement that its inventor is dead.

And yet this invention was not perfected until its author was beyond the age at which many men think of giving up active business. The first successful line was the one from Baltimore to Washington, and was built in 1843. The man who made this invention possible, Prof. Henry, of the Smithsonian Institution, still lives. His discovery of induced magnetism supplied the one thing that was lacking in order to make the telegraph a success, for Franklin had discovered that electricity could be made to traverse wires. To Morse is due the credit of combining these discoveries, and inventing the machine to record the impulses of electricity sent through the wire.

Prof. Treadwell is less widely known than Prof. Morse, but he started on his career as an inventor at a much earlier period, having invented a machine for cutting wood screws when he was but little over twenty. He then turned his attention to printing-presses, and made and put in operation the first power-press that was ever used in America. He also invented the turn-out used on single track railroads, and machines for making heavy cordage, some of which are still in use. But the great invention of his life was the substitution of steel and wrought iron for cast iron or brass in the manufacture of cannon. His first device was the mere substitution of these metals, but he found that with the old form of gun this would be too expensive. He therefore made a careful investigation of the proper proportions of the various parts of the gun, and the result of his work was the adoption of the form of gun that is now used in the army and navy, in which every part is proportioned to the strain upon it. The working out of his ideas has produced those destructive engines of modern warfare known as the Armstrong, Krupp, and Blake guns, and all the vast array of steel and wrought iron ordnance.

By his will his property, after some small bequests are paid, is divided into five equal parts, of which one is given to each of the following institutions: American Academy of Arts and Sciences, the Boston Athenæum, the Boston Public Library, the Library of Harvard University, and the Public Library of the town of Ipswich, his native place.

SODA AND MINERAL WATERS.

THE approach of the warm season leads us to devote a few words to the consideration of the nature and healthfulness of the various beverages which are sold by druggists, confectioners, grocers, etc., under the names of soda water, mineral water, Seltzer water, etc. Within a few years the sale of these beverages has largely increased in most of the towns and cities in this country, and a vast expense is incurred by dealers in fitting up apparatus of marble and silver through which to dispense the effervescing liquids. The apparatus is certainly very elegant and attractive, and indicates that the business is so profitable as to be thought worthy of heavy outlays in order to provide counter appliances.

Soda water, or aërated water, is simply common water largely charged with carbonic acid under pressure. If this is prepared in a careful and cleanly way, and in proper vessels, there can be no serious objection to its being used freely during the summer months by persons in ordinary health; but if, on the contrary, it is manufactured by slovenly and incompetent dealers, and copper vessels are used, it becomes not only a filthy, but a poisonous beverage. Carbonic acid acts vigorously upon copper, forming the green carbonate of the metal, and when vessels are employed which are not coated with the metal tin, the poisonous salt is produced in large quantities. This is dissolved in the water, and when drank freely has a very pernicious influence upon the health. When copper fountains are opened by manufacturers for repairs, or for the purpose of re-tinning, they are often found covered with a deposit of copper salts, and we have seen crystals hanging from the upper surfaces like stalactites from the roof of a limestone cave. Too much care cannot be taken with copper vessels used for preparing aërated waters, and dealers owe it to their friends and customers not to allow them to be acted upon by the acid. The materials used in the manufacture of the water should be pure, and the utmost cleanliness and care observed in the manipulating processes. We wish that all copper vessels could be dispensed with, and we think that iron ones should be used in preference, as they have been employed successfully by many dealers.

Respectable and competent druggists are usually vigilant and careful regarding the character of the waters they dispense, and the beverage so cooling and grateful can be procured in a pure condition of those worthy of being trusted.

THE MINERAL PHOSPHATES.

SEVERAL correspondents have requested us to state the *exact* amount of commercial sulphuric acid required to decompose 100 lbs. of the South Carolina phosphatic rocks. It must be understood that these phosphates vary much in composition, but as they are generally sold by analysis it will be very easy to calculate in each case how much acid must be added to decompose the specimen. In the first place, we have to add enough to decompose the carbonate of lime, and convert it into the sulphate; then enough must be added to change the tricalcic phosphate into monocalcic phosphate, according to the following formulas: —

$$CaCO_3 + H_2SO_4 = CaSO_4 + CO_2 + H_2O$$
$$Ca_3P_2O_8 + 2H_2SO_4 = CaH_4P_2O_8 + 2CaSO_4.$$

Acid of 1.8426 sp. gr. has the formula H_2SO_4, so that we can calculate directly from the above equations how much to use.

For instance, the analysis gives the following composition of the phosphate: —

Carbonate of lime	5.00
Native phosphate of lime	60.00
Silica, Water, Organic Matter, etc.	35.00
	100.00

We have,

$$CaCO_3 : H_2SO_4 :: 5 : x$$
$$Ca_3P_2O_8 : 2H_2SO_4 :: 60 : y.$$

and $x + y =$ the amount of acid to be used. As the first two members of the above equations remain constant, we may simplify matters by dividing them once for all; and the rule then becomes, —

Multiply the per cent. of carbonate of lime and of phosphate of lime by the factors .98 for the carbonate and .603 for the phosphate.

$$\text{Then } 5 \times .98 = x = 4.90$$
$$60 \times .603 = y = 36.18$$
$$41.08$$

giving 41.08 pounds of acid for 100 pounds of the above phosphate.

The above will apply equally well to bone char, or any other phosphate of which the formula is known. It is best in practice, however, to use considerably less of the acid, in order to avoid the presence of any free sulphuric acid.

THE NAPHTHA FIEND.

UNDER the above head, the *New York Tribune* is doing a good work in exposing the dangerous frauds of the naphtha peddlers, and warning the people against their so-called "fluids," "oils," "gasolines," etc., which are warranted "inexplosive." W. H. Coleman, Esq., of Geneva, N. Y., sends the following communication to the *Tribune*, in which he alludes to the service the JOURNAL has performed in explaining the dangers of naphtha, and exposing the frauds in its sale. The "Danforth Fluid," alluded to in the communication, has been several times spoken of

in our columns, and its perilous nature pointed out.

To the Editor of the Tribune: —

Sir, — Your recent attack upon the naphtha peddlers of New York is well deserved and well performed. The credit for first exposing this devilish fraud is due to Dr. J. R. Nichols, of Boston, who, five years ago, in his *Journal of Chemistry*, fully explained the nature of kerosene and naphtha, described the methods used by dishonest dealers, and from time to time warned the public to be on their guard against every kind of burning fluid except pure kerosene. His efforts led to the passage of the first law ever enacted upon the subject, but the remarkable apathy of the public, who seemed ready to risk any danger for the sake of having a cheap and brilliant light, rendered it and similar ones nearly dead letters. Soon after my removal to this place, in 1870, a man called at my house to sell Danforth's Patent Non-explosive Fluid, which he highly recommended as being perfectly safe. I quickly saw that it was only a naphtha preparation, and told the man what I thought of it very plainly. On further inquiry, I learned that an agency had been established in the village, and that the sales were very large. I therefore wrote an article for the village paper, showing up the whole business, and denouncing the Danforth oil in plain terms. In a few days I was waited upon by both the local and the county agents, who questioned me closely as to my knowledge of oils, and said that Mr. Danforth would take the matter in hand. Next week the paper contained a reply from Mr. Danforth, denouncing the writer of the attack, offering a reward of $100 for the first case of explosion in the use of his oils, and daring me to meet him in a public test of his fluid and of kerosene.

Finding myself in for a fight, I placed a sample of the fluid in the hands of Professor Towler of the Medical College, for analysis, and with little effort hunted up several cases of well-authenticated explosions of the fluid. Prof. Towler's analysis proved all and more than I expected, for he not only exploded the fluid, but nearly set the college in flames. I then wrote to Danforth, naming day and place where I would meet him for the public test, giving him ample time to come on. He replied, saying that owing to press of business he could not come, but that the county agent would be in attendance. The day came, the local agent collected samples of all the kerosene in town, in the full belief that his superior would arrive to vindicate himself, and blow his opponents to parts unknown, and Prof. Towler and a few citizens awaited events at the college. The day passed, and nobody came. Then I wrote to Danforth, stating that I had exploded his fluid, and met all his requirements, and requested him to forward a check for that $100 which I had fairly earned. It is needless to say that it never came. However, all this did not seem to affect the local trade very greatly, though the agents were frequently changed. Finally, the store was closed, and the agency transferred to a man who kept an eating saloon on another street, and thereafter eatables and naphtha were sold together.

Last fall, returning from Rochester in the cars, I met the young man who was local agent at the time above spoken of. He had since gone into the tree-selling business, and talked very freely about his experience in the oil business. The county agent had cheated him out of his salary, and had himself been sold out by the sheriff. Danforth also, he said, had been arrested in Albany by a dupe to whom he had sold a local right, and who soon discovered that the right had been resold to dupe number two.

I supposed that this had finished him, until your exposé disclosed his agencies in New York. Finish him if you can, Mr. *Tribune*. He is a head centre in the naphtha trade, and must have made a handsome fortune — in fact, several of them.

Wm. H. Coleman.

Geneva, N. Y., *March* 9, 1872.

EDITORIAL NOTES.

Secretary Flint's Agricultural Report for 1871–2. — Some journalists outside of our State would have their readers believe that husbandry in Massachusetts is in a very bad way, and that our soils have become so exhausted as to be unfit for cultivation. The most excellent and interesting *Annual* which our Agricultural Secretary sends out from his office at the State House every year, is well calculated to dispel any erroneous impressions formed from reading careless statements in distant newspapers. We doubt if any volume is issued in any part of the country which contains so much that is of real value to the agricultural interests of the country as the Massachusetts State Report; and the volume just issued is one of the best of the series. It presents accurate reports of the discussions and addresses upon agricultural topics at the meetings of the State Board, and also many of the valuable papers which appear in the transactions of the local societies. It contains the results of the observations and experiments of some of the most careful and sagacious soil cultivators in the State, and a large amount of practical information is presented upon the raising of the cereal grains, fruits, roots, early vegetables, etc. The Secretary deserves much credit for his indefatigable efforts to promote the great interests of husbandry in this ancient Commonwealth.

Ohio "Schoolmarms" on Physiology, etc. — After a recent examination of female teachers in Ohio, some of the unsuccessful candidates complained that injustice had been done them, whereupon the examiners were so cruel as to publish extracts from the papers written by the rejected applicants. The following are a few specimens of the answers: "The food is first masticated, and then passes through the phalanx;" "Respiration is the sweating of the body;" "The chest is formed of two bones, the sternum and spinal cord;" "Emphasis is placing more distress on some words." One candidate says that "Virginia obtained its name from the Virgin Mary;" another that "it was so named by Queen Victoria calling it a Virgin State."

Force and Energy. — The distinction between these terms, now so often employed by scientific writers, is well stated in the following extract from an article by Dr. F. W. Pavy, in the *London Lancet*: —

"By 'force' in rigid signification is understood the power of producing 'energy;' by 'energy,' the power of performing work. To give an illustration: powder has force, the cannon-ball energy; but to speak of the force of the cannon-ball is inexact. I may also remark that the words 'actual' and 'potential' are in frequent use to qualify the state in which energy is met with. By actual energy is meant energy in an active state, energy which is doing work. By potential energy, energy at rest, — energy capable of doing work, but not doing it. In a bent cross-bow there is potential energy, — energy in a state of rest, but ready to become actual or to manifest itself, when the trigger is pulled. Again, actual energy is evolved from the sun. By vegetable life this is made potential in the organic compounds formed. In these organic compounds the energy is stored up in a latent condition; potential energy is reconverted into actual energy when they undergo oxidation during combustion, or in their utilization in the animal economy."

☞ For the cuts on page 122 we are indebted to Rolfe and Gillet's "Handbook of the Stars."

ATOMS.

Last year, 268,800 tons of iron were mined in Missouri, and 910,984 tons in Michigan. — We see that Professor Wedl contests Professor Lostorfer's boasted discovery of peculiar bodies in syphilitic blood, and asserts that they are only masses of fatty particles and protoplasm, which are found in healthy blood. — There were no less than 13,174 deaths from small-pox in the seventeen largest towns of Great Britain during the past year. — The manufacture of rails (for railroads) in this country has doubled in the last six years. — From some remarks in the *Pall Mall Gazette* on the necessity of a revision of the British marriage laws, we infer that in England no legal marriage can take place except in the "canonical hours," or between eight A. M. and noon. — We see that the paper on "Fire-proof Floors," to which we have elsewhere referred, is reprinted in full in *Van Nostrand's Engineering Magazine* for April. — The poet Whittier, in a letter to the editor of the *Literary World*, commends that paper as "filling, in a very satisfactory manner, an important but heretofore unoccupied place in our periodical literature," and says that he has "learned to place a high estimate upon the ability, candor, and conscientious thoroughness and impartiality of its critical reviews and notices." — Bouchardat has found milk sugar in the juice of the *Achras sapota* at Martinique; one sample containing fifty-five per cent. of cane sugar and forty-five per cent. of milk sugar. — It is popularly supposed that a wide-spread epidemic has a marked effect upon the general mortality, but statistics prove that the great tide which carries away the generations of men, is but slightly rippled in its flow by any such cause, and no "run" on the life insurance offices is likely to be the result. — According to Berthelot, benzoic chloride is a sensitive reagent for alcohol, being very slowly decomposed by water, while if the liquid contains .001 of alcohol, benzoic ether is at once formed, and may be recognized by its peculiar odor. — The Sewage Inquiry Commission, at Birmingham, England, report that the well water used by at least 105,000 of the population of that city "consists in reality of filtered sewage." — Dr. Letheby, in his "Lectures on Food," gives the following valuable piece of information concerning Indian corn, which will be as new to our Yankee readers as it doubtless was to the London cockneys: "The young grain, called cob, is, however, more palatable, and forms, when boiled in milk, an American luxury, which takes the place of green peas." — The celebrated cosmetic known as "Kalydor," is said to be made of bitter almonds, blanched, 1 ounce; corrosive sublimate, 8 grains; rose-water, 16 ounces. — The *University Monthly* for March is one of the best numbers of an educational magazine that we have seen this long while. — *Old and New* commends Rolfe's editions of Shakespeare's plays as "an exquisite handy-volume series." — The largest iron casting ever attempted was lately made at Newcastle-on-Tyne, being an anvil block of 125 tons, intended to be used with a 20-ton hammer, in forging Armstrong guns. — Alcoholic solutions of perchloride of iron are not precipitated by carbonate of lime, and may therefore be used, more or less concentrated, for imparting various shades of yellow to white marble. — *Fireside Science* continues to receive the emphatic commendation of the best critics, not only in this country, but in England, where it has been very favorably noticed by the *Saturday Review*. — *Nature*, quoting from Quetelet, says that "the mean man is a little under five feet eight inches in height, and measures about thirty-five inches around the chest;" but we have known some very mean men whose altitude and circumference varied considerably from these figures, and we venture to say that mean men *can* be found of almost any stature or "bust measure," as the dealers in paper patterns phrase it. — M. Delesse has lately

published a paper on "The Oscillations of the Coasts of France;" but who will attempt to describe the oscillations of French politics? — Russia proposes to observe the transit of Venus in 1874, from a chain of stations 100 miles apart, extending from Kamschatka to the Black Sea.

LITERARY NOTES.

PRESIDENT CHADBOURNE, of Williams College, delivered at the Lowell Institute in this city, in 1871, a course of lectures upon *Instinct, its Office in the Animal Kingdom, and its Relations to the Higher Powers of Man.* These lectures have recently been published by Messrs. Putnam & Sons, New York. We have read the book with much interest, as we do all the works of its distinguished author. Although treating upon a difficult and quite abstruse subject, it is made clear and comprehensible to even popular readers, and we think those who seldom open treatises upon any branch of intellectual philosophy will be delighted with its plain and lucid reasoning. The book should go into circulating and Sunday-school libraries, and into families, as it is calculated to exert a salutary moral influence, as well as to improve and enlarge the intellect.

Plain Talk about Insanity, its Causes, Forms, Symptoms, and Treatment, by T. W. Fisher, M. D., formerly connected with the Boston Hospital for the Insane (published by Mr. Alexander Moore, of Boston), is a timely work, as the public interest in the questions regarding the proper treatment of the insane has never been greater than at the present time. There is a growing feeling, both among physicians and sensible, observing men in all the walks of life, that our method of herding the insane together, as we do, in hospitals, is not the best that can be devised. As we intend at some time to discuss this subject in a more extended manner, we will only say that Dr. Fisher's book is well worth reading, and that it contains much that is sensible and worthy of consideration. It can be easily understood by the non-professional reader.

The same publisher has issued *Animal and Vegetable Parasites of the Human Skin and Hair*, by Dr. B. Joy Jeffries. This work presents to the medical profession the results of much study and experience upon a subject which ought to be better understood. However unpleasant the idea may seem, only too many of the human family in the most civilized countries are annoyed or rendered miserable by the presence of animal parasites. It is not alone the poor and the dirty that are troubled with parasites, but the cleanest and wealthiest are often tormented with them to a degree which renders life intolerable. Dr. Jeffries explains what parasites are, where they come from, how they live and thrive on the skin, in the skin, and in the deep tissues of the body. The book is an exceedingly handy little manual, and undoubtedly will find many readers.

Messrs. Scribner, Armstrong, & Co. have published two more volumes of the "Illustrated Library of Travel" which we commended last month: *Wild Men and Wild Beasts*, by that "mighty hunter," Gordon Cumming; and *Arabia*, by Bayard Taylor, an admirable summary of all that travellers have learned concerning one of the least known but most interesting of lands. They have also issued another of the second series of "Wonder Books:" *Wonders of Electricity*, from the French of J. Baile, with valuable additions (especially where the author, after the usual French manner, has ignored foreign inventions and discoveries), by Professor J. W. Armstrong; and the *Memoir of Robert Chambers, with Autobiographic Reminiscences of William Chambers*, in which the latter, as the London *Athenæum* well says, "has told the tale of his own and his brother's heart-rending beginnings with such concentrated clearness, that here may be learned lessons of self-denial, patience, unflagging perseverance, independence, and cheerfulness (the greatest sustainer of all), which comprise a whole education, not only for the humblest in station, but for the least intellectual."

The Harpers have published Vol. III. of *Brougham's Autobiography*, and Vol. II. of *Tyerman's Life of Wesley*, both of which are even more interesting than the preceding volumes, and will be very welcome to numerous readers who have been waiting for them; *Ancient America*, by John D. Baldwin, A. M., which seems to us more valuable for its excellent *résumé* of the facts of American archæology than for its theories and speculations; and two more volumes of the revised edition of Dr. Barnes's "Notes," being those on *First Corinthians* and on *Second Corinthians and Galatians*.

The Appletons have reprinted the revised edition of Sir John Lubbock's *Prehistoric Man*, containing much new matter, and giving the results of the latest investigation on a subject of absorbing interest; *Three Centuries of English Literature*, by Professor C. D. Yonge, which with some minor faults has many great merits, and is likely to be useful to the student as well as the general reader; and *Man and his Dwelling Place*, an Essay toward the Interpretation of Nature, by James Hinton, author of "Life in Nature," "The Mystery of Pain," etc.

The University Publishing Company, who are preparing a series of school-books with special reference to the wants of the South, though by no means exclusively for that latitude, have recently added to their list a *Practical Business Arithmetic*, by L. Fairbanks, A. M., which is very complete and satisfactory, and *How to Draw*, by A. S. Avery, explaining "the right and the wrong way," in a manner that ought to enable the pupil to attain the one and avoid the other with very moderate guidance on the part of the teacher.

TO CORRESPONDENTS.

WE have received several long and interesting communications on "Medical Philosophy," for which we regret that we cannot find room. The subject is better suited to a quarterly review than to a journal like ours, and it would be impossible to do it justice in the space we have at command without doing injustice to a hundred other topics that claim our attention each month.

A friend who has more than once contributed to our columns sends us some comments on our note concerning "Anæsthetics in the Slaughter-house," and suggests that the sufferings of the criminal on the gallows might be alleviated in a similar way. This has been proposed more than once, and there is no novelty in the idea of using anæsthetics in killing animals. The merit of Dr. Richardson's plan is that it furnishes a cheap and safe agent, and a simple and convenient mode of administering it, — which, so far as we are aware, has not been done before.

Two or three communications already in type are crowded out of this number, but will appear in our next.

Medicine.

LATIN AND GREEK IN MEDICAL EDUCATION.

IN the Valedictory Address to the graduating class at Louisville, delivered March 1, 1872, by Prof. R. O. Cowling, there are some judicious remarks on this subject, from which we make the extract below. It should be understood, however, that while the speaker assigns little *practical* value to the dead languages in the training of the physician, he does not underrate them as means of general culture. In the latter part of the address, he strongly recommends them as worthy of study for their own sake, and gives them a prominent place among the studies to be taken up, if possible, after entering upon professional life. This is good counsel, but not one out of a hundred is likely to profit by it.

Is Latin essential to a doctor? I think so. It has been used so long in the nomenclature of our profession that we could not change it if we would. Some years ago they tried in New York to simplify the law by translating the terms, but utterly failed. It was more dignified to say the writ of *ne exeat* than the writ of "no go," and *habeas corpus* than "take his carcass," in which manner the profane were wont to construe these terms. And, besides, Latin is the great catholic bond of medicine. Try it yourselves some time in a foreign land, when you feel cut off from the world by the unintelligible jargon which is sounding around you, and see how sweet it is to know a message for pil. hydrarg. to an apothecary will as certainly bring blue mass in Vienna as here in Kentucky. Besides, this is one of the demands the community makes upon doctors. It does not like vernacular medicine. Paregoric is too bald to pay three dollars for, and next to the tritest pleasantry in medicine — the "distressingly healthy" joke ranks first — is that many a simple Simon whom calomel would slay thrives on the hydrarg. chloridum mite. But grant that Latin is essential, then how much? It has been variously estimated from the Latin grammar up to several books in Virgil. By far the principal part of Latin with which medicine is concerned consists in the terms of anatomy and the materia medica. As to the first, I am sorry to think how little they do bother most men after graduation. In the materia medica which he must so constantly use, it is little else besides the vocabulary which is required, for I take it that he who writes the directions of his prescriptions in Latin must take the pains to translate them. The little that is required beyond the vocabulary is the genitive case. It would indeed be more elegant to use it when required; but I venture to say that not one in a hundred doctors can lay his hand on his heart and declare he was ever guiltless of its omission. Now for this wonderful amount of Latinity, why vex young Galen's soul with the intricacies of the subjunctive mood, or test his engineering skill with Cæsar's bridge, or rouse up his already harassed sensibilities with the sufferings of Æneas?

But because the necessity of a certain amount of Latin is granted, there is no reason why medicine should be saddled with Greek. In these modern days of specialties there is an alarming tendency to this. I wonder if the soothsayers in ophthalmology do not smile together over the terms with which they blind their art. It is certainly not a pleasant thing to have one's eyelids grown together; it is terrible to have it called anchyloblepharon; and bad as is an inflammation of the retina, what is life worth when we know this is amphiblestroidites? Can any one believe that medicine is advanced by such a nomenclature as this? Macaulay has said that one reason why no one knows anything of Indian history is on account of its outrageous names. But the "Bundelcunds" and the "Punjaubs" of that language are as the prattle of children when compared with the tremendous titles with which the modern specialist obscures his art. What a flood of light the pure ray of English would let in! We call the instrument for crushing stones a lithotrite. The Germans more sensibly call it simply stone-breaker. If a knowledge of Greek is to further a barbarous coinage of words, it would be better for medicine that some imperial ukase could abolish it entirely.

He who judges a medical student by the same standard as he would school-boys, knows little of his character. He is not forced to his work; he comes to it in dead earnest. He knows he has so much time, and so much money, and he invests his capital to the best advantage, with an eye to its returns. I have not seen that the Latin or Greek necessary to the understanding of medical terms offered him special difficulty. Indeed it has been a matter of astonishment to me how readily they are mastered by men who had no previous knowledge of these languages.

PRESCRIBING FOR INFANTS.

THE following sensible hints on this subject are from a lecture by Prof. J. O'Reilly, published in the *American Practitioner* for April, 1872: —

There are two points in the general medication of children to which I wish especially to call your attention. One is the subject of thirst, the other is the intervals at which medicine should be given.

In quite a number of infantile diseases the stomach is very capricious, and to keep it quiet is one of our greatest troubles. This difficulty is often caused by the attendant not understanding the difference between hunger and thirst. The sick child is fretful, and cries and pulls at its mother's breast; and she, willing to do anything that soothes it, permits it to nurse. It sucks, and in a few moments rejects the milk; but cries again, and the mother again yields it the breast only to have the stomach again reject its contents, and thus the fight goes on until the infant is exhausted. The doctor gives medicine to quiet the irritable stomach, and the mother counteracts its effect by overfeeding. What I wish to express is the fact that the child is not hungry; it does not want the breast; but is thirsty and wants drink. In health the breast is food and drink, but in disease the craving is that of thirst, not of hunger, and the stomach which rejects the milk because it is unable to digest it would be calmed by a cool beverage. In other words, were water given to the child in the place of the breast, the stomach would be relieved, and in many cases the child saved. This difference between thirst and hunger in the infant is a point well worth noting.

Medicine should be given to infants in small but often-repeated doses. The interval should be only half as long as that for the adult. The reason for this is that the digestive organs of the infant act much more rapidly than those of the adult, and a

medicine to have its effect kept up must be supplied in accordance with its entrance into and disappearance from the system.

HEAT AS A POISON.

One of the French journals gives an account of some curious experiments by M. Claude Bernard on the effects of heat upon animals. It appears from these that heat, when it attains too high a degree, acts like a poison, and destroys feeling and motion. It seems to act directly on the muscular element; and the loss of muscular power necessarily produces death by arresting the action of the heart and circulation. The degree of heat which must not be exceeded for cold-blooded animals is from 115° to 120° F., for mammalia 128° to 131°, for birds 140° to 145°. In each case the maximum differs by a few degrees only from the animal's normal temperature. There is, then, an inward medium, the temperature of which is kept up by that of the blood — a certain atmosphere of heat, so to speak, which should remain unalterable. The artificial increase of this heat leads to the most serious consequences as soon as it exceeds a very few degrees. To what particular poisons, then, can heat be assimilated? Those must be sought which have a direct action upon the contractile muscular element, such as the *antiar* (the milky sap of the *Upas antiar*), the *vas*, and the *corwal*, American vegetable poisons. These substances, probably, have the same chemical action upon the blood as heat. The precise action of heat upon the blood is thus stated by M. Bernard: The blood of an animal killed by heat becomes black, the oxygen it contains is rapidly transformed into carbonic acid, and finally disappears. This is not a true toxical action, but rather an excitement of the vital and normal properties of the red particles. The black blood of the rabbit killed by heat is still living; it absorbs oxygen by contact with the air, and again becomes ruddy, if the experiment is tried in time. Between 167° and 190° F., however, the blood coagulates, loses its vital properties, and cannot again become red. Heat above a certain degree kills the muscles without killing the blood. The chemical character of this poisoning of the muscles by heat is the most obscure part of the subject. It now remains for chemists to analyze the phenomena which accompany the muscular rigidity and cessation of motion produced by heat, and thus to solve the problem of the precise action of this poison, as they have done in the case of certain others.

MEDICAL MEMORANDA.

Bisulphite of Soda in Throat Diseases. — Dr. Tyrrell, in the *Pacific Medical Journal*, commends, as a new remedy in this class of affections, bisulphite of soda, given in large and continuous doses. Diphtheria, inflammation of the tonsils, and quinsy, though local exhibitions, have their source in poisonous fermentations of the blood, the same as scarlet fever and other zymotic diseases. It is held that the salt prescribed enters into the circulation and retards putrefactive fermentation. Dr. T. failed of success when he administered it in small doses and in three hour intervals; but when he gave thirty grain doses every hour, day and night, so as to saturate the system with the salt, he was almost invariably successful in removing all the severe symptoms in twenty-four hours. He asks physicians to give this medicine a trial, that the curative effects may have more extended proofs.

Stag Pills. — Pills "purely vegetable," have been a popular nostrum in this country, but in the Celestial Empire those of a thoroughly animal character appear to be in demand. A Chinese druggist at Ningpo invites the public to swallow "Pills manufactured out of a whole stag, slaughtered with purity of purpose, on a propitious day." The wealthy wholesale druggists are in the habit of purchasing large and handsome stags, which they expose in a pen at the door of the shop until "a propitious day" is selected for the animal's conversion into pills, when he is deliberately pounded entire into pulp, from which pills are made.

The Limit of Longevity. — Sir Henry Holland, in his interesting "Recollections of Past Life" (just reprinted here by the Appletons) refers to the question whether there is any trustworthy evidence of any human life longer than a century. He himself believes that there have been well authenticated instances of the kind. In the report of the Irish Registrar-General for the third quarter of 1871, the deaths of six centenarians are recorded. The Registrar of Cookstown District reports the death of a woman aged 102, and a man 108, and says: "I have made careful inquiry respecting these two cases, and have no reason to think the ages are exaggerated; both are remembered as 'old people' by individuals long past their climacteric." In the Dervock district, Ballymoney Union, the registrar reports "a death at the advanced age of 105 years, authenticated."

It is stated in several medical journals of recent date that "Harvey Thacker, who died recently in California, was 128 years old at the time of his death." If there is satisfactory evidence of this extraordinary longevity, it would be interesting to know more about the case.

Varying Effects of Poisons on Different Animals. — It is a well-known fact that what is poison to one animal may be taken by another with entire impunity. In illustration of this proposition, we are informed that strychnine, so fatal to most animals, may be eaten by certain species of monkeys with perfect safety. In the case of an East India monkey, known as the Lungoor (*Presbytis entellus*), one grain was first concealed in a piece of cucumber, which was eaten by the animal with no apparent effect. Three grains were afterward given, and with the same result. To test the strychnine used, three grains were administered to a dog, which proved almost immediately fatal. Another Indian monkey, known as the pouch-cheek monkey, has been found to be more susceptible than the Lungoor, but not so much so as the dog.

It is also stated that pigeons can take opium in large quantities with no injurious consequence; goats, tobacco; and rabbits, belladonna, stramonium, and hyoscyamus.

Vital Statistics. — The Philadelphia *Medical Times* says, that half of all who live die before seventeen. Only one person in ten thousand lives to be one hundred years old, and but one in a hundred reaches sixty. The married live longer than the single; and out of every thousand born only ninety-five weddings take place. Of a thousand persons who have reached seventy, there are of clergymen, orators, and public speakers, forty-three; farmers, forty; workmen, thirty-three; soldiers, thirty-two; lawyers, twenty-nine; professors, twenty-seven; doctors, twenty-four. Farmers and workmen do not arrive at good old age as often as clergymen and others who perform no manual labor; but this is owing to the neglect of the laws of health, inattention to proper habits of life in eating, drinking, sleeping, dress, and the proper care of themselves after the work of the day is done. These farmers or workmen eat a heavy supper on a summer's day, and sit around the doors in their shirt-sleeves, and, in their tired condition and weakened circulation, are easily chilled, laying the foundation for diarrhœa, bilious colic, pneumonia, or consumption.

A Possible Risk in the Use of Chloralum. — Professor Fleck, of Dresden, in a report upon the products of the English "Chloralum Company," asserts that these preparations contain chloride of lead, copper, and arsenic, therefore that their use is not without danger. He estimates the disinfectant proportional power of chloralum as compared to chloride of lime, to be as 74 is to 100. We also quote the analysis of chloralum liquor published by the Professor. According to this investigation, 100 parts of chloralum contain —

82.32	per cent.	of water.
0.15	"	of chloride of lead.
0.10	"	of chloride of copper.
13.90	"	of aluminium.
0.42	"	of iron.
3.11	"	of calcium, and some sulphate of lime.

In the chloralum powder he declares he has found 0.72 per cent of chloride of arsenic.

First Use of a Mineral Medicine. — The *British Medical Journal* says: "Legend has it that this was the oxide of iron. Melampus, who lived about two centuries before the fall of Troy, holding an augury to discover a cure for impotence, was directed to seek for a certain knife which had lain for a long time in a tree, where it had been stuck after it was used for sacrifice. The rust scraped off this, and given to his patient for ten days in wine, was warranted by a sapient old vulture to effect a cure."

CARBOLIC ACID RECIPES.

Carbolic Toilet Water. — Crystallized carbolic acid, 10 parts; essence of mille-fleurs, 1 part; tincture of quillaya saponaria, 50 parts; water, 1,000 parts. Mix. The saponine replaces soap with advantage. The above should be employed, diluted with ten times its bulk of water, for disinfecting the skin, for washing the hands after any risk of contagion, etc.

The *tincture of saponine* in the above is made by taking of bark of quillaya saponaria, 1 part, and of alcohol (90°), 4 parts. Heat to ebullition, and filter.

Carbolized Amylaceous Ointment. — Pure starch, 3 parts; hot water, 20 parts. Mix in the ordinary way (the starch being made first into a paste with cold water, and then hot water added), to a stiff consistence; then add olive oil, 1 part; glycerine, 3 parts; carbolic acid, 1 part, and thoroughly mix in a mortar. When cool, this is a soft jelly, which can easily be applied as ordinary ointment. It is much more efficacious than one the base of which is entirely fat, and it is an agreeably cool application.

Carbolized Tooth-Wash. — Water, 1,000 parts; essence of meat, 2 parts; tincture of saponine, 50 parts; pure carbolic acid, 10 parts. Mix. A dessert-spoonful, in a quarter of a tumblerful of water, serves as an excellent preparation for cleansing and preserving the teeth.

Carbolized Oil. — Pure carbolic acid, 1 part; olive oil, 6 parts. Linseed oil is sometimes used as a vehicle, but olive oil is preferable, as being less prone to oxidation.

Antiseptic Lead Plaster. — Olive oil, 12 parts (by measure); litharge (finely ground), 12 parts (by weight); beeswax, 3 parts (by weight); crystallized carbolic acid, 2½ parts (by weight). Heat half the olive oil over a slow fire; then add the litharge gradually, stirring continually until the mass becomes thick, or a little stiff; then add the other half of the oil, stirring as before, till it becomes thick again. Then add the wax gradually till the liquid again thickens. Remove from the fire and add the acid, stirring briskly till thoroughly mixed. Cover up close, and set aside to allow all the residual litharge to settle; then pour off the fluid and spread upon cloth to the proper thickness. The plaster made in this way can be spread by machine and kept rolled in stock, and in a well-fitting tin canister will retain its virtues for any length of time.

Carbolic Acid Paper. — This paper, which is now much used for packing fresh meats, for the purpose of preserving them against spoiling, is made

by melting five parts of stearine at a gentle heat, and then stirring in thoroughly two parts of carbolic acid; after which five parts of melted paraffine are to be added. The whole is to be well stirred together until it cools; after which it is melted and applied with a brush to the paper, in quires, in the same way as in preparing the waxed paper so much used in Europe for wrapping various articles.

CARBOLIZED MIXTURE FOR ZYMOTIC DISEASES. — Dr. Alex. Keith advocates the following: Take of carbolic and acetic acids, each from 1 to $1\frac{1}{2}$ f. drachms; tincture of opium, chloric ether, each 1 f. drachm; water, to 8 f. ounces.

A tablespoonful every four hours until the fever subsides.

SMALL-POX ITEMS.

SMALL-POX IN CHINA. — Small-pox is called the "bean disease" in the Chinese language, from the resemblance of the vesicle to a small bean or some other form of pulse, a kind of food very largely grown in China. The disease dates from the reign of the first Emperor of the (Eastern) Han dynasty, Kwang Wu, who reigned A. D. 25–28. It is said to have been imported from some portion of Central Asia, or from some part of Southwestern China now included in the nominal empire, by some Chinese troops returning from a foreign campaign. This adds another instance to the important list of diseases propagated by armies in ancient and mediæval times. Inoculation has been practised amongst the Chinese for a thousand years or more, showing that the disease must soon have clamored for some interference, even at the hands of an Eastern people, strong in their belief in fatalism. This latter failing is attested by the facts that the disease is called the *Tien-hwa*, or "heavenly flower," and that the malady has been deified under the name of "Holy Mother of Small-pox." Temples are erected in every part of the empire in honor of this goddess, and every family visited by the disease sends some worshipper with offerings to the shrine of this old hag.

In order to avoid any offence to her, the disease, one of the most horrible of all afflictions, is spoken of as the "felicitous circumstance," or some other periphrastic or propitiating term. The earliest work on the disease is a kind of treatise called "Wan-jin-shi-tau-chin-lun," first published in 1323. Several other works have been written on the disease; some on inoculation. It is curious that in Chinese the malady is called *Hwa*, the "flower," the equivalent of the word *exanthema*.

SMALL-POX THEATRICALS. — An English paper gives the following account of a theatrical entertainment, which would not have drawn a very full house if it had been dependent upon outside patronage: "The officers of the Hampstead Small-pox Hospital and the convalescent patients have, with the permission of the authorities, fitted up one of the unoccupied wards as a theatre. The opening entertainment consisted of a concert by the patients, and an amateur performance of the farce 'Box and Cox.' Several songs were very well sung by the patients, and the characters in the farce were well sustained by the officers. Two patients performed on the piano and flute, and the audience, consisting of all the patients who were able to attend, and all the officers and servants who could be spared from their duties, are said to have been delighted with their evening's amusement."

TAKING A HORN. — An interesting memento of the discoverer of vaccination has recently been presented to the Royal College of Physicians by Sir John William Fisher. It consists of a cow's horn, beautifully polished, presented to Sir J. W. Fisher, in the year 1813, by Dr. Jenner, and polished by himself. The gift was made in grateful acknowledgment of services rendered to Jenner's sick children by Mr. Fisher, then a medical assistant in Soho. The horn is now mounted in silver, and bears an appropriate inscription stating the circumstances under which it was presented to the College. Dr. Burrows, the President, in asking the acceptance of the horn, stated that it was probable — though there was no record of the fact — that the horn had been taken from one of Dr. Jenner's favorite cows on which he made his experiments on vaccination.

SELECTED FORMULÆ.

COATING FOR PILLS. — The London *Chemist and Druggist* gives the following as an efficient coating for pills: —

℞ Æther	100 parts.
Balsam of tolu	10 parts.
Colophonium	1 part.
Absolute alcohol	10 parts.

Macerate till the resin is dissolved.

Sugar-coated pills may be made by first rolling them in a mortar in the above æthereal solution, and then transferring to a sheet of writing paper with the sides bent upwards, shaking being continued till they are perfectly dry. Then to a small quantity of *saccharated albumen* add a few drops of water, at the same time beating for a short while, so that a thick paste will be formed. Into this mass the pills are stirred, and when moistened on all sides, quickly poured into a wooden pill-box, which has been previously filled about one third with the finest powdered sugar obtainable, and immediately shaken, or rather rolled, in a lively way and with great force, separating from time to time those cohering. When no more sugar will adhere they are dried over a gentle fire, taking care not to bring them too near the stove, lest they should crack. Shaking, of course, must be continued till dryness is effected.

Saccharated albumen (*albumen cum saccharo*) is prepared as follows: Take the white of an egg, and in an evaporating dish beat with it as much powdered sugar, passed through a very fine sieve, as will make rather a thick fluid. Then place it in a water-bath and evaporate to dryness, stirring constantly, that no sugar may be deposited. Pulverize, and set aside for further use.

SCENT POWDER. — The following recipe for scent powder to be used for wardrobes, boxes, etc., gives an article far superior to the mixtures sold in the shops: coriander, orris root, rose leaves, and aromatic calamus, each one ounce; lavender flowers, two ounces; rhodium wood, one fourth of a dram; musk, five grains. These are reduced to a coarse powder. The scent on the clothes is as if all fragrant flowers had been pressed in their folds.

ROSE TOOTH POWDER. — The following is a good formula:

Pulv. Myrrh	
Bi Carb. Soda, aa	℥ij.
Pul. Orris Root	
Pulv. Cuttlefish Bone, aa	℥ij.
Precip. Chalk	℥vi.
Otto Rose	gtt. xv.

Mix, and color with carmine.

CASTOR OIL POMADE. — Mix the following:

Castor Oil	4 oz.
Prep. Lard	2 oz.
White Wax	6 dr.
Oil Bergamot	
Oil Lemon, aa	$\frac{1}{2}$ dr.

DIARRHŒA AND BOWEL CORDIAL. — The following is an excellent formula for a cordial to keep in the household, and was prepared by a physician who has used it with great success in his practice: Chalk mixture, $3\frac{1}{2}$ oz.; tincture of Jamaica ginger, $\frac{1}{2}$ oz.; laudanum, 1 drachm. Mix, and keep in a cool place. Shake the bottle before using. Dose for an adult, one teaspoonful as often as necessary; children, half dose or less.

LINSEED SYRUP. — To make linseed syrup for a cough, boil one ounce of linseed in a quart of water for an hour; strain it, and add to the liquid the juice of two lemons and a half pound of rock candy. If the cough is accompanied by weakness and loss of appetite, add half an ounce of powdered gum arabic. Set this to simmer for half an hour, stirring it occasionally. Take a wine-glass full whenever the cough is troublesome.

FLORIDA WATER. — The *Druggists' Circular* gives the following recipe:

Olei Lavandulæ	2 drachms.
" Bergamot	2 "
" Limonis	2 "
Tinct. Curcum.	1 drachm.
Olei Neroli	1 "
" Melissæ	30 drops.
" Rosæ	10 "
Alcohol, deodorized	2 pints.

LINT. — Next to cotton, the vegetable fibre most extensively used for textile fabrics is flax, the Latin name of which is *linum*, — hence come the names of linen and lint. The fibres of cotton and flax, viewed under a microscope, will be found to be different; the fibre of cotton is angular, or bladed, while that of flax (linen) is perfectly round and smooth. It is this difference in their natural formation that constitutes the superiority of linen over cotton as a material for dressing wounds, or as a fabric for clothing the body. Lint is the unwoven fibre of linen. By wear, and much washing, which it necessarily undergoes, linen becomes softer than when new; it undergoes a partial decay, and the much-prized linen eventually becomes "rag." In this state it is fit only to be converted into paper or lint. Lint is, in fact, the woolly fibre of old linen, "thrown" or slightly "felted" together (as manufacturers term it) into the material form so named. The flax plant yields not only linen by means of its fibre, but it also, by expression, gives a valuable oil from its seeds, known in commerce as linseed oil. The residue, after the oil is expressed, is called linseed cake, and is excellent food for cattle. Each product of the flax plant, both in peace and in war, has its value either as linen, linseed, or lint. — *Scientific American.*

PRIMITIVE MEDICAL PRACTICE. — A gentleman in Alabama, in exerting himself one day, felt a sudden pain, and fearing his internal machinery had been thrown out of gear, sent for a negro on his plantation, who made some pretensions to medical skill, to prescribe for him. The negro, having investigated the case, prepared and administered a dose to his patient with the utmost confidence of a speedy cure. No relief being experienced, however, the gentleman sent for a physician, who on arriving inquired of the negro what medicine he had given his master. Bob promptly responded:

"Rosin and alum, sir."

"What did you give them for?" continued the doctor.

"Why," replied Bob, "de allum to draw the parts togedder, and the rosin to sodder um."

The patient eventually recovered. — *Banner of the South.*

HOMER ON PHYSIC. — DOCTRESS THETIS. — Anæsthesia has been traced as far back as the exsection of the rib in the garden; and now comes a writer in the *N. Y. Medical Journal*, claiming for Homer a knowledge of the art of embalming. When Patrocles, a friend of Achilles, was slain, according to the Iliad, the body was washed and anointed with ointment nine years old, and laid on a bed and covered with fine linen from head to foot; and over all was spread a white mantle. The next day Thetis came and made a *post-mortem* injection into the body in order to preserve it, "and then she instilled into it through the nostrils ambrosia and ruby nectar, that his body might be uncorrupted." Thetis would appear to have been the first female physician. — *Pacific Med. and Surg. Journal.*

Familiar Science.

THE HOLTZ ELECTRICAL MACHINE.

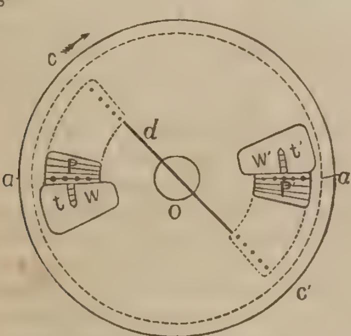
BY PROF. C. A. YOUNG.

UNQUESTIONABLY, one of the most remarkable of the scientific instruments which have originated within the last few years is the Holtz Electrical Machine, so named from the German physicist who invented it in 1865.

Those of our readers who have enjoyed the advantages of academy, high school, or college, probably recollect the old machines, in which the electricity is slowly produced by the laborious friction of a glass plate or cylinder upon a rubber coated with an amalgam of mercury and tin. In the new machine, on the contrary, the electricity is produced in quantities perfectly amazing to one familiar only with the old apparatus, and, without friction at all, solely by induction, or *influence*, as the Germans call it; indeed, in Germany, the instrument is commonly known as the "Influenz-electrir-maschine."

As originally devised by Holtz, the construction was essentially the following, though in the hands of different makers it has received various forms: —

By means of a pulley and multiplying wheel, a thin glass disc, varnished with shellac, and from 15 to 30 inches in diameter, is made to revolve swiftly behind a fixed plate of a little greater diameter, also of thin glass varnished, and as close to it as possible, without actually touching.



In the fixed plate two "windows" are cut out, as shown in the figure at w and w'. On the *front* side of this plate (remote from the revolving plate) are pasted two coatings or "armatures" of thin paper (indicated by p and p' in the diagram), just at the edges of the "windows," and to these paper armatures are attached two pointed tongues of card-board, t and t', which extend into the centre of the window spaces. The axis of the revolving disc passes freely through the centre of the fixed plate, which is perforated for the purpose at o.

Just *behind* the revolving plate, and opposite the paper armatures, are placed two "collecting combs," each consisting of a row of sharp metallic points directed towards the plate, indicated by the rows of dots at a and a' in the figure. These combs receive the electricity generated, and by suitable connections convey it to a pair of insulated conductors (not represented in the diagram), from which the sparks are obtained. Usually the conductors are provided with a pair of sliding brass rods, having knobs at each end to serve as electrodes, which can be pushed into contact, or separated to any desired distance.

The machine is put into operation by bringing the knobs together, and holding near one of the armatures a piece of ebonite previously electrified by rubbing with a cat-skin; a piece of glass, electrified by friction with silk, answers nearly as well. Then, if the air is thoroughly dry, on putting the plate into rotation in the direction of the arrow, a very few seconds will bring the machine into a state of intense excitement.

The plate, which before turned with perfect freedom, will move somewhat stiffly, as if it encountered a resistance; a peculiar rushing noise will be heard, a strong odor of ozone will be perceived, and if the room be dark, most beautiful fringes and stars of light will appear upon the points of the combs and the card-board tongues. When the machine is once in operation, the exciting ebonite may be taken away, and the activity will continue as long as the rotation is kept up.

On separating the electrodes a few inches, but not too far, a continuous stream of sparks will play between them, and if they are connected each to one of the coatings of a Leyden jar, the sparks will become intensely brilliant, though shorter and less frequent.

But although the power of the machine, even in this form, far surpasses anything before known, it is subject to some serious inconveniences. It is not possible to obtain from it sparks more than four or five inches long; and if the knobs are separated to a distance ever so little exceeding the striking limit, the machine almost instantly loses its activity, and must be excited anew. The same thing happens if it be allowed to stand unused for fifteen or twenty minutes.

These difficulties have been almost entirely removed by a slight modification introduced by Poggendorff a little more than two years ago. He extends the paper armature over an arc of about 60°, as indicated by the dotted lines in the figure, and adds a second pair of combs at c and c', which are connected to each other by the "diametral conductor" d — merely a stout brass wire.

Thus modified, a machine with a 16-inch plate, from which, under the former arrangement, nothing more than a 2½ or 3-inch spark could be obtained, gives easily 7 or 8 inches; the machine does not lose its activity, however widely the electrodes are separated (it is not necessary to bring them into contact even to excite it); and it may stand unused for hours in a dry room, and yet be ready to start at once into full action with a few turns of the crank.

The beautiful little instruments of this size, which Ritchie of Boston now sells for $35, are far more effective than the imposing machines with plates from 2½ to 3 feet in diameter, which twenty years ago used to adorn our apparatus rooms at prices ranging in those days of cheapness from $100 to $200. All these "influence machines," however, require for their successful working a dry atmosphere, and they are perhaps a little more sensitive in this respect than the frictional machines which they supersede.

More recently Poggendorff has combined these machines in pairs, with the best results. He puts together two such machines, driven by a single crank, back to back, at a distance of about a foot, having between them the ebonite insulating pillars, upon which the electrodes are mounted.

A machine of this description, made by Borchardt of Berlin, for Dartmouth College, with plates only twenty inches in diameter, gives simple sparks from 12 to 13 inches long, and Leyden-jar sparks of 9½ inches. The two Leyden-jars, mounted upon the top of the electrodes, are made of glass very nearly ½ inch thick, and have each a coated surface of about ⅔ of a square foot.

Ordinary jars of thinner glass, and exposing about one square foot of coated surface, are fully charged and discharged with a spark 2 inches long 75 times a minute. The frictional machine belonging to the college, — a very fine one of its class, with a plate 34 inches in diameter, — under the most favorable circumstances, can be made to do the same between 3 and 4 times a minute. The new machine is therefore something more than twenty times as powerful, and the labor of working it is incomparably less.

As yet these machines have not found any important technical application. Ozone, however, is already used to some extent in bleaching operations, and they furnish such quantities of this gas, with so little expenditure of power, that it would seem quite likely they may be made useful in this direction.

A discussion of the theory of their action would be unsuited to these pages; indeed, though in the main this theory is simple enough, and easily understood by any one acquainted with the laws of electrostatic induction, there are some peculiarities in their behavior which are not yet satisfactorily explained, and may require for their elucidation the discovery of some new law of electrical action.

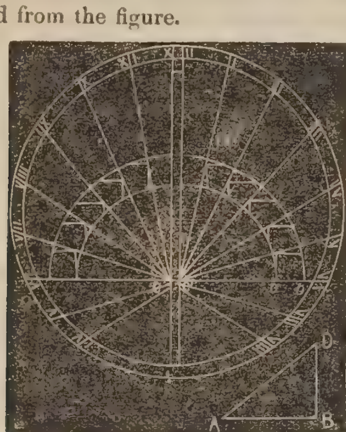
DARTMOUTH COLLEGE, *April* 2, 1872.

SUN DIALS.

A VERY pretty ornament for pleasure grounds, and one that is sure to attract a great deal of attention, is a sun dial. Any person with a little mechanical ingenuity may easily construct one that will give the time on bright days to within a very few minutes of the true time, though

of course this, being solar time, will differ from mean or clock time.

Sun dials may be vertical, horizontal, or equatorial. The latter is the most simple form, and consists of a circle divided into twenty-four equal parts, and so placed that its plane shall be parallel to the plane of the equator. The *style* is a fine wire perpendicular to this plane, or parallel to the line passing through the poles of the earth. The circle must of course be divided on both sides, as one half the year the sun will illuminate one side, and the other half the other side. The form in most common use, however, is the horizontal. In this the upper edge of the style is used for casting the shadow, and is made parallel to the lines passing through the poles, or in other words forms with the horizontal plane an angle equal to the latitude of the place. The construction of the dial will be readily understood from the figure.



First, construct the triangle ABD, making the angle at A equal to the latitude of the place. For instance, at Boston it would be equal to about $42\frac{1}{3}$ degrees.

Then at any convenient distance, such as B, make the angle B equal to a right angle.

Draw two parallel lines on the plate that it is wished to divide, at a distance apart equal to the width of the style, and through the points C and C', which may be one fourth the diameter from the centre of the plate, draw the line VI–VI perpendicular to these two lines; this gives the six o'clock line, the double line giving the twelve o'clock lines. Then with a radius equal to AD, draw quadrants from the points C and C' as centres; also draw quadrants with the radius AB from the same centres. Divide the quadrants into six equal parts. From each of these divisions on the outer quadrant draw lines parallel to the six hour line, and from each of the points on the inner draw lines parallel to the 12 hour line; through the point of intersection of these two lines draw lines from the centres C and C'. These will give the hour marks. In order to put the dial into position, it must be placed so that the 12 hour lines are parallel to the meridian; this may be readily done with a surveyor's compass, if the variation of the needle is known; or it may be adjusted at night, when the pole-star is visible, by placing it so that the style points directly towards it. A third method is to take a piece of board, and draw a number of concentric circles on it, and fix it firmly on the dial support; then drive in a short piece of wire in the centre of the board, so that it shall project above it three or four inches. This wire must be perpendicular. Now, observe it in the morning, and mark the places where the shadow of the end of the wire just touches in turn the various circles; repeat this observation in the afternoon. Bisect the chords connecting the two points on the same circle, and draw a line from this point to the centre of the circle; this will give the meridian line. By observing several circles and taking the mean of all the observations, the result will vary but little from the truth. The board may now be removed, and the dial placed in the same position. The style is made with the same angle as the triangle ABD, and is placed so that the angle A coincides with the six hour line. B falls a little short of the twelve hour mark. The marks for seven and eight in the evening, and four and five in the morning, are continuations of the corresponding morning and evening hours.

MICROSCOPICAL INVESTIGATION.

In the essay upon Vinegar in the March No. of the Journal, is found the following paragraph, to which Mr. Charles Stodder of this city appends some interesting comments: —

"How they ['ferment globules,' or the yeast plant] act, in the work of breaking up organic compounds like sugar, is not precisely understood. It is difficult to closely investigate the changes under the microscope, as the evolution of bubbles of carbonic acid in the saccharine solution is so copious that observation is in a great measure cut off."

That the work of "breaking up organic compounds," can ever be understood, explained, or seen under the microscope, is very problematical, but as yet there is no evidence before the public that the research has been conducted with the best modern resources of the microscopist. With one instrument of investigation, the inverted microscope, the object will be not under the microscope, but the microscope under the object. With this instrument the evolution of the gas will interfere much less with the observation of the processes going on. Then, most of the published accounts of investigations of this kind, in France and Germany, appear to have been made with instruments of the construction of ten, fifteen, or twenty years ago, with powers of 400 to perhaps 1,000 diameters. Now, *immersion* objectives of $\frac{1}{16}$ to $\frac{1}{50}$ of an inch focus, giving with ease powers from 1,600 to 10,000 diameters, are in constant use. It is not known that such instruments have ever been applied to this class of studies. They have given remarkable results in other investigations, and until they have been applied to the yeast plant, "morbid or germinal growths," etc., we do not and cannot know all that may be learned about them. It is with such instruments of the better quality that these organisms will have to be studied. Interest in microscopy is rapidly growing in this country. Hundreds of young men have procured their instruments. Here is a branch in which almost everything is yet to be learned, and fame and honors will be the reward of those who add to human knowledge.

Very few European microscopists, when publishing their results, ever describe the instruments they work with; as a general thing they merely say the object was magnified so many diameters, forgetting, or often not knowing, that 500 diameters with one instrument may be vastly inferior or superior to the same power with an instrument by another maker. Astronomers always record and publish the instrument *their* observations are made with. The microscopist ought to do the same. He should give the maker of his objective, its angular aperture, and *real focus*, not merely what the maker sold it for; for it is now a well-known fact that the instruments of some of the most renowned makers are really very different things from what the makers call them. In fact, in the words of Dr. W. M. Carpenter, "$\frac{1}{4}$'s are often $\frac{1}{5}$," and in the words of Mr. F. H. Wenham, "$\frac{1}{8}$'s are often $\frac{1}{9}$ or $\frac{1}{10}$, and sometimes $\frac{1}{12}$!" Thus the makers may obtain a reputation for the performance of a low power to which they are not entitled. C. S.

THE NATURE AND OPERATIONS OF INSTINCT.

The following is a summary of the leading points of Professor Chadbourne's Lowell Lectures on *Instinct* (noticed in our last number), with some of the illustrations given under the various heads: —

The nature of Instinct is not defined till its manifestations have been carefully investigated in all their diversity of modifications. It is at length defined to be "an impulse to a particular kind of voluntary action which the being needs to perform as an individual or representative of a species; but which he could not possibly learn to perform before he needs to act." It "includes all the original impulses, excepting the appetites;" and also includes "that knowledge and skill with which animals are endowed, which experience may call into exercise, but which it does not give." The appetites are regarded as functional and as proper conditions for the activity of certain instincts.

The operations of instinct are simulated in inorganic nature, and on a still higher scale in plant life. The Catch-fly pours out a sticky fluid which holds the smaller insects. The Venus's fly-trap puts forth leaves fashioned to act like barbs for holding their prey. The Pitcher-plant beguiles insects down into its deep cavern along hairs pointing downward that hinder retreat. The provisions for the fertilization of plants, for the diffusion of the seeds, and for the securing of them in places favorable to their germination and development, are in many cases exceedingly like instinct. Plants, like some animals, even become protectors to other species of life: as the oak forms a gall or oak-apple which serves as a home and food for the gall-fly.

The first connection of Instinct with these instinct-like processes is seen in the provision for the nourishment of the young animal life. The raising of the head and the opening of the bill to receive food by the young robin, to which the act of the parent bird in supplying the food is a corresponding act of instinct, is an example.

Pure instinct needs no experience. It goes before to preserve life until knowledge from experience is possible. It works by a wisdom of which its possessor has no apprehension. The theory of transmitted skill involves an ancestry certainly of marvellous ingenuity. How did they come by it? How did the species survive till these geniuses appeared? The theory of natural selection accounts for the survival of the fittest; but how does it account for that characteristic in the animal by which it preserves itself? Hibernating animals feed voraciously in the autumn, when food is abundant, and accumulate fat to an unwonted degree; instinct then leads them to their winter's retreat, when the whole vital activity is so reduced that life is maintained for months without food. How were the species preserved till the changes in structure and function corresponding to these hibernating habits were effected? Then we find some species of animals dependent for their preservation on other species. The caw-bird lays its eggs in the nests of other birds. The owner of the nest hatches the eggs and nourishes the young as its own. When mature, the foundling forsakes its home and all the birds it has ever known, to seek its own species, hatched in scattered nests, and mates and lives henceforth with them. Darwin tries to account for the hexagonal cell of the bee on the principle of economy. The bee wishes to save as much as possible of honey from going into wax. But

the question is, how came the bee to be a builder at all? Nor does the existence of the instinct to build such cells turn on the continuance of bee-life through the winter, as Darwin would have it. For some wasps, that perish every fall, leaving only eggs to perpetuate the species, build mathematical cells like honey bees.

Instinct is not infallible. It may be deceived. Flies lay eggs upon the carrion-plant, which has the odor of putrid flesh. Very young birds open their bills when any sound is made upon the edge of the nest. The hen mistakes a crystal of salt for gravel.

Animals learn from experience. The elephant, that has broken through a bridge, fears to trust himself upon another. The wild squirrel, when first caught, trembles with fear; he learns to trust his captor implicitly. The fox will dig out his trap and spring it, and then take all the bait. Animals also remember; they love and hate; they have an executive power of will. Man has instincts. The difference between man and the animal creation below him is, that in him intelligence rules instinct, while in them instinct rules intelligence. In animals instinct is the proper guide because the highest; in man instinct needs control. Man, besides, has higher instincts than animals. He has the sense of obligation, the grand instinct on which morality grounds itself. He has the sense of a relation to a higher being than himself. He has thus not only moral but religious instincts.

CURIOUS EXPERIMENTS WITH ICE.

Professor Bottomley, of Glasgow University, in a recent lecture to his class, placed a lump of ice as large as an apple on a piece of wire gauze, and on this a board, weighted with 12 pounds. Before the conclusion of the lecture, a considerable quantity of ice was found on the lower side of the gauze, firmly united to that above, though apparently forced through the meshes in a room at 15°C. (59°F). In a second experiment he placed a block of ice on two parallel boards near together, passed a loop of wire over the ice, and hung weights on the ends. Various sizes of wire were tried, and in the final experiment, a wire one tenth of an inch in diameter was used, weighted with 56 pounds. It passed entirely through the block of ice, and fell upon the floor; but this block of ice, though the plane of passage was clearly marked, was not divided, nor could it be split in this plane with a knife and chisel.

This remarkable result he explains to be a consequence of Thomson's theory of *regelation.* The stress upon the ice, due to the pressure of the wire, gives it a tendency to melt at the point in contact with this wire, and the ice, in the form of water intermixed with fragments and new crystals, moves so as to relieve itself of pressure. As soon as any portion of the mass is thus relieved, freezing takes place throughout it, because its temperature is reduced below that of the freezing point of water at ordinary pressures, by melting of contiguous parts. The obvious tendency of the ice under the pressure from above is thus, by a series of meltings and re-freezings, to allow the passage of the wire and yet remain a solid block.

NOTES ON SCIENTIFIC TOPICS.

The Vapor of Mercury. — Mercury is a very peculiar liquid, and it has been supposed that its vaporization presented some exceptional phenomena. Faraday considered that the metal ceased to give off vapor at a temperature of —7° C. (19.4° F.), and that at higher temperatures the vapor — contrary to the general law of diffusion of elastic fluids — forms a very thin layer over the surface of the liquid. The matter has lately been investigated anew by M. Merget, and the results are given in a paper published in the *Comptes Rendus.* He first attempted to find a reagent of greater delicacy than gold-leaf, which was the material employed by Faraday as the test of the presence of the metallic vapor. He finds that paper washed over with an ammoniacal solution of nitrate of silver, or with chloride of gold, platinum, palladium, or iridium, is capable of indicating the presence of infinitesimal traces of mercury, the action of the latter on either of the above metallic salts being to reduce the metal of these compounds, and thus form a more or less intense stain on the paper. By aid of this delicate test he has proved: "(1) that the vaporization of mercury is a continuous phenomenon, that it does not even cease on the solidification of the metal; (2) that the vapor possesses considerable diffusive power, which, though not measurable with exactitude, appears to attain a limit little short of that assignable to it by the dynamical theory of gases; (3) that like other elastic fluids, mercury vapor condenses on such substances as carbon, platinum, etc., which exert no chemical action on it, and that it passes with great facility through porous bodies, such as wood, porcelain, etc." M. Merget discusses numerous practical applications of the above principles, more especially "a method of photography without light," based on the above reducing action exerted by mercury on salts of certain metals.

A Substitute for the Spectroscope. — Herr Lommel has devised three very simple instruments, which, in his opinion, can be used, instead of the spectroscope, for the detection of substances by their colors or colored flames. He calls these the *erythrophytoscope*, the *erythroscope*, and the *melanoscope*, — names *not* very simple, nor, with the exception of the second, specially significant as Greek derivatives. In the first, two colored plates of cobalt blue and dark yellow oxide of iron glass are laid upon each other, and, by inserting them in black pasteboard, with a slit for the nose, something like a pair of spectacles is made of them. The combined glasses are only transparent for the ultra red, for yellow green, for blue green, and blue rays; and they cut off all other colors. Substances known to possess these colors, or to impart them to the flame of a spirit lamp or Bunsen burner, can be detected by viewing them through such spectacles. The *erythroscope* (that is, *red-seer*) consists of a cobalt glass and ruby glass, which allows only the ultra red, beyond Fraunhofer's line B, to pass. The third combination, called the *melanoscope*, consists of a dark red and clear violet glass, through which only the middle red tints can pass. Any one who possesses the facility of alternately using the right and left eye could employ two combinations at once, and thus cover nearly the whole length of the spectrum. For the use of students in laboratories, the inventor believes that this arrangement could be frequently employed for the detection and separation of a large class of bodies which give characteristic colors to flames; and that, by practice, the learner would soon be able to assign the true position to each color nearly as well as if he used the scale usually attached to the spectroscope. We doubt, however, whether the contrivance will prove of so much practical value as Herr Lommel anticipates.

Thermometrical Experiments. — The Providence *Journal* describes the following interesting experiments made in that city with an excellent glass-mounted thermometer.

In the house, with open windows, it stood at 90.2°. Out of doors in the shade, at 95°; freely suspended in the sun, six feet above the greensward, 99.5°. In the same position, with wet bulb, 79.9°: with bulb covered with black silk, 109.96°. When laid upon the grass in the sun, it rose to 104°. Laid upon white cloth, placed upon the grass, 105.0°, and when similarly placed upon black silk it indicated 113°.

The experiments with different colored coverings show very conclusively the utility of light-colored clothing for those who are obliged to be exposed to the direct range of the sun at high temperatures; and the experiment with the wet bulb shows as clearly the value of free perspiration in keeping down the temperature of the body, which, however, the observer finds in his own person, notwithstanding the perspiration while making these experiments, to have risen to 100.5°, which is about two degrees above the usual standard for cooler days. The average temperature of the healthy human body throughout the year, in temperate climates, is 98.4°; while in tropical regions it is about one degree higher.

Spontaneous Generation. — The controversy concerning the possibility of the development of low forms of organic life from inorganic matter still continues. Volumes have been written on the subject, and many more will doubtless be written before the contest comes to an end. "The issue of the question," as the *Christian Union* remarks, "has no direct bearing upon theology. Christian philosophers are too enlightened now to accuse the microscopist or chemist of atheism and blasphemous ambition to become a creator, because he watches the conditions of the activity in nature of the Power which we believe to be divine. This absurd denunciation has been indulged; but we have grown wiser in regard to the true spirit of science. If certain inorganic matters brought together under certain conditions will give rise to life, the experimenter who brings them together is no more a creator of life than if he introduced organic germs to produce it. In both cases he is merely an observer."

It is a curious fact, by the by, that when Redi, in the seventeenth century, promulgated the doctrine that life can only proceed from life (*omne vivum ex vivo*), he was accused of contradicting the Scriptures, which asserted that bees were generated from the body of a dead lion.

Our readers may thank us for defining some of the polysyllabic names by which the various theories on this subject are known. *Biogenesis* is the general term for the production of life from life; it includes *homogenesis*, or the reproduction of similar forms, *xenogenesis*, or the generation of something foreign and permanently different from the parent form, and *heterogenesis*, which is properly the same as the foregoing, but has been used to denote the production of different kinds of young. *Abiogenesis*, or the origin of life without antecedent life, is the better term for "spontaneous generation." Dr. Bastian employs for the assumed origination *de novo* of certain monads the term *archebiosis*.

HOUSEHOLD HINTS.

To Restore Scratched Furniture. — Scrape one pound of beeswax into shavings in a pan; add half a gallon spirits turpentine, and one pint linseed oil. Let it remain twelve hours, then stir it well with a stick, into a liquid; while stirring, add one quarter pound shellac varnish and one ounce alkanet root. Put this mixture into a gallon jar, and stand it before the fire, or in an oven, for a week (to keep it just warm), shake it up three or four times a day. Then strain it through a hair sieve and bottle it. Pour about a teaspoonful on a wad of baize, go lightly over the face and other parts of mahogany furniture, then rub briskly with a similar wad dry, and in three minutes it will produce a dark brilliant polish unequalled.

Another preparation may be made as follows: Make a mixture of three parts linseed oil and one part spirits of turpentine. It not only covers the disfigured surface, but restores wood to its original color, and leaves a lustre upon the surface. Put on with a woolen cloth, and when dry, rub with woolen.

A Noiseless Way of Feeding a Coal Fire. — You know what a racket is caused, even by the most careful hand, in supplying coals to a grate or stove, and how, when the performance is under-

taken by Biddy, it becomes almost distracting. If you don't remember, take notice the first time you are ill, or you have a dear patient in your care, or the baby is in a quiet slumber. Let some one bring on her coal scuttle or shovel, and revive your recollection. Well, the remedy we suggest is to put the coals (or coal?) in little paper bags each holding a shovelful. These can be laid quietly on the fire, and as the paper ignites, the coals will softly settle in place. You may fill a coal-scuttle or box with such parcels ready for use. For a sick room, a nursery at night, or even for a library, the plan is admirable. Just try it. Besides, it is so cleanly. If you don't choose to provide yourself with paper bags, you can wrap the coals in pieces of newspaper at your leisure, and have them ready for use when occasion requires. — The above suggestion from an exchange is worth making a note of.

Hard and Soft Water for Cooking. — The effects of hard and soft water in cooking vegetables vary materially. Peas and beans cooked in hard water, containing lime or gypsum, will not boil tender, because these substances harden vegetable caseine. In soft water they boil tender, and lose a certain rank, raw taste, which they retain in hard water. Many vegetables (as onions) boil nearly tasteless in soft water, because all the flavor is dissolved out. The addition of salt often checks this (as in the case of onions), causing the vegetables to retain the peculiar flavoring principles, besides much nutritious matter which might be lost in soft water. Thus it appears that salt hardens the water to a degree. For extracting the juices of meat to make a broth or soup, soft water, unsalted and cold at first, is best, for it much more readily penetrates the tissues; but for boiling meat where the juices should be retained, hard water or soft water salted is preferable, and the meat should be put in while it is boiling so as to seal up the pores at once.

Fastening Loose Window Sashes. — The most convenient way to prevent loose window sashes from rattling when the wind blows, is to make four one-sided buttons of wood, and screw them to the stopes which are nailed to the face-casings of the window, making each button of proper length to press the side of the sash outwards when the end of the button is turned down horizontally. The buttons operate like a cam. By having them of the correct length to crowd the sash outwards, the sash will not only be held so firmly that it cannot rattle, but the crack which admitted dust and cold air will be closed so tightly that no window-strips will be required. The buttons should be placed about half way from the upper to the lower end of each stile of the sashes.

Cucumber Salad. — A lady correspondent of *Hearth and Home* says: "We have just prepared our winter's supply of cucumber salad, and this is how we made it: There were about a dozen ripe "White Spine" cucumbers lying on their vines, and these we picked, washed, pared, cut into strips, taking out the seeds, and then to each dozen cucumbers — which we cut up into pieces like small dice — we put twelve large white onions, chopped, six large green peppers, also chopped, one quarter pound each of black and white mustard seed, and a gill of celery seed. These were all mixed together, a teacup of salt added, and they were then hung up in a cotton bag to drain for twenty-four hours. Then the salad, with enough clear cold vinegar added to cover it, was put into stone jars and fastened nearly air tight. In six weeks it will be fit for use. It looks as well as it tastes, so white and crisp, and makes an elegant salad for a joint of cold meat. It is not like the Spanish salad, that requires 'a counsellor for salt, a miser for vinegar, a spendthrift for oil, and a madman to stir it up,' but it is quite as good in its way, and not very troublesome to make."

The Arts.

ALLOYS OF COPPER AND ZINC.

These two metals will mix with each other in all proportions. The color of the alloy varies with the proportion of zinc present, from almost copper red to zinc white. The alloys are made by mixing granulated copper and zinc in proper amounts, placing the mixture in black lead or Hessian crucibles, and putting these in a suitable furnace. The alloy must be removed as soon as melted, since by exposure to a high temperature it loses zinc.

Several of these alloys have received distinctive names. *Pinchbeck* contains 6 or 7 parts of zinc to 93 or 94 parts of copper. It has a reddish color, resembling red gold, and was formerly much used for cheap watches and jewelry. When pale gold became fashionable, the alloy was also changed, and it was called *oreide;* this consists of 10 parts of zinc to 90 of copper. Another alloy which is frequently used as a base for gilded articles is called *tombac*, and contains from 20 to 30 parts of zinc, and 70 to 80 of copper. *Dutch gold*, which is used for imitation of gilding, is composed of 14 parts of zinc, and 86 of copper. This is malleable, and can be hammered into very thin sheets.

Brass contains 33.3 parts of zinc, to 66.7 parts of copper, varying, however, somewhat from those proportions according to the use that is to be made of it. It has several advantages over pure copper, besides being cheaper. It is much easier to work in the lathe, being harder and not so tough. It will also make perfect castings, which are hard to obtain from pure copper. A little lead is frequently added to brass, as it is not so tough, and does not clog the file, when containing about one per cent. of this metal. *Prince metal* and *mosaic gold* are of the same composition as brass.

Ormolu contains equal parts of copper and zinc. *Muntz* or *yellow metal* differs from other brass in that it may be rolled when hot; it contains 40 parts of zinc to 60 of copper. The ordinary hard solder for brass may be made by melting two parts of brass with one of zinc.

Sterro metal contains, besides copper and zinc, a little tin and iron; it is very hard, and has been proposed as a substitute for yellow metal in sheathing ships. *Mallet's brass*, which is used for protecting iron from oxidation, contains 25.4 parts of copper, to 74.6 of zinc.

MEMORANDA IN THE ARTS.

Iron Ship-Building in Denmark. — The building of iron ships appears to be rapidly becoming an important branch of industry in Denmark. Although for the last fifteen years small iron vessels, designed for trading between the various Baltic ports, have been built at Copenhagen, it is only recently that the construction of large steamers has been attempted. At present several of 1,000 tons are being built, and one of these, it is stated, will be employed in laying down the telegraph cable between China and Japan. Two steamers, each of nearly 900 tons — the *Rolf* and the *Thorwaldsen* — have just made the passage to New York, and these are said to be the first iron vessels built in Denmark which have ever entered that port.

Iron-Clads at a Discount. — It has been suggested that the admirers of the old wooden line-of-battle ship, with its hearts of oak, and the thousand memories that song and romance have helped to endear, will pluck up spirit again from a rather provoking accident that has happened to one of the best of the British iron-clads. The *Hotspur*, commanded by Lord John Hay, was run into by what the *Army and Navy Gazette* describes as an "old Dublin pig-boat," and besides having her ports and boats carried away, "was mauled so severely" as to be obliged to put into harbor for repairs. The old pig-boat, on the other hand, appears to have sustained no injury at all, and went on her way without any difficulty. It will be remembered that at the battle of Lissa the most formidable iron-clad in the Italian Navy was run down and sunk by Admiral Tegethoff in a wooden vessel. The same thing, if we mistake not, occurred in our own war. It would seem, therefore, that iron-clads are not yet invincible even to unarmored antagonists.

A Big Clock. — The clock on the Parliament Houses in London is the largest in the world. The four dials of this clock are twenty-two feet in diameter. Every half minute the point of the minute hand moves nearly seven inches. The clock will go eight and a half days, but it only strikes for seven and a half, thus indicating any neglect in winding it up. The pendulum is fifteen feet long, the wheels of cast-iron, the hour bell is eight feet high and nine feet in diameter, weighing nearly fifteen tons, and the hammer alone weighs more than 400 pounds. This clock strikes the quarter hours, and by its strokes the short-hand reporters in the Parliament chambers regulate their labors. At every stroke a new reporter takes the place of the old one, whilst the first retires to write out the notes he has taken during the previous fifteen minutes.

Bleaching Ivory. — Ivory is bleached by exposure to sunlight. For piano makers and others, it is prepared by first sawing it into thin sheets or plates. These are placed on suitable frames under glass, and exposed to light for several months. The frames are of peculiar construction and patented. They are so arranged as to shift, thus reversing the exposure of the ivory, so that both sides may be duly acted upon by the light.

The Petroleum Supply. — The London *Chemist and Druggist* remarks that, however soon the English supply of coal may be exhausted, it is certain that the world contains petroleum enough to last until the grandchild of the latest born baby shall no longer care for light or heat. It has not been thought necessary to carry the calculation farther, for the most strained courtesy would hardly insist that we should interest ourselves in a generation remoter than the one we have named. The oil is at present obtained from a certain limestone, which is to be found throughout the United States, and it is highly probable that if this should ever be exhausted, a still more abundant supply will be found in other strata. It would not seem that the petroleum originates in this limestone, but that the latter is merely saturated with it. In the neighborhood of Chicago there are enormous deposits of this oil-bearing limestone. The least thickness of the mass is thirty-five feet, and it has been estimated from experiment that each square mile of it contains 7⅜ million barrels, each of forty gallons, of petroleum. As a means of comparison, it may be stated that the total product of the great Pennsylvania oil-region from 1860 to 1870 was twenty-eight million barrels. Four square miles of the Chicago limestone contain a greater quantity.

Keeping Fish Fresh with Sugar. — A method adopted in Portugal for preserving fish consists in removing the viscera and sprinkling sugar over the interior, keeping the fish in a horizontal position, so that the sugar may penetrate as much as possible. It is said that fish prepared in this way can be kept completely fresh for a long time, the savor being as perfect as if recently caught. A tablespoonful of sugar is sufficient for a five-pound fish.

GOLDEN RECIPES.

GOLD POWDER. — Gold powder for gilding may be prepared by putting into an earthen mortar some gold leaf, with a little honey or thick gum water, and grinding the mixture till the gold is reduced to extremely minute particles. When this is done, a little warm water will wash out the honey or gum, leaving the gold behind in a pulverulent state.

Another way is to dissolve pure gold, or the leaf, in nitro-muriatic acid, and then to precipitate it by a piece of copper, or by a solution of sulphate of iron. The precipitate (if by copper) must be digested in distilled vinegar, and then washed (by pouring water over it repeatedly), and dried. This precipitate will be in the form of a very fine powder. It works better, and is more easily burnished than gold leaf ground in honey as above.

GOLD VARNISH. — Turmeric, 1 drachm; gamboge, 1 drachm; oil of turpentine, 2 pints; shellac, 5 ounces; sandarac, 5 ounces; dragon's blood, 7 drachms; thin mastic varnish, 8 ounces. Digest with occasional agitation, for fourteen days, in a warm place, then set aside to fine, and pour off the clear.

GOLD SIZE. — Yellow ochre, 1 part; varnish, 2 parts; linseed oil, 3 parts; turpentine, 4 parts; boiled oil, 5 parts; mix. The ochre must be reduced to the finest powder, and ground with a little of the oil, before mixing.

EXPLOSION OF STOVES HEATED BY NAPHTHA. — The *Gas-light Journal* says: "We hear of numerous instances of the explosion of stoves in which the light oils of petroleum were employed as the source of heat. Several persons have been burned to death, and a large amount of property has been destroyed by fire. Notwithstanding these fatal accidents the sale of the dangerous oil goes on, and the patent lamps and stoves are sent all over the country. We must again utter a note of warning, and remind our readers that it would be quite as wise to try to burn gunpowder in a stove, as it is to use naphtha for heating purposes. By means of a very ingenious apparatus, and the practice of great skill, Bunsen burned gunpowder and analyzed it; that is no reason why everybody else should repeat the experiment. It is equally possible to burn naphtha and explosive oils in lamps and stoves, but as the precautions to be observed are numerous and difficult of execution, no one but the best trained chemist ought to venture to use these liquids for heat or light. The sale of such articles to the public ought to be prohibited by the most stringent laws."

TO CLEAN LAMP CHIMNEYS. — When you wish to clean a lamp chimney, hold a linen cloth against one end of the chimney and place the other end in your mouth; breathe in it until it is covered inside with moisture, push the cloth into the chimney with a smooth slender stick, and rub it around until the moisture is absorbed; repeat the process and breathe over the outer surface also; rub this with a cloth until dry, and you have a clean, bright chimney. Soft newspaper will take the place of a linen cloth. Do not use cotton cloth on any glassware.

ALL IS NOT GOLD THAT GLITTERS. — If the following is not true, any practical chemist will bear testimony that it is at least *ben trovato*. A verdant-looking Vermonter appeared at the office of a chemist with a large bundle in a yellow bandanna, and opening it, exclaimed: "There, doctor, look at that." "Well," said the doctor, "I see it." "What do you call that, doctor?" "I call it iron pyrites." "What, isn't that gold?" "No," said the doctor, and putting some over the fire, it evaporated up the chimney. "Well," said the poor fellow, with a woe-begone look, "there's a widder woman up in our town has a whole hill of that, and I've been and married her!"

Agriculture.

HOW GYPSUM ACTS UPON SOILS.

A VERY interesting discussion followed the delivery of the address we gave at the Fall River meeting of the Massachusetts State Board of Agriculture last autumn, at the close of which we remarked: "There are certain points in husbandry which ought to be assumed as *settled*, and when a matter is settled it ought not to be continually opened and brought back again into the field of controversy. This is too much the case with matters connected with our agricultural operations. In this industry there are certainly some established principles or facts which should serve to guide us, and we must seize hold of them and hold on to them, and add as many more as we can. In this way agriculture will be brought to as near a scientific basis as is possible."

President Chadbourne, of Williams College, in replying to these observations, assented to them in general, but he thought that "with all our science and all the general rules we can lay down, there are still very many things which we do not understand in farming." He instanced the fact that we did not yet know why gypsum or plaster would produce remarkable effects on one piece of land and not on another. He stated that he had applied it to his own fields with no good results, and he could not understand the cause of failure.

The exact way in which gypsum produces its fertilizing effects is not well understood, although it is understood that the chemical changes or transformations which occur when it is brought in contact with soils are not of a uniform or fixed character. Upon the conditions which exist, as regards the presence of vegetable matter and moisture, depend the changes that take place. We have proved by actual experiment that gypsum is capable of absorbing ammonia from the air and also from decomposing vegetable matter, being thereby changed into hydrosulphide of ammonium; and this again may be changed into carbonate of ammonia by absorption of carbonic acid from the air. These changes take place when gypsum is brought in contact with moisture and vegetable matter. Whatever other decompositions may take place under different circumstances, this must be regarded as the most important, as from it plants are supplied with food of the highest value. From these ascertained facts we should infer that plaster must prove highly serviceable to moist, mossy hills, and also to meadows not too wet, and this has proved correct so far as our observations extend. Often we have found that the *north* side of a hill will be greatly benefited by plaster, while upon the southern exposure it has no perceptible effect. This is due to the fact that the northern slope is cooler, or oftener in shade, and has more moisture, and a larger amount of partially decayed vegetation, to aid in the promotion of those chemical changes to which we have alluded.

It is certain that it does not matter so much what may be the nature of the soil to which we apply plaster, as external agencies are principally concerned in fitting it for plant food.

While the question as to how plaster acts in all cases as a fertilizer cannot be regarded as fixedly *settled*, yet we have certain facts to guide us in its application which are of the highest importance. With what we know, it would be absurd for a farmer to apply the agent to a dry silicious plain, or to a hot, impoverished hill; and also it would be unwise to sow it upon a meadow which is covered by water six months in the year. It must also be observed that the season has much to do with the effects of plaster. During the past three or four seasons of extreme drought, its application has notably failed upon almost all fields, but as soon as we have continued moisture through the summer months, it will manifest its influence upon vegetation.

Plaster may be applied with confidence to pastures and fields which are strong enough and moist enough to sustain a good growth of deciduous trees. Pine lands are not usually benefited by it. A hillside where moss will grow so as to crowd out good grasses is usually promptly benefited by plaster, and the white clover comes in at once. These suggestions we think may serve as an imperfect guide in applying a cheap and important fertilizing agent to our fields, and also serve to show that we are not entirely in the dark respecting one of the most obscure problems connected with husbandry.

INTERESTING FARM EXPERIMENTS.

WE have been greatly interested in the report of some experiments made by Mr. C. D. Hunter, chemist, at the farm of our friend Wm. Lawson, Esq., Cumberland, England. This is the well known "Blennerhasset" farm, which, during the past five years, has been largely devoted to experimental purposes under the direction of Mr. Hunter. His experiments have been conducted with much care, and extend over a wide field. On seeds, nitrate of soda applied alone, in 1868–1871, gave, as the average of the four years, 54 stones of hay for every cwt. of manure applied; when used along with superphosphate and muriate of potash, it gave 58 stones of hay per cwt. Sulphate of ammonia used alone gave 50 stones (a stone is 14 pounds) of hay per cwt., and in conjunction with mineral manure $48\frac{1}{2}$ stones. Peruvian guano, again, used alone for three years, gave about eight stones less than sulphate of ammonia for the same period, or equal to 42 stones; and in mixture it gave equal to 30 stones. Nitrate of soda, it will be seen, proved the best nitrogenous manure for hay, and also went furthest when used along with a mineral manure. On a clay soil only one experiment was tried last season. The land was in a very poor condition; the unmanured crop weighing only about 10 cwt. per acre. On this poor clay sulphate of ammonia proved superior, giving when applied alone a return of 65 stones per cwt. of manure, and with superphosphate and muriate of potash 95 stones. Nitrate of soda gave alone 39 stones of hay, and in mixture 66 per cwt. The experiments on oats are fairly trustworthy, but having been tried on but one soil and under the unusual conditions of three years on the same land, they must not be regarded as entirely applicable to ordinary farming. From a want of reliable no-manure and mineral-manure plots for comparison the figures given may be, as a whole, a little too high or too low; but the comparisons between the three manures are quite exact. Applied alone, sulphate of ammonia proved superior for oats; and, taking its return per cwt. of ma-

nure at 12 stones of corn, Peruvian guano gave 11, and nitrate of soda nearly seven stones. Applied in conjunction with mineral manure, nitrate of soda proved superior; and, taking its return per cwt. at 20 stones, sulphate of ammonia gave 18, and Peruvian guano 17 stones. It is rather curious to find nitrate of soda last when used alone, and first when in mixture. One point seems, however, pretty well established, namely, that sulphate of ammonia and Peruvian guano proved of nearly equal value in both cases. The guano used was the Chincha Island of best quality, the supplies of which are now exhausted; but any guanos containing over six or eight per cent. of ammonia will prove a good corn manure. Barley was also experimented with for three years upon the same soil: the same remark applies to this as to oats, namely, that the weight, as a whole, may be a little too high or otherwise, but that the comparisons are just enough. Nitrate of soda here takes a decided lead all through, and, taking its return per cwt. of manure at 20 stones of corn, Peruvian guano gives only nine stones. Sulphate of ammonia was not tried alone, but in mixture proved superior to Peruvian guano: thus, nitrate of soda used with mineral manure gave about 14 stones of corn, sulphate of ammonia 11½, and Peruvian guano about seven stones per cwt. of nitrogenous manure. This shows nitrate of soda twice as valuable for barley as Peruvian guano, and slightly superior to sulphate of ammonia. On potatoes he experimented very largely, and has, from over 400 trials, a number of very valuable facts bearing upon the seed cultivation and manuring for this crop. An average of six very reliable plots gives 161 stones of potatoes as the produce per cwt. of sulphate of ammonia, used in conjunction with superphosphate and nitrate of potash; Peruvian guano, in the three years' trial against this, gave equal to 99 stones, and nitrate of soda 39 stones. Some other experiments place nitrate of soda still lower, and two trials with Peruvian guano used alone, give 84 stones per cwt. of manure, but these are not strictly comparable with the others, being on different soil each year.

From the foregoing experiments on the action of nitrogenous manures, it is evident that the value of a manure is affected by the source of its nitrogen as well as by its amount, and that a statement of the raw materials used in making the manure is essential to a correct estimate of its value. An analysis protects the farmer from adulteration, and a composition may protect him from misapplication: thus, if these results hold good on the generality of light soils in Cumberland, it is evident that a potato manure containing nitrate of soda is much inferior to one containing sulphate of ammonia, though both may analyze the same percentage of nitrogen; four per cent. of this being supplied by either 16 per cent. of sulphate of ammonia or by 26 of nitrate of soda. Again, suppose two grass manures, and let one contain 30 per cent. of nitrate of soda; this would make it analyze about four and two thirds per cent. of nitrogen, and it would be better value for light land than one analyzing five per cent. of nitrogen furnished by 20 per cent. of sulphate of ammonia, though the latter — if the one experiment on clay land proves of general application — would be of more value again for stiff soils.

POTASH IN CORN COBS.

Several months ago we published the results of analysis of corn cobs raised at Lakeside farm, with the view of showing their nutritive value. The ash constituent of the cobs was not alluded to, although some interesting facts may be stated regarding it. The corn cob is very rich in potash, and it has been suggested that our supplies of the alkali might be greatly increased, if all the cobs produced in the country were collected, burned, and the ash lixiviated to procure the potash. The average amount found in the ash of cobs is about 7½ pounds of the carbonate in the hundred, which is twice as much as is found in the ash of the willow, the richest of all woods in this salt. If it were practicable to procure and remove the potash from all the cobs grown in the United States, it would indeed constitute a mountain of the valuable alkali.

The corn crop of the United States, for 1870, was 1,094,000,000 bushels, of which amount

Illinois yielded	201,378,000	bushels.
Indiana "	113,150,000	"
Missouri "	94,990,000	"
Iowa "	93,415,000	"
Making a total of	502,933,000	bushels.

in four States alone.

The corn crop of the whole country, for 1871, was 1,100,000,000 bushels, which, at 14 pounds cobs to the bushel, will yield 15,400,000,000 pounds, or 7,700,000 tons of cobs, containing an average of three fourths per cent. pure carbonate of potassa. We have the enormous quantity of 115,500,000 pounds of that valuable alkali lost to commerce annually, which, if thrown into trade, would add very largely to the general resources of the country.

A VERY GOOD COMPOST.

A very good fertilizing compound is manufactured by using the following substances according to the directions given. The mixture has been called "Liebig's great Fertilizer," as it is stated that it originated with him. This is doubtful, but it is a very judicious and sensible combination nevertheless, easy to prepare, and cheap. It will prove serviceable for corn, wheat, and the other cereal grains, and also for grapes.

This amount will do well, applied to one or two acres, and it will cost not far from $16: —

1. Dry peat, twenty bushels.
2. Unleached ashes, three bushels.
3. Fine bone dust, three bushels.
4. Calcined plaster, three bushels.
5. Nitrate of soda, forty pounds.
6. Sulphate of ammonia, thirty-three pounds.
7. Sulphate of soda, forty pounds.

Mix numbers one, two, and three together; then mix numbers five, six, and seven in five buckets of water. When dissolved, add the liquid to the first, second, and third articles. When mixed, add fourth article.

WHEAT LANDS IN ENGLAND AND RUSSIA.

In the eleventh century the average production in wheat per acre, in England, was stated to have been only 6 bushels. To-day the average in England is 27 bushels. This progress is due to our having more knowledge about agriculture. We know more about soils, about implements, manures, etc., than in the olden time. One reason for the advancement we see, is the improvement in our agricultural implements. Thus the plough has been wonderfully improved over what it was in Europe in the Middle Ages.

It is knowledge that men want. The difference between England of five centuries ago and of to-day, is a difference in knowledge. Knowledge has enabled England to multiply many times the products of agricultural operations, and also to multiply the number of human beings she can support. Much of this knowledge is traditional, but it is also preserved in the records — the writings of those who have studied those subjects.

In England to-day there are no exhausted lands; they are not allowed to deteriorate. What is taken off is supplied again, and this is the only true economy. We cannot take away from our land, and not restore, without injuring the soil.

Russia, unlike England, seems to be following in the footsteps of this country in the neglect of her wheat lands, and, as a consequence, complaints are already being made that the average yield of her grain crops is constantly growing less. There, as the *Scientific Press* says is the case in California, valuable farmyard manure is, in many places, being conducted to the nearest waste ground or stream as a nuisance. Still, Russia is buying largely of reaping and threshing machines, as well as other agricultural machinery.

SEEDS AND CUTTINGS.

Small Farms at the South. — The *Journal of the Farm* remarks, that at length the popular mind of the South appears to be awakened to the fact, that small farms, instead of unwieldy plantations, are the great need of that section. The worn-out condition of the majority of these overgrown farms is the strongest argument against them, and in fact the only one that need be advanced. If the owners of these large tracts would sell off one half, and devote the proceeds to the improvement of the remainder, the beneficial results would be seen in a very few years. This is especially applicable to Virginia, where the spirit of agricultural improvement is manifesting itself in a most gratifying manner, and it is in this State that the disposition to cultivate fewer acres, and cultivate them better, is beginning to be largely developed. There are, therefore, or are likely to be, large quantities of excellent land in the market for sale, which can be purchased at very moderate figures, and which should attract the attention of those who are seeking investments of this character. With smaller farms, and an increased population in consequence, there is no reason why the Old Dominion should not again assume her rightful position in an agricultural sense.

Dairy Products. — Statistics show that the value of the annual products of milk is nearly equal to the value of imports for the year ending June 30, 1871. Milk, consumed as food, at three cents a quart, is worth annually $275,000,000; butter, $195,000,000; cheese, $29,000,000; condensed milk, and whey and buttermilk, used in raising pork, $10,000,000; making a total of $509,000,000. The imports of all kinds are worth $520,000,000. So that from American cows' udders is squeezed every twelve months an equivalent to one fifth of the national debt. All the greenbacks and the postal currency in the country could buy only four fifths of it.

Bass-wood for Drains. — The *American Rural Home* says that Mr. Root, a leading farmer in western New York, finds bass-wood (ordinarily one of the most perishable of all kinds of wood) is one of the best sorts of timber for underground logs or pipes for conveying water over farms. He claims that bass-wood soaks full of water, and is constantly saturated — a condition well known to favor durability. He has three hundred rods of water pipe made of bass-wood saplings, now laid nine years, and perfectly sound.

Boston Journal of Chemistry.

Jas. R. Nichols, M. D., *Editor.*
Wm. J. Rolfe, A. M., *Associate Editor.*

BOSTON, JUNE 1, 1872.

THE JOURNAL.

This number of the Journal closes Volume VI., and we take the opportunity of thanking our numerous friends and patrons for their most generous support. During a period of six years the Boston Journal of Chemistry has continued its monthly visits to thousands of happy homes, and its readers are scattered from the wild regions of Alaska to the verdant glades of Florida. In every State and Territory of the United States, and in many of the countries of Europe, and to Australia, South America, Sandwich Islands, etc., the Journal has found its way during the past six years; and this has been accomplished with but little effort on our part. Its mission is to supply valuable scientific facts and information to all intelligent readers, to improve and elevate the masses, and render life happier. We have abundant evidence that in this work it has been successful, and so, although wearied with other cares and responsibilities, which in themselves would seem a sufficient burden, we shall continue to labor for the benefit of our readers, so far as strength will permit.

PATRONS IN ARREARS.

We have the names of a few patrons upon our books who have not paid for the present volume of the Journal, and also there are a number who are in arrears for two years. We have placed in the papers directed to them bills, to which we trust they will give prompt attention, as it is important that our accounts should be adjusted at once.

ACROSS THE BIG FERRY.

We design to spend a few months in Europe the present season, leaving in the *Siberia*, June 4th. The many exacting cares and responsibilities which have crowded upon us during the past ten years have so far exhausted our energies that relaxation is necessary. We shall leave the Journal in good hands, and hope upon our return to have secured a store of strength and information which will enable us to make the paper more attractive and useful.

WHOLESALE POISONING FROM THE USE OF A "PATENT SANITARY WATER PIPE."

It appears from the following statement published by the Board of Health of the city of Sacramento, Cal., that the citizens have been suffering severely from the poisonous effects of a new "sanitary composite" water pipe used for conducting water into dwellings in that city: —

In the discharge of their duties, both officially and professionally, the Board of Health deem it incumbent on them to publish the following statement: —

No less than seventeen cases of illness, presenting all the most unequivocal signs and symptoms of lead-poisoning, have come to our knowledge within the last month in this city. Most of these cases have partaken of the characteristics of slow, chronic poisoning, clearly diagnosticated in lead, from ordinary colic, by a blue line on the dental edge of the gums, whilst some of them have been suffering terribly for several months, previously to our becoming cognizant of the fact, with intense muscular pains and loss of power, more or less approximating paralysis — all of them occupying residences supplied with water from pipes made of a patent composite metal, advertised and known as a "sanitary water pipe." It is here proper to remark, that the earlier symptoms of this affection are so obscure in their origin, and simulate so closely other diseases of the stomach and bowels, that physicians are frequently in doubt as to the true nature of the cause of suffering until sufficient time has elapsed to obtain positive signs of metallic poisoning — lead, which is the most easily dissolved metal in water, and at the same time most poisonous in minute quantities, being a cumulative poison. In no single instance referred to above had the patient not been subjected to the action of the water served from the aforesaid composite metal pipe; and not a solitary case has been heard of, in the whole city, of symptoms coördinate with those described, where the old lead pipe had been in use.

As soon as our suspicions became aroused as to the cause of suffering, directions were forthwith issued to discontinue the use of the water supplied by the composite pipe, when a steady and happy alleviation of the most urgently distressing symptoms — such as the dragging and twisting pain of the bowels, the obstinate constipation, and, in the worst cases, vomiting — ensued. Under these circumstances a meeting of the Board of Health was called, and the whole matter confided to the hands of our secretary, with a request that he would make such an investigation as the emergency rendered necessary, and report the result to the board. We now beg leave to call attention to the following very satisfactory report which has been adopted by us, and which, it will be observed, not only confirms the correctness of the suspicions that were entertained, but also positively establishes the fact that the composite pipe in question is not only detrimental to the health of our citizens, but is also dangerous to life, and should under no conditions be employed in distributing the waters, at least of the Sacramento River.

(Signed) I. E. Oatman, M. D., President.
F. W. Hatch, M. D.
W. R. Cluness, M. D.
G. L. Simmons, M. D.
Thos. M. Logan, M. D., Secretary.

The water passing through these pipes was analyzed by J. F. Rudolf, chemist, and found to contain both lead and arsenic in notable quantities. It does not appear from the reports of the chemists, secretary, or Board of Health, that any investigation has been made into the nature of the "composite sanitary pipe," and so we are left in the dark regarding a most important point. It may be the highly "sanitary" galvanized iron pipe, or the "brass pipe," or (which is more probable) it may be a "new invention" of some genius whose ignorance or stupidity has led to the poisoning of a whole community.

It is very strange indeed that intelligent people are so easily duped and deceived. It would not seem possible, when contemplating the extraordinary advantages which are afforded for acquiring knowledge, that an irresponsible adventurer could appear in any city or town, and induce the inhabitants to use a service pipe for water conduction, constructed of different metals of unknown character. It seems unaccountable that a single foot of the filthy, dangerous, zinc-covered pipes, could have been used for water conduction in any part of New England; and yet, in the city of Cambridge, which has within its precincts the most famous university in the country, it has been employed to a considerable extent. It is true cultivated people are not all medical men or chemists, but it is reasonable to infer that education of any kind must lead to the exercise of proper caution upon all matters which involve sanitary results. An education which does not enable persons to discriminate between the preposterous pretences of a quack, and the reasonable and careful statements of a scientific man, is certainly very defective. In these days, devices of every kind and for all possible uses are urged upon the attention of the community, and it is manifestly the part of wisdom to hesitate to adopt anything, unless its merits have been fairly investigated by those who are competent to judge and entitled to full confidence.

FALLEN GREATNESS.

The recent return of the birthday of the Prince Imperial of France brought vividly to mind the circumstances under which the young man was ushered into existence. We were in Paris sixteen years ago, upon the 16th of March, and were personally cognizant of what transpired in the city upon that auspicious day. In a splendid apartment of the Palace of the Tuileries the child was born, while the courts and waiting rooms of the Imperial residence were crowded with the most distinguished generals and statesmen of the empire. Outside, the booming of cannon was heard, and the dingy barracks of the *Invalides* were enveloped in the smoke of gunpowder. All over France the day was spent in rejoicing, more or less sincere, that a son and heir to the throne of the empire was born. Upon the occasion, it was hoped that the representatives of the great Powers, who were assembled in Paris to settle the conditions of peace, would reach a fixed result and proclaim it to the world. But in this the Emperor was disappointed, as the final documents were not signed until about two weeks after the birth of the Prince. The preparations for the birth were interesting and curious. For more than a fortnight the cannon upon the grounds at the *Hôpital des Invalides* had been kept loaded, and the veteran gunners, with lighted match-rope, were marching to and fro behind them, ready at the first signal from the Palace of the Tuileries to ignite the charges and proclaim to the people of the city not only the fact of the birth, but the sex of the child. No preparations or arrangements were made for a Princess. We crowded our way through the thronged street to the millinery establishment where was placed on exhibition the clothing for the expected child, and the vast array of little socks, sacks, dresses, etc., were of the most costly nature, and exquisitely wrought of lace and satin. Hearing the guns booming early in the morning of the 16th of March, 1856, we rushed out of our chambers to learn the news, and were informed that the Emperor's star was still in the ascendant; "a *garçon*" had been added to his household.

Such were some of the circumstances under which the youth was born who recently celebrated his sixteenth birthday in exile, at Camden House, Chiselhurst, England. He came a fugitive to England a few days after the Revolution of September 4, 1870, and, after a brief sojourn at Hastings, took up his residence with the Empress, where they were rejoined by the

Emperor only after the conclusion of peace and his release from Wilhelmshöhe. At the date of his arrival in England, the health of the young Prince, which had never been very robust, was rendered still more precarious in consequence of the disastrous campaign of 1870, and the repose and quiet of his new place of residence, coupled with the bracing English atmosphere, soon effected in his physical appearance, as well as in all other essential respects, a change truly marvellous. From a slight and somewhat effeminate lad, he rapidly grew into a strong, healthy, well conditioned youth, fond of outdoor sports and exercises, an excellent horseman, and in all respects as ruddy and hardy as the majority of English boys of his age. There is in his entire bearing a manly simplicity most engaging, and immediately noticed by all who come in contact with the Prince.

A considerable number of ladies and gentlemen went from London to present their respects to the Emperor and Empress upon their son's birthday anniversary, and they received a cordial greeting from the distinguished exiles.

Shortly after 11 o'clock their Majesties and the Prince Imperial, with their household suite, and all the ladies and gentlemen who had arrived in the morning from London, set out on foot from Camden House to attend Divine service at the Roman Catholic chapel at Chiselhurst, distant about a quarter of a mile from Camden House. Their Majesties crossed Chiselhurst common, respectfully greeted by large numbers of persons assembled to see them, and upon entering the chapel took their places in chairs provided for them, immediately in front of the altar. A high mass was then chanted, several priests taking part in the impressive ceremonies, which terminated with the *Te Deum*, the performance of the entire mass occupying nearly an hour and a half. The pretty little chapel was charmingly decorated with flowers, and was, of course, crowded in every part. At the conclusion of Divine service the Imperial family returned on foot to their residence, accompanied by their friends, and again saluted with every demonstration of sympathy by a throng much more numerous than had previously assembled.

A simple reception was held immediately afterwards by their Majesties and the young Prince, on the spacious lawn in front of the principal façade of Camden House, each of those present receiving a kindly pressure of the hand, and a few courteous words from the Imperial family. The Empress, who appears to have in some degree recovered from the terrible mental trials she has recently undergone, manifested, by her winning vivacity and gracious manner, her lively appreciation of the sentiment which had brought together the ladies and gentlemen assembled around her; and the Prince Imperial made the best possible impression upon all present by his manly, unassuming attitude, and the beaming smile with which he received the felicitations of his friends.

CARBONIC ACID.

It is often stated as one of the wonders of plant life, that plants are able to do what the chemist has failed to do, that is, to decompose carbonic acid.

While it is extremely difficult to decompose carbonic acid, completely separating it into carbon and oxygen, nevertheless it is quite easy to partially decompose it. If we pass a stream of the gas through a tube containing red-hot coals, the coals are burnt at the expense of half the oxygen contained in the carbonic acid, and carbonic oxide is the result. Hydrogen, iron, and zinc act similarly towards it, abstracting half its oxygen.

Potassium burns in it with a red light, producing carbon and carbonate of potassium. This experiment may very readily be shown to a class by taking a tube about three fourths of an inch in diameter and ten inches long, bent at right angles near the upper end, which is sealed in the lamp. A piece of potassium about the size of a pea is introduced into the tube, which has been previously filled with dry carbonic acid over mercury, as all aqueous vapors must be avoided; by inverting the tube the potassium is lodged in the upper end of the bent portion. If it is now heated by a lamp, the first action is to expel a portion of the carbonic acid from the tube; as soon however as the potassium approaches a red heat, it takes fire and burns vividly, completely absorbing the carbonic acid, if it is present in sufficient quantity. Sodium also decomposes carbonic acid, but without taking fire. In the presence of the alkalies at red heat, phosphorus and boron have the same action.

FAIRMOUNT WATER.

The good people of Philadelphia are content to use very objectionable water, if the specimen sent to us for analysis by a gentleman of that city fairly represents the fluid flowing from the Fairmount water-works. The specimen sent to us contained in each U. S. gallon (231 cubic inches): —

Inorganic matter	4.67 grains.
Organic matter	2.62 "
Total solid contents . . .	7.29 "

A large amount of iron was present in the water, which undoubtedly came from the iron pipes through which it passed. The organic matter was in a state of putrefactive change, and communicated to the water a very offensive odor. This matter largely comes from sewage, and must render the water to a certain extent injurious to health. The water distributed through the Fairmount works has undergone serious deterioration since it was examined by Prof. E. N. Horsford several years ago. His results at that time gave, in each U. S. gallon, —

Of inorganic matter . . .	2.30 grains.
Organic matter	1.20 "
Total solid contents . . .	3.50 "

CANNED FRUITS.

The impression prevails among those who use the fruits freely which are put up in tin cans, that they are injured thereby, and this impression is in many cases correct. We have long contended that all preserved fruits and vegetables should be stored in glass, and that no metal of any kind should be brought in contact with them. All fruits contain more or less of vegetable acids, and others that are highly corrosive are often formed by fermentation, and the metallic vessels are considerably acted upon. Tin cans are held together by solder, an alloy into which lead enters largely. This metal is easily corroded by vegetable acids, and poisonous salts are formed. Undoubtedly many persons are greatly injured by eating tomatoes, peaches, etc., which have been placed in tin cans, and we advise all our friends who contemplate putting up fruits the present summer to use only glass jars for the purpose.

A NEW WORK ON ELEMENTARY CHEMISTRY.

Messrs. Ivison, Blakeman, & Phinney, of New York, publish Prof. Nichols's abridgment of Eliot and Storer's "Manual of Elementary Chemistry." The original work has been greatly condensed, but we are sorry to find that its diffuse and defective character is in a measure retained. Several chapters on the components of carbon have been added, which are of considerable importance. As a rule, the experiments are too minutely described, and nothing is left for the teacher or pupil but the mere manipulation, every step of which is given in detail. There is also found on several pages a repetition of statement, using language slightly modified, which would have been better omitted. For instance, on page 220, it is stated that "Potassium carbonate is a *hygroscopic* salt, and very soluble. When exposed to damp air, it *deliquesces* or becomes *moist*." On page 56, alluding to chlorine: "It combines with hydrogen with explosive violence, when a mixture of the two gases is heated, or even exposed to sunlight;" then immediately follows: "In direct sunlight the union is so instantaneous as to be attended with explosion." There are also several errors of statement which should be corrected in future editions. On page 246 it is stated that "Calcic phosphate is a valuable manure, no matter from what source it is obtained, if it is reduced to a fine powder." This is wrong. The mineral phosphates differ from the bone phosphates. The mineral, being found mostly in the form of apatite, is *entirely inert in powder*, and in order to exert fertilizing influence, must be acted upon by acids.

We could point out a considerable number of serious errors and defects in the work; but we do not wish to appear captious, or unreasonably inclined to fault-finding. Prof. Nichols deserves credit for the pains he has taken to abridge the work of Storer and Eliot, and there is much in the arrangement to commend; but an elementary text-book upon any department of science should be compiled with the greatest care, for if we start our youth wrong, it is almost impossible to set them right in after life.

[Communicated to Boston Journal of Chemistry.]

PROFESSOR DANIEL KIRKWOOD.

I have noticed in your excellent journal several references to Professor Kirkwood, and to what he has done, with extracts from his publications. It occurred to me that your readers might be interested in a brief sketch of the man and his labors. Professor Kirkwood is one of our most eminent scientific men, and a scholar of whom America may well be proud. It is quite certain that no other living man approximates so nearly to the celebrated John Kepler in certain mental characteristics, habits of study, and methods of "handing down" the laws of Nature in the physical world, and it is doubtful whether any other has lived. His mind seems to be stored with fruitful hypotheses, which hard and consecutive thought, intuitive perception of what must be true in Nature, and long and tedious calculations, in very

many instances, have proved to be truthful representations of Nature's laws.

The Student and Intellectual Observer, a scientific periodical published in London (Groombridge and Sons, Paternoster Row), has an article of twelve pages in the number for August, 1869, by the distinguished astronomer, Richard A. Proctor, F. R. A. S., devoted to the scientific researches of Prof. Kirkwood. The writer of the article is a man capable of appreciating the value of Prof. Kirkwood's labors, and he has spoken of them as they deserve. I shall here give the concluding paragraphs: —

"It would not be easy to exaggerate the importance of Prof. Kirkwood's researches. Founded as they are, not on speculative fancies, but on the well-established laws of planetary motion, they are worthy of the closest attention. I believe they will inaugurate new and important processes of thought, by means of which the noble but hitherto intractable problems connected with the formation of the solar system may be found capable of solution."

Daniel Kirkwood was born in Hartford County, Maryland, September 27, 1814, so that he is now in his fifty-eighth year. His advantages for education when a boy were, as is too often the case, *dis*advantages. When he was sixteen years of age he went to York County, Pennsylvania, and attended during the winter a school taught by his cousin, Samuel J. Kirkwood (who has since been Governor of Iowa), then a boy near the same age. His principal studies were arithmetic and geography. When he was nineteen years of age he also began to teach. But I have no space for details. I can only say that, his mind once awakened, the acquisition of knowedge became both a pleasure and a necessity, and in course of time he found his mind well stored with the elementary and the higher mathematics, and with the facts and principles of science. Two colleges have conferred on him the honorary degree of A. M., and one the degree of LL. D. It is well known that he is the discoverer of what is called "Kirkwood's Analogy," a law which binds together the masses and rotations of the planets of our system. This discovery was made known about the year 1849. Except about a year, while he was in Washington and Jefferson College, Pennsylvania, he has been in the Indiana State University, as professor of mathematics, since 1856. In 1867 he published a valuable work on "Meteoric Astronomy." The reader will find a very interesting article of his on the Nebular Hypothesis, in the *Monthly Notices of the R. A. S.*, vol. xxix. pp. 96–102. DAVID TROWBRIDGE.

EDITORIAL NOTES.

A SATCHEL GUIDE FOR THE VACATION TOURIST IN EUROPE. — This is the title of a little book just published by Messrs. Hurd and Houghton, which seems to us to be precisely what is wanted for the large and growing class of travellers who are finding out that a summer vacation abroad costs less than a shorter one spent at the seaside or mountain resorts in our own country. For those who have *not* yet found this out, the book is worth buying for the "Introductory Hints" alone, which show more fully and more clearly than any similar work within our knowledge how cheap a foreign tour may be made without any sacrifice of comfort or enjoyment.

There are, we believe, only three European guide-books published in the United States. Two of these are large works, covering all the countries of Europe, and excellent for those who can spend a year or more on the foreign tour, and who are as well off in point of "lucre" as of leisure. The other is professedly a "short trip" guide, but errs in covering too much ground, so that it is little else than an "abridged" *general* guide. It is also marred by many inaccuracies, especially such as arise from an ignorance of the French and German languages. The writer of a guide-book ought, it would seem, to have at least a smattering of those foreign tongues, if only to save him from saying that Ehrenbreitstein means "the *bright* stone of honor," calling the Conservatoire des Arts et Métiers at Paris "the Conservatory of Arts and *Measures*," and the like. But the chief defect in all these books is that they do not give the inexperienced tourist the information that he most needs, if he would make the most of his time and his money. They lay down a lot of separate routes, but do not tell him how to *combine* them so as to save unnecessary travel, which wastes both time and money, to say nothing of patience and comfort. Neither do they tell him how to travel economically. They give a little general advice on that point — so general that it is practically worthless — but nothing definite and precise. The only hotels they commend, or even mention by name, are the more expensive ones, while the book before us makes it a point to enumerate the cheaper ones also. The author has evidently made a special study of the wants of all classes of tourists, and not merely of those who travel "regardless of expense." We have no doubt that among the readers of the JOURNAL there are hundreds of hard-worked men of moderate incomes — physicians, clergymen, teachers, students, and others — who would at once make up their minds to indulge in a vacation in Europe, after reading this "Satchel Guide," since they would see (what they may never have suspected) that it is a luxury by no means beyond their reach.

CARELESSNESS IN SANITARY ADVICE. — A popular journal, in an article on disinfectants, gives directions for making chlorine on a scale that requires ten ounces of salt, and six ounces of strong sulphuric acid, and puts the apparatus to work for ten or twelve hours in a room tightly closed; but adds no hint in regard to the possible *bleaching* action of the chlorine, though he refers to using the agent even in a "parlor." This is an illustration of the mistake too often made by those who write on scientific matters for unscientific readers. They forget that the precautions in the use of dangerous chemical agents which are perfectly familiar to themselves are wholly unknown to those whom they are addressing. No one should write on such topics for "the million," unless he knows how to put himself in the position of his readers, and to look at things from that "stand-point."

AN ASTRONOMER'S POODLE. — We see in the *Pall Mall Gazette* an amusing account of a recent scene in an English court-room. The estate of the late Sir James South is in process of administration, and it appears that, among other bequests, he gave one of his female servants an annuity of £30 a year during the life of a favorite dog named Tiger, of which she was to take care. The Chief Clerk certified that he was unable to say whether the annuity was still payable, having no means of ascertaining whether the dog was living or not, and the executor thereupon called for the production of the animal for the purpose of satisfying the court whether the estate was still chargeable with the annuity or not. Mr. Little, Q. C., and Mr. Martin, who appeared for the dog, having consented to his being produced, "a matronly looking female was ushered into the solicitors' well, and from the folds of an ample cloak appeared the features of a fat and panting little lap-dog, that surveyed the scene with glassy eyes, and resented the intrusion upon his privacy by a few feeble barks as he was carried from the court." No sooner had he retired than his counsel rose and demanded that £1,000 Consols should be set apart to secure his annuity. The Vice-Chancellor, however, held that the rule of the court which applied to human beings did not extend to dogs, and said that the executor's personal undertaking for the rest of the dog's life would be sufficient. "This denial of the usual security granted in such cases seems certainly a little hard upon the dog, whose position in other respects appears to be precisely identical, or, as lawyers say, 'on all fours,' with that of a human legatee. He has as yet, however, given no notice of appeal."

GREENBACKS AND GRAVITY. — Paper money is light stuff compared with the substantial coin that it represents, but in the aggregate it is heavy enough. The Secretary of the Treasury reports the following statistics on this subject:

	Pounds.	Cost.
National bank notes . . .	100,858	$78,669.24
Greenbacks	206,639	175,344.45
Fractional currency . . .	319,176	243,406.94
Bonds	110,873	91,387.63
Internal revenue stamps	78,062	36,689.14
Total	812,608	$625,494.40

But this is not all. There is a reserve of paper to be manufactured into greenbacks, fractional currency, bonds, and revenue stamps, amounting to 257,183 pounds, costing $204,812.36; so that the grand total of paper used or to be used in our paper money, is 1,069,791 pounds, costing $830,306.76. It will give the reader some idea of the amazing bulk of our paper money, bonds, etc., to know that 535 tons of paper are required for their production.

FIRESIDE SCIENCE. — In the course of a very commendatory notice of this book, the *Scientific Press* of San Francisco remarks: —

"It is one of the most encouraging signs of the times that there is a growing demand and taste for really valuable and instructive reading, and he who can render science attractive to the busy working men and women of our country is better than he who taketh a city. The demand of the day is that science should be brought down to the comprehension of the popular mind, and made to minister to the needs and pleasures of the people. To do this it must be divorced from the trammels of technology, and made plain and attractive to the common mind. There is no difficulty in doing this; and he who most successfully leads in this new path of literature is engaged in a noble and most important work for the elevation of the masses. 'Fireside Science' should find a place in every home in the land."

ATOMS.

THE question has been raised whether the druggist was justified in selling vermifuge to the small boy who asked for "a bottle of subterfuge." — It was Biot, we believe, who said: "In doubtful questions, the ignorant believe, the half-learned decide and the man of science examines." — It is stated that iron by hydrogen often contains impurities, such as oxides and carbonates, and even cyanide of potassium; and it would be well to test it for the last, since it is so dangerous. — Professor Blot, of culinary renown, always urged that flour should be kept in bags, not in barrels; and we see that Herr Poleck, of Silesia, has recently shown that there is good ground for the advice, as the flour kept long in barrels undergoes an incipient decomposition, by which the gluten is partially changed into a soluble substance. — An English physician has written a book to prove that "consumption *always* originates from the breathing of pre-breathed air;" and, though that may be putting it rather strongly, there can be no doubt that rebreathed air is one of the most fruitful sources of this and many other forms of disease. — Dr. Roux says that the French, by daily using copper cooking utensils, take copper enough into the system to render its detection in the blood an easy matter. — A plan for uniting the Black and Caspian Seas by a canal, at an expense of fifty millions of dollars, is engaging the attention of the Russian government. — To illustrate the extent of the match-making in Marseilles (France) it is stated that a single firm employs 600 hands, and consumes annually for

the production of matches 2.5 tons of phosphorus; 7 tons of chlorate of potassa; 1.5 tons of coloring matter; 8 tons of red-lead; 16 tons of refined sulphur; 50 tons of stearine; 25 tons of spun cotton wicks; more than 50 tons of Japan wax; and 100 tons of wood. — We send to Great Britain annually fifteen millions of dollars to buy spool cotton. — The very conservative vestrymen in the London parish of St. George's, Hanover Square, have been roused to righteous indignation by certain measures of sanitary reform proposed within their precincts; and at a recent meeting one of the members, waxing rhetorical under excitement, protested against "the highly impertinent effort which had been made to force a new sewer down their throats!"

THE HALL TREADLE. — What is known as "the Hall Treadle" is really not one of the patent devices of the day which are of doubtful utility, but an invention well calculated to benefit every member of the household. By its use the labor of running sewing-machines is greatly reduced, and it contributes to the health and comfort of every person who uses them. It has received the warm commendations of all competent judges who have examined it, and it should be applied to every machine in use where steam power is not employed. It can be attached to the different kinds of machines, and the expense is so small that all may avail themselves of its benefits.

LITERARY NOTES.

THE Harpers have published Mr. Rolfe's edition of *Julius Cæsar*, the fourth of the annotated and illustrated series of Shakespeare's plays which he is preparing. Rev. E. A. Abbott, the author of the "Shakespearian Grammar," says of this series: "I have not seen any edition that compresses so much necessary information into so small a space, nor any that so completely avoids the common faults of commentaries on Shakespeare — needless repetition, superfluous explanation, and unscholarlike ignoring of difficulties." This is an important testimonial to the value of these little books, coming as it does from one who has a thorough acquaintance with the whole range of Shakespearian literature, and who has himself shown so much discrimination and taste in his criticism of the poet.

The same publishers have issued the *Annual Record of Science and Industry for* 1871, edited by Mr. Spencer F. Baird. It is an able and judicious compilation, and seems to us decidedly better in its way than the "Annual of Scientific Discovery," which we have more than once commended. It is a good feature in the editor's plan that he gives the authorities for the various items and notes, and thus makes the work of value to the scientific man for purposes of reference, as well as a useful summary of the year's progress in science for the general reader.

The Appletons have published *How the World was Peopled*, a series of "Ethnological Lectures," by Rev. Edward Fontaine, a work of no scientific value and of no interest whatever, except as an illustration of the rashness with which ignorant men sometimes presume to write on subjects that require eminent judgment as well as extensive study and research. Those who have neither knowledge nor wisdom are not likely to enlighten the world with regard to these great problems of modern science.

Less pretentious but intrinsically far more valuable books are the two little *Science Primers* just reprinted by the same house. One is on *Physics*, by Balfour Stewart, and the other on *Chemistry*, by Roscoe. We doubt, however, whether they are exactly adapted to the wants of American schools. They are too brief and elementary for high schools, and require too much apparatus for the lower grades of schools. As furnishing admirable hints for oral instruction and simple experiments to illustrate such lessons, they will be very suggestive and useful to teachers, even if they are not found available as text-books. They cost only fifty cents each.

A Woman's Experience in Europe, by Mrs. E. D. Wallace, published by the Appletons, is not so brilliant and sprightly as Miss Trafton's "American Girl Abroad," but it is nevertheless more entertaining than the average of books of travel. She has the woman's eye for things to which men are often blind, and a pleasant feminine way of telling them.

Messrs. Scribner, Armstrong, and Co. have added *A Miller's Story of the War* (otherwise known as "The Plebiscite") to their edition of the tales of MM. Erckmann-Chatrian. There are few historical fictions that are better worth reading than those from the double pen of these literary "Siamese twins." The same house reprint George Macdonald's *Within and Without*, a poem that is as charming as his novels, which is saying a good deal. All these books may be found at Noyes, Holmes, & Co's.

The *Popular Science Monthly* is a new magazine, edited by Prof. Youmans, and published by the Appletons at $5.00 a year. It is largely eclectic in its make-up, but contains some valuable original papers, with literary notices, miscellany, notes, etc. The first number is a very good one.

Medicine.

SEA-SICKNESS.

THE cause of sea-sickness, and the question of its curability, have both been the subject of a good deal of discussion. Some have asserted that it is always due to mere imagination or nervousness; but though this is undoubtedly a frequent cause of the malady, it is certain that it is not the invariable one. We have seen people sea-sick when the ship was moving more smoothly and steadily than a railway car, and it was easy to believe in that case that the expectation of the nausea was all that produced it. On the other hand, people who supposed themselves proof against an attack of the kind have been the victims of a sudden seizure. They neither feared nor anticipated anything of the kind, and it could not have been brought on by any mental cause whatever. Animals, moreover, are not exempt from sea-sickness. We have known a cat — not a "land-lubber" of a puss, but one of sea-going habits, that had crossed the Atlantic more than once — to be wretchedly sick in very rough weather; and we have heard of horses and dogs that were similarly affected. No one will assert that in these instances imagination had anything to do with the nausea.

Dr. Wollaston suggested, more than sixty years ago, that sea-sickness results from pressure of blood upon the brain; and it is well known that injury or pressure on the brain is almost invariably attended by vomiting, which is indeed its earliest symptom. Dr. Wollaston explains the way in which the pressure upon the brain is produced by the motion of a ship at sea, by reference to the action of mercury in the tube of a barometer. He says that "If a barometer be carried out to sea in a calm, the mercury will rest at the same height as when on shore; but when the ship falls by the subsidence of the waves, the mercury is seen apparently to rise in the tube which contains it." He considers that the action of the blood on the brain, at the moment of the descent of a ship, is identical with that of the mercury in the barometer, and that there is an actual pressure, and even a blow, which, by frequent repetition, produces nausea and vomiting. The action in both cases is due to the *inertia* of the liquid, which tends to remain where it *is*, and not to follow the movement of that which contains it; in other words, the mercury stays *up* when the barometer tube goes *down*. In like manner the blood tends to remain stationary when the head is carried downward, and the result is virtually the same as it would be if the blood were forced upward into the head. This produces an unnatural pressure upon the blood-vessels of the brain, and nausea and vomiting follow. This view is confirmed by the fact that the nausea is most marked when the ship is *descending*. Sir James Alderson, in a recent article on this subject in the *British Medical Journal*, states that this is the invariable experience of sufferers from sea-sickness, and he adds: —

"They are also conscious at that particular time of an instinctive effort to sigh, or take a deep inspiration, the meaning of which is manifest. During deep inspiration the chest is dilated for the reception of air, and its vessels become more open to admit blood, so that a return of blood from the head is then more free than at any other period of complete respiration; whilst, on the contrary, by the act of expelling air from the lungs, the ingress of blood is obstructed. This obstruction is proved by observation when the surface of the brain is exposed by the operation of trephining; a successive turgescence and subsidence of the brain is then seen in alternate motion with different states of the chest. A deep inspiration, therefore, at the time of the descent of the ship, tends to counteract the turgescence of the brain."

The sickness induced by waltzing is to be explained in a similar way. In this case, the blood is forced up into the brain by centrifugal force, just as a liquid tends to rise in a vessel that is whirled round rapidly. Swinging also sometimes causes nausea; and with regard to this Dr. Wollaston remarks as follows: —

"Sickness by swinging is evidently from the same cause as sea-sickness, and that direction of the motion which occasions the most piercing sensations of uneasiness, is conformable to the same explanation already given. It is descending forwards that this sensation is perceived, for then the blood has the greatest tendency to move from the feet towards the head, since the line joining them is in the direction of the motion; but when, in the descent backwards, the motion is transverse to the line of the body, it occasions but little inconvenience, because the tendency to propel the blood towards the head is then inconsiderable."

Now this may suggest how to alleviate sea-sickness, and perhaps to prevent it. If we know how the movement of the ship acts upon the brain, we see what must be done in order to neutralize the action. This, which Sir James Alderson considers "the only rational way of averting sea-sickness," we will give in his own words: —

"The first point is wholly to avoid the upright posture. Every one knows that it is a common practice to lie down, and this is done almost instinctively, but it is also known that to do so, though frequently successful, is not invariably so. The way in which the motion in a swing affects the brain affords the proper explanation why lying down is not invariably successful; and shows that it is necessary, not only to take a recumbent position, but to lie in the right direction. A person lying down with the feet towards the bows of a ship is, while it descends in pitching, in the same position as a person in a swing descending forwards, in which case we have seen that sickness is produced by blood being forced upon the brain. On the contrary, a person lying down with his head towards the bows is, during the descent of the ship, in the position of one descending backwards in a swing, in which case the pressure by the blood will be towards the feet, and, therefore, relief rather than an inconvenience will be experienced, the tendency being to reduce the natural supply of blood to the brain. It is necessary, not only to lie down, but to do so with the head to the bows; and it is highly desirable that this position should be assumed before the ship begins to move. There is a secondary advantage to be gained by closing the eyes, and so shutting out the confusion arising from the movement of surrounding objects."

THE SLOW ADVANCE OF MEDICAL SCIENCE.

THE following extract from General Bolles's Address contains some interesting illustrations of the slowness with which progress in practical medicine has been made; but in this respect its history does not materially differ from that of other departments of science. Important discov-

eries are often but imperfectly appreciated for many years after they are made, and practical applications of them are sometimes suggested long before any one carries them out. Of course, there are striking instances of the opposite kind, but that does not make the others less remarkable in their way.

Not until 1628, eight years after the landing at Plymouth, was the circulation of the blood discovered and demonstrated. The true *theory of respiration* was established at a still later day. Haller's "Elementa Physiologiæ Corporis Humani," in 1747, first presented anything worthy to be called the science of human physiology. Vaccination, that most blessed discovery in medicine, was made known by Jenner in 1798. In 1816 an accident gave to medicine and mankind the stethoscope, one of the most effective instruments of medical investigation. Lannec, the lucky discoverer and inventor, thus tells the story of his good fortune: "I happened to recollect the great distinctness with which we hear the scratch of a pin at one end of a piece of wood by applying our ear at the other end. I rolled a quire of paper into a kind of cylinder, applied one end of it to the patient's chest, and was surprised and pleased to find that I could perceive the sounds and vibrations of the heart's action more distinctly than I had ever been able to hear them by the immediate application of the ear." Not until 1846 was ether, or any other anæsthetic, admitted by the medical faculty as a legitimate portion of the *materia medica*. This application of anæsthetics and other recent medical discoveries was long ago hinted at and half known; and the delay of their full knowledge and adoption by physicians can be explained by no cause less discreditable than culpable carelessness. A hundred and ninety-one years before ether was adopted, Denis Papin, a French physicist and physician, suggested the use of anæsthetics to deaden pain in surgical operations. But no one acted on his suggestion. In 1795 Richard Pearson recommended the inhalation of sulphuric ether, and in 1800 Sir Humphry Davy spoke of *nitrous oxide* as adapted to this beneficent purpose. But no medical college or practitioner gave ear to this gospel of relief. For nearly half a century thereafter doctors talked occasionally, and occasionally wrote, about anæsthetics, but did not adopt and use them; and ether — divine handmaid of healing — was not authoritatively recognized until Morton, on the 16th day of October, 1846, in the Massachusetts Medical College, was allowed to administer it to a patient about to undergo a painful surgical operation. For nearly two hundred years after gunpowder was first used in European warfare, gunshot wounds were cauterized with boiling oil, to neutralize their supposed poison. An accidental discovery put an end to this cruel practice. In 1536 the illustrious Ambroise Paré, then an army surgeon, observed that wounded men who had, for lack of oil, escaped this horrible torture recovered more speedily and certainly than those who had been so cauterized. After that we hear no more of boiling oil for gunshot wounds. The same keen-eyed observer was the first surgeon who found out that a simple ligature would stop that flow of blood after amputation which had, till then, been checked by applying red-hot iron to the wounded surfaces; and this discovery led to the general abandonment of the old and barbarous method of treatment. It seems incredible that malpractices so coarse and cruel should have prevailed so long. Still stranger is it that customs of torture equally shocking have continued even to our own day. Dr. W. J. Walker informed me, some ten or twelve years ago, that when he entered the profession no surgeon's amputating saw in Boston, except his own, had its teeth either *set*, or so shaped and sharpened as to cut in both their forward and backward movements across the bone. Of course such saws as were in use would *bind* and jar horribly, and inflict unspeakable agonies upon the wretched victims subjected to their operation. What can be thought of surgeons who failed to see and know, or who, seeing and knowing, left unreformed, a mischief known to every wood-sawyer, and which the dullest apprentice would have discovered and remedied in half an hour's handling of his tools?

BOGUS MEDICAL COLLEGES.

HOW MEN ARE LICENSED TO MURDER — PROBABLE PUNISHMENT OF THE DIPLOMA-PEDDLERS.

THE licensed vice and incompetency in medical practitioners which the notorious Bowlesby case revealed, last summer, directed attention to various bogus diploma agencies in Philadelphia. Among the institutions which were exposed, were the University of Medicine and Surgery, in South Ninth Street, and the American University and the Eclectic Medical College, No. 339 South Seventh Street, both of Philadelphia, their heads being respectively Dr. Paine and Dr. John Buchanan. A reporter, assuming the part of a medical student unable to obtain a degree in England, communicated with the agent of Buchanan's College, in Brooklyn, and was told that for $100 he might have a diploma. Further investigation proved that a diploma might be obtained with the greatest facility, and in answer to a question of the reporter in his assumed character as to the nature of the examinations required, Dr. J. Dunbar Hylton naively declared: "O, they are not very severe. I first ask a few questions about antidotes to the principal poisons, and the other professors don't bore a man to death as they will do in some other colleges." Becoming desperate at the exposures, Hylton afterward wrote that in view of a contingency which he considered very remote, he "would sell diplomas for A. M., M. D., and H. D., to every saint or rascal in the land who had cash to buy, male or female, and when they were supplied, to the bears that roam the polar floes, to the birds that cut the liquid air, the fish, the dogs, and every breathing thing on earth."

While these colleges were chartered under the Pennsylvania laws, their faculties and lecturers had no existence except in the type of the elaborate prospectuses. A legislative committee in Philadelphia recently concluded an investigation into the bogus diploma trade, after having elicited abundant evidence to justify a revocation of the charters of Paine's and Buchanan's colleges. One of the latter's professors testified that he had blank diplomas, and "would sign one quicker than wink if he could make money by it." Buchanan himself admitted that one of his degrees had been sent to a man in consideration of a gift of $25 to the college; and a physician stated that he had bought a scholarship in Paine's University for $75, although he wrote no medical thesis and passed no examination; an "herb doctor" swore that Buchanan had presented him with a diploma as a "mark of honor." Another "doctor" received a diploma, his only qualification being that he "had been a janitor for seven years in the Baltimore Medical School." Several others testified to the like effect. The testimony given by James McShane is particularly ridiculous. He stated that he worked for Dr. Paine, and "did some work" for the "Eclectic;" he was no graduate, but, in Paine's establishment, he sometimes "ran the dissecting-room," and "acted as teacher;" he was also offered a professorship in the American University, then at Tenth and Chestnut Streets, and a "professorship of anatomy" in the "Eclectic;" he had been offered diplomas to sell, and had been asked by Dr. Paine to teach.

A strong feeling of resentment has been aroused in Philadelphia, and there is promise that not only will the charters of the infamous colleges be revoked, but Paine, Hylton, and Buchanan seem likely to be punished. — *New York Tribune.*

COLORED SPECTACLES.

THE following interesting note has been sent us by Dr. J. H. Stearns, U. S. Surgeon at the Asylum for Disabled Soldiers, Milwaukee, Wisconsin: —

The photographer uses orange-colored glass to exclude the actinic rays of light, and why some optician has not had the genius to see that orange is the proper color for spectacles instead of green or blue for persons of weak eyes, is beyond my comprehension.

A room in the hospital with which I am connected, is lighted through orange-colored windows, and is used for patients who have certain diseases of the eyes requiring the exclusion of the actinic rays of light. It has been very satisfactory. Orange, I believe, is also the proper color for bottles containing chemicals affected by the light.

MEDICAL MEMORANDA.

RE-IMPLANTATION OF TEETH. — At a recent meeting of the Odontological Society of England, Mr. Steele called the Society's attention to this subject, and stated that he recently had a tooth of his own extracted with great care. The tooth was in an exquisitely sensitive condition from exposure of the pulp, and gave pain on the least change of temperature. It was taken out under the influence of nitrous oxide gas; the dental canal was cleansed, and the carious portion of the crown was removed. After being stopped in the usual way, the tooth was replaced in its socket, the operation having lasted about half an hour.

TO PREVENT THE RUSTING OF STEEL INSTRUMENTS. — For this purpose the *Lancet* confidently recommends a mixture of equal parts of carbolic acid and olive oil, smeared over the surface of the instruments. This plan is much used by medical officers in the navy, and is found to preserve the polish and brightness of the steel, however moist and warm the climate may be.

A "PLUCKY" CHEMIST. — At Preston (England), Mr. Edward Foster, a chemist and druggist, has been summoned twelve consecutive times at the police court for not having his child vaccinated, and has paid heavy fines for not obeying the law in this particular. On each occasion he has addressed the bench in support of his conduct, opposing vaccination, and he asserts that he intends to resist to the end of the chapter.

HINTS ON DISPENSING MEDICINES. — A correspondent of the London *Chemist and Druggist*, in an article on this subject, gives the following suggestions concerning the preparation of ointments: —

"When you have an extract, such as belladonna, to mix with lard or any other fat, if you attempt to mix them together direct, there is considerable difficulty in getting a smooth ointment; but if you soften the extract first with a little hot water, and rub it smooth, then add the lard, or whatever it may be, you have no trouble.

"Glycerine is now frequently prescribed in ointments, and is difficult to mix. Well, supposing it to be ordered with Ung. Zinci, as is often the case, do not use ready-made zinc ointment, but weigh the proper quantity of oxide, rub the glycerine with it, and then add the lard; you have then a good smooth ointment, which does not separate; of course, the same plan can be adopted with any other powder. If there be no powder, melt the ointment, but do not let it get too hot, and beat the glycerine in and stir till cold; it then mixes much better, but still, if there be a large proportion of glycerine, it will separate after a time."

Physical Development in Old Times Compared with Our Own Day. — Mr. T. W. Higginson has taken pains to compare the vital statistics of several generations of two old New England families, and he finds, to the dismay of those who mourn the physical degeneracy of woman since the days of our great-grandmothers, that the stock has improved, if anything. He adds: —

"No man of middle age can look at a class of students from our older colleges without seeing them to be physically superior to the same number of college boys taken twenty-five years ago. The organization of the girls being far more delicate and complicated, the same reform reaches them less promptly, but it reaches them at last. The little girls of the present day eat better food, wear more healthful clothing, and breathe more fresh air than their mothers did. The introduction of india-rubber boots and water-proof cloaks alone has given a fresh lease of life to multitudes of women who otherwise would have been kept housed whenever it so much as sprinkled. It is desirable, certainly, to venerate our grandmothers, but I am inclined to think on the whole that their great-granddaughters will be the best."

Chloroform in the Treatment of Biliary Calculi. — Dr. John Barclay, in a communication to the *British Medical Journal*, mentions the case of a man who had suffered for twenty-three years from gall-stones, and knowing that ethers are solvents of cholesterine, he prescribed chloroform in doses of two or three drops three or four times a day, on the chance of reaching the calculi through the blood. The pain, tenderness, distension, and jaundice, all disappeared together, and in the eight years which have since elapsed, the patient has never had another attack.

MILK FOOD FOR INFANTS.

Dr. Fleetwood Churchill, in the last edition of his standard treatise on "Diseases of Children," discussing the subject of milk food for infants, says: "I have found an excellent milk food made by beating up an egg, with a pint of new milk and a pint of water, and putting it on the fire in a saucepan till it is on the point of boiling, then allowing it to cool, straining it if necessary, and adding sugar. It does not coagulate, and is seldom vomited. I learned its value from my friend, Dr. Halahan. Any of the milks [from cows, goats, etc.] thus modified will generally agree well with the child, and may form the staple food for some months; but feeding differs practically from nursing in this, that whilst a child will thrive upon mother's milk alone for nine months or a year, it seems absolutely necessary to change the *food* occasionally, or the child will suffer from derangement of the stomach and bowels.

"Dr. Dewees has laid down some very important rules for feeding with milk, a portion of which I shall extract: 1. The milk should be pure, *i. e.* not skimmed or previously reduced by water, and should be used as quickly as possible, especially in warm weather, after it has been drawn from the cow. 2. The milk should be given as soon as possible after its mixture with the water and sugar, lest it should be disposed to ferment before it is exhibited. 3. It should never be mixed but when wanted, and no more should be provided than the child will take in a short time; for it is much better to prepare fresh than to run the risk of its becoming sour before it is used. 4. In weather that is unfavorable for keeping milk, it should be placed in the coolest place that can be commanded, or kept in often-changed cold water. 5. Should the slightest tendency to acidity be observed in the milk, it should be rejected without hesitation, nor should an attempt be made at its supposed restoration, by using an additional quantity of sugar, as this will eventually but increase the evil."

SELECTED FORMULÆ.

A Good Diaphoretic. — Dr. S. C. Osborne, in the *American Practitioner*, highly commends the following formula, stating that in intermittent fever it is of great use, not only in shortening the paroxysm, but also in lessening the dose of quinine necessary to prevent relapse. The first dose usually nauseates for the hour, but after this nausea is absent, and the third dose rarely fails to induce profuse diaphoresis.

Take of Chloroformi Sp. etheris nitrosi Tinct. opii camphor Vini antimonii	āā fl℥ss.
Aquæ	fl℥vi.

Mix. S. For adults, teaspoonful every hour until the fever abates.

"Jackson's Cough Syrup." — According to the *Lancet and Observer*, the formula for this preparation has not been uniform, and therefore the Cincinnati College of Pharmacy has recently presented the subjoined one as a uniform standard: —

℞ Fl. ex. ipecac	ʒss.
Fl. ex. senegæ (℥j. Rad. Senegæ to f℥j)	ʒiij.
Fl. ex. rhei	ʒiv.
Syr. simplex	℥xxxj.
Morphiæ murias	gr. viij.
Ol. sassafras, guttæ	xxxij.

M. ft. mistura.

Hereafter, all prescriptions for this mixture will be prepared in that city on the above formula.

For Otitis. — The following is recommended by Dr. Brownrigg of Mississippi as a remedy in acute otitis: —

Take of Tobacco	ʒj. (cut fine.)
Glycerine	ʒj. M.

S. Five drops in the ear once a day.

For Tapeworm. — *L'Union Medicale* gives the following as Suvacher's formula: —

Take of Castor oil	60 grammes (15 ʒ by weight.)
Oil of turpentine	15 grammes (3.8 ʒ.)
Gum arabic	15 grammes (3.8 ʒ.)
Mint water	60 grammes (15 ʒ.)
Simple water	30 grammes (7.6 ʒ.)

Mix, and make a potion, to be taken early in the morning at one draught.

Glycerine of Tar. — The following is from the same authority: —

Take of Tar	150 parts.
Yellow of egg	150 "
Glycerine	300 "

Mix. This preparation is of the consistency of a pomade. It does not adhere to the skin, and may be diluted with water.

To Mask the Taste of Castor Oil. — According to a correspondent of the Boston *Medical and Surgical Journal*, the following formula affords a method of completely disguising castor oil: —

Glycerine, Ol. ricini, āā	f℥ij.
Ol. cinnam.	♏iv.

The essential oil should be rubbed up with the glycerine, the castor oil added, and the mixture well shaken before using.

The editor of that excellent quarterly, *New Remedies*, remarks that "This seems to be the best method of disguising castor oil yet devised."

Carminative Powder for Infants. — This is a Vienna recipe: —

Take of Fennel seed	25 grains.
Aniseed	50 "
Powdered sugar	350 "
Powdered opium	1 "

Make into a powder, ten grains of which will contain .02 grains of opium.

Tincture of Gelseminum in Tetanus. — In the *Baltimore Medical Journal* is recorded a recovery from tetanus, for which gelseminum was administered. The disease lasted seventeen days, during which time twenty ounces of the tincture were taken. During the first twelve days the patient took from half a drachm to two drachms every hour.

SOAP LINIMENT.

The officinal process for soap liniment, if the directions are strictly followed, is tedious and inconvenient. A writer in the *Journal of Pharmacy* suggests a change in the formula, by designating the alcohol as strong alcohol, and accordingly diminishing the volume one eighth, and doubling the quantity of water. He also changes the manipulation by bringing the soap into the form of No. 12 powder (easily obtained by simply sifting the dry soap shavings which accumulate so abundantly), adding all the prescribed water with one sixth the quantity of alcohol, and heating. "This," he says, "had the effect to dissolve the soap with marvellous rapidity, the application of heat for only a few moments sufficing to completely dissolve 24 troy ounces of dry soap, No. 12 powder, in a mixture of 3 pints of water and 8 fluid ounces of strong alcohol. From this result, and by increasing the officinal formula 6 times, the following process is derived: —

Take of soap (genuine Castile, mottled or white), dry and in No. 12 powder	24 troy ounces.
Camphor	12 " "
Oil of rosemary	3 fluid ounces.
Water	3 pints.
Strong alcohol	10½ "

Mix the water with half a pint of the alcohol in a capacious vessel; add the soap and apply heat until solution has occurred; to this add 4 pints of alcohol. In the remaining 6 pints of alcohol dissolve the camphor and oil; to this add the solution of soap; mix. Let the impurities (coloring matter of the soap) subside, and filter."

A correspondent of the *Pharmacist* suggests the following method of preparing this liniment with the officinal materials but modified manipulation, the object being to obviate the use of heat, and expedite the process. The result will be preferable to the officinal, in that it will be less liable to gelatinize in cold weather: —

Take of soap, in small pieces	4 troy ounces.
Camphor	2 " "
Oil of rosemary	½ fluid drachm.
Water	4 fluid ounces.
Alcohol	2 pints.

Beat the soap in a dry mortar until the lumps have disappeared; then add by degrees the water and triturate; when well mixed add the alcohol gradually, afterwards the camphor and oil of rosemary, rubbing with the pestle till all are dissolved, and filter.

MEDICINAL AGENTS NEW AND OLD.

The publishers of the Journal, Messrs. J. R. Nichols & Co., will send free of cost to any physician or druggist in the United States, their new book, "*Chemical and Therapeutical Agents, New and Old, Officinal and Unofficinal.*" Those who write for it will receive it by return of mail. It contains, in addition to a description of medicinal agents new and old, a treatise upon "Chemical Examination of Urine," which, as it treats the subject in a plain and familiar style, is of much interest to physicians.

Cincho-Quinine. — Dr. D. L. Krebs, Elizabeth City, N. C., under date of May 6, 1872, writes as follows of *cincho-quinine*: —

"I have refrained from recommending cincho-quinine, because I did not wish to reach a hasty conclusion regarding it. I was the first to use it in this section, and now I desire to speak of it in terms of high commendation. I have used it for the last five months instead of the sulphate, and as an anti-periodic it has not failed in a single instance when given in the same doses as the sulphate. It is almost tasteless, and can be used in a large number of cases where sulphate of quinine is found to be inadmissible."

INDEX.
